1.1.2 Welcome

Welcome to my collection titled *Object-Oriented Programming (OOP) with Java* .

During the past nineteen years, I have published hundreds of Java and OOP programming tutorials on a variety of different topics and websites. I have also developed the teaching materials for several different college-level programming courses in Java/OOP.

A work in progress

This is a work in progress. I am currently combining selected content from those earlier endeavors with new material that I am developing to create a freely downloadable Book that covers Java/OOP programming from programming fundamentals to very advanced OOP concepts.

Among other things, the collection contains the material that I use to teach the following courses at Austin Community College in Austin Texas:

- ITSE 2321 - Object-Oriented Programming (Java) ²
- ITSE2317 - Java Programming (Intermediate) ³
- INEW2338 - Advanced Java Programming ⁴
- GAME 2302 Mathematical Applications for Game Development ⁵

The collection also includes:

¹This content is available online at <<http://cnx.org/content/m45136/1.19/>>.

²http://cnx.org/contents/-2RmHFs_:6GrxCfXx

³http://cnx.org/contents/-2RmHFs_:JVTd7bX1

⁴http://cnx.org/contents/-2RmHFs_:boF3E5Bs

⁵http://cnx.org/contents/Ki_nRUo6:SGyUbirS

- An OOP self-assessment test ⁶
- Course materials for a complete course in Programming Fundamentals ⁷

Because it is a work in progress, the collection is growing on a daily basis. If you don't find what you need today, come back and take another look in a week or two and you may find what you need then.

Download options

I encourage you to take advantage of all of the download options (*most of which are free*) that cnx.org ⁸ has to offer. You can also customize this material for use in your organized courses or for personal self study.

Feedback is appreciated

And if you find the material useful, I would like to hear more about how you are using it.

Legacy versus openstax presentation format Early in 2014, cnx.org ⁹ began a transition from a legacy presentation format ¹⁰ to a new openstax ¹¹ presentation format. As of January 8, 2016, some of the functionality of the legacy presentation format has not yet been ported to the **openstax** presentation format.

If you find yourself viewing one of my collections or modules in the openstax ¹² presentation format and some of the links appear to be broken, some of the images fail to display properly, etc., you may need to revert to the legacy presentation format ¹³ .

You can switch from **openstax** format to **legacy** format by selecting the **Legacy Site** link in the upper-right corner of the page when viewing a collection or module in **openstax** format.

When you are viewing a module in the **legacy** format, you can switch to the **openstax** format by selecting a link that normally appears at the beginning of the page and reads something like the following: *"Note: You are viewing an old style version of this document. The new style version is available here."*

Terminology: The folks at cnx.org ¹⁴ have adopted some new terminology in conjunction with this transition. For example, the entity that is referred to as a **Collection** in the **legacy** format is referred to as a **Book** in the **openstax** format. The entity that is referred to as a **Module** in the legacy format is referred to as a **Page** in the **openstax** format. You will probably find that I use these terms somewhat interchangeably in this material.

The landing module or page: It is possible to open and view material at the level of a **Collection** in the **legacy** format as shown here ¹⁵ . However, (*with some exceptions*) when you open a **Book** in the **openstax** format, you will actually land on the first **Page** in the book as shown here ¹⁶ . In other words, a Book is not a "stand alone" entity in the **openstax** format.

1.1.3 Getting started with Java programming

As is the case with many worthwhile endeavors, Java programming requires that you have some tools to begin. Fortunately, all of the software tools that you will need to get started programming in Java are available for free downloading.

In addition to a computer with web access, you will need:

- The Java Development Kit (*JDK*) and Java Runtime Engine (*JRE*)
- The Java API documentation
- A suitable text editor

1.1.3.1 The JDK and the JRE

The JDK, the JRE, and the API documentation are all freely available from Oracle. As of January 2016, you will find links to the documentation on the web page titled *Java Platform Standard Edition 8 Documentation*¹⁷. (*The links given in this module may change as new versions of Java are released, but newer versions shouldn't be too difficult to locate with a web search.*)

Download

The JDK and the included JRE can be downloaded from <http://www.oracle.com/technetwork/java/javase/downloads/index.html>

¹⁸ That page provides several download options. Beginners should download the **Java Platform (JDK)** for the latest released version. (*The JRE is included in the JDK package, so you don't need to download both.*)

Install

You will also probably need to follow the installation instructions¹⁹ for your computer. Pay particular attention to the instructions for setting the *path* and *classpath* environment variables. This is where many students stumble. Another useful document on the path and classpath is available at <http://docs.oracle.com/javase/tutorial/essential/environment/paths.html>²⁰

1.1.3.2 The Java API documentation

The Java Platform, Standard Edition 8 API Specification is available here²¹. You should be able to find the documentation for later versions with a web search.

Also see my Java OOP documentation²² module for instructions on how to use the documentation.

1.1.3.3 A suitable text editor

The module titled Jb0110: Java OOP: Programming Fundamentals, Getting Started²³ explains how to use a text editor to create Java program code. Just about any text editor will do as long as you can ensure that the file name extension is *.java*. Something as simple as *Windows Notepad* or *Windows WordPad* would probably be best for your first few simple programs.

Soon, however, you will probably want to upgrade to an editor that uses different colors to identify the different parts of your program. My favorite color-coded editor is the free version of JCreator²⁴. (*The free version seems to have disappeared from their web page so you may have trouble finding it.*)

Another free editor is DrJava²⁵. An advantage of this editor is that it can be run from a USB drive with no installation required. Another possibility, although I have never had occasion to use it, is jGRASP²⁶. Numerous other Java color-coded editors, including BlueJ²⁷ are available for free downloading on the web.

2.1.2 Welcome

Welcome to Programming Fundamentals with Java.

This book is a compilation of material that I have published over the years for the benefit of those students who desire to enroll in my beginning OOP course but who don't have the required prerequisite knowledge for that course. If you fall in that category, or if you just want to get a good introduction to computer programming, you may find this material useful.

Even if you have completed a programming fundamentals course in another language, or you have considerable programming experience in another language, you may still find this material useful as an introduction to the Java programming language and its syntax.

In case you decide that you don't need to study the material in this group of modules, you may still find it useful to take a look at the following three modules. These three modules will show you how to configure your computer and get started programming in Java.

- Jb0110: Java OOP: Programming Fundamentals, Getting Started⁴
- Jb0110r Review⁵

- Jb0115: Java OOP: First Program ⁶

You may also find it useful to search the web for and study a few tutorials on the Windows "command prompt" as well as a few tutorials on Windows batch files. Here are a couple of possibilities that I found with a rudimentary search:

- Windows Command Prompt in 15 Minutes ⁷
- Windows Batch Scripting: Getting Started ⁸

If you are using a different operating system, you may need to find similar tutorials that match up with the operating system that you are using.

Most of the topics in this Book are divided into two modules – a primary module and a review module. The review modules contain review questions and answers keyed to the material in the primary modules.

In addition to the modules contained in this group, you will find several of my other tutorials on programming fundamentals at Obg0510: Programming Fundamentals ⁹. Those tutorials are still in their original html format and you may need to go to the Legacy Site ¹⁰ to access them fully. They are awaiting conversion to cnxml, which is a requirement for publishing them as modules on cnx.org.

As you work your way through the modules in this group, you should prepare yourself for the more challenging ITSE 2321 OOP tracks identified below:

- Java 1600: Objects and Encapsulation ¹¹
- Java 3000: The Guzdial-Ericson Multimedia Class Library ¹²
- Java 4010: Getting Started with Java Collections ¹³

2.1.3 The DrJava IDE and the Java Development Kit

In order to work with the material in this group of *Programming Fundamentals* modules, you will need access to Oracle's Java Development Kit ¹⁴ (*JDK*). You will also need access to a text editor, preferably one that is tailored to the creation of Java programs. One such freely available text editor is named DrJava ¹⁵.

However, DrJava is more than just a text editor. It is an Integrated Development Environment (*IDE*) that is designed for use by students learning how to program in the Java programming language. I recommend it for use with this group of *Programming Fundamentals* modules.

See A Quick Start Guide to DrJava ¹⁶ for instructions on downloading and installing both the DrJava IDE and Oracle's Java Development Kit (*JDK*).

The Quick Start Guide also provides instructions for using the DrJava IDE.

2.2 Jb0105: Java OOP: Similarities and Differences between Java and C++¹⁷

Revised: Sun Mar 27 11:30:53 CDT 2016

This Page is included in the following Books:

- *Programming Fundamentals with Java*¹⁸
- *Object-Oriented Programming (OOP) with Java*¹⁹

2.2.1 Table of Contents

- Preface (p. 7)
- Similarities and differences (p. 8)
- Miscellaneous (p. 11)

2.2.2 Preface

This module, which presents some of the similarities and differences between Java and C++, is provided solely for the benefit of those students who are already familiar with C++ and are making the transition from C++ into Java.

If you have some familiarity with C++, you may find the material in this module helpful. If not, simply skip this module and move on to the next module in the collection.

In general, students in Prof. Baldwin's Java/OOP courses are not expected to have any specific knowledge of C++.

¹⁷This content is available online at <<http://cnx.org/content/m45142/1.4/>>.

¹⁸<http://cnx.org/contents/EHRr6hjR:pDHZTeQb>

¹⁹http://cnx.org/contents/-2RmHF_s:_kFS-maG_

This module is intended to be general in nature. Therefore, although a few update notes were added prior to publication at cnx.org, no significant effort has been made to keep it up to date relative to any particular version of the Java JDK or any particular version of C++. Changes have occurred in both Java and C++ since the first publication of this document in 1997. Those changes may not be reflected in this module.

2.2.3 Similarities and differences

This list of similarities and differences is based heavily on The Java Language Environment, A White Paper ²⁰ by James Gosling and Henry McGilton and *Thinking in Java* by Bruce Eckel, which was freely available on the web when this document was first published.

Java does not support **typedefs** , **defines** , or a **preprocessor** . Without a preprocessor, there are no provisions for including header files.

Since Java does not have a preprocessor there is no concept of **#define** macros or *manifest constants* . However, the declaration of named constants is supported in Java through use of the **final** keyword.

Java does not support **enums** but, as mentioned above, does support *named constants* . (*Note: the enum type* ²¹ *was introduced into Java sometime between the first publication of this document and Java version 7.*)

Java supports *classes* , but does not support *structures* or *unions* .

All stand-alone C++ programs require a function named **main** and can have numerous other functions, including both stand-alone functions and functions that are members of a class. There are no stand-alone functions in Java. Instead, there are only functions that are members of a class, usually called methods. However, a Java application (*not a Java applet*) does require a class definition containing a **main** method.

Global functions and global data are not allowed in Java. However, variables that are declared **static** are shared among all objects instantiated from the class in which the **static** variables are declared. (*Generally, static has a somewhat different meaning in C++ and Java. For example, the concept of a static local variable does not exist in Java as it does in C++.*)

All classes in Java ultimately inherit from the class named **Object** . This is significantly different from C++ where it is possible to create inheritance trees that are completely unrelated to one another. All Java objects contain the eleven methods that are inherited from the **Object** class.

All function or method definitions in Java are contained within a class definition. To a C++ programmer, they may look like inline function definitions, but they aren't. Java doesn't allow the programmer to request that a function be made inline, at least not directly.

Both C++ and Java support class (*static*) methods or functions that can be called without the requirement to instantiate an object of the class.

The **interface** keyword in Java is used to create the equivalence of an abstract base class containing only method declarations and constants. No variable data members or method definitions are allowed in a Java interface definition. (*True abstract base classes can also be created in Java.*) The interface concept is not supported by C++ but can probably be emulated.

Java does not support multiple class inheritance. To some extent, the **interface** feature provides the desirable features of multiple class inheritance to a Java program without some of the underlying problems.

While Java does not support multiple class inheritance, single inheritance in Java is similar to C++, but the manner in which you implement inheritance differs significantly, especially with respect to the use of constructors in the inheritance chain.

In addition to the access modifiers applied to individual members of a class, C++ allows you to provide an additional access modifier when inheriting from a class. This latter concept is not supported by Java.

Java does not support the **goto** statement (*but goto is a reserved word*) . However, it does support labeled **break** and **continue** statements, a feature not supported by C++. In certain restricted situations, labeled **break** and **continue** statements can be used where a **goto** statement might otherwise be used.

²⁰<http://net.uom.gr/Books/Manuals/langenviron-a4.pdf>

²¹<http://docs.oracle.com/javase/tutorial/java/javaOO/enum.html>

Java does not support **operator overloading** .

Java does not support automatic type conversions (*except where guaranteed safe*) .

Unlike C++, Java has a **String** type, and objects of this type are immutable (*cannot be modified*) . (Note, although I'm not certain, I believe that the equivalent of a Java String type was introduced into C++ sometime after the original publication of this document.)

Quoted strings are automatically converted into **String** objects in Java. Java also has a **StringBuffer** type. Objects of this type can be modified, and a variety of string manipulation methods are provided.

Unlike C++, Java provides true arrays as first-class objects. There is a length member, which tells you how big the array is. An exception is thrown if you attempt to access an array out of bounds. All arrays are instantiated in dynamic memory and assignment of one array to another is allowed. However, when you make such an assignment, you simply have two references to the same array. Changing the value of an element in the array using one of the references changes the value insofar as both references are concerned.

Unlike C++, having two "pointers" or references to the same object in dynamic memory is not necessarily a problem (*but it can result in somewhat confusing results*) . In Java, dynamic memory is reclaimed automatically, but is not reclaimed until all references to that memory become NULL or cease to exist. Therefore, unlike in C++, the allocated dynamic memory cannot become invalid for as long as it is being referenced by any reference variable.

Java does not support **pointers** (*at least it does not allow you to modify the address contained in a pointer or to perform pointer arithmetic*) . Much of the need for pointers was eliminated by providing types for arrays and strings. For example, the oft-used C++ declaration **char* ptr** needed to point to the first character in a C++ null-terminated "string" is not required in Java, because a string is a true object in Java.

A class definition in Java looks similar to a class definition in C++, but there is no closing semicolon. Also *forward reference declarations* that are sometimes required in C++ are not required in Java.

The scope resolution operator (::) required in C++ is not used in Java. The dot is used to construct all fully-qualified references. Also, since there are no pointers, the pointer operator (->) used in C++ is not required in Java.

In C++, static data members and functions are called using the name of the class and the name of the static member connected by the scope resolution operator. In Java, the dot is used for this purpose.

Like C++, Java has primitive types such as **int** , **float** , etc. Unlike C++, the size of each primitive type is the same regardless of the platform. There is no unsigned integer type in Java. Type checking and type requirements are much tighter in Java than in C++.

Unlike C++, Java provides a true **boolean** type. (Note, the C++ equivalent of the Java boolean type may have been introduced into C++ subsequent to the original publication of this document.)

Conditional expressions in Java must evaluate to **boolean** rather than to integer, as is the case in C++. Statements such as

```
if(x+y)...
```

are not allowed in Java because the conditional expression doesn't evaluate to a **boolean** .

The **char** type in C++ is an 8-bit type that maps to the ASCII (*or extended ASCII*) character set. The **char** type in Java is a 16-bit type and uses the Unicode character set (*the Unicode values from 0 through 127 match the ASCII character set*) . For information on the Unicode character set see <http://www.unicode.org/>²² .

Unlike C++, the >> operator in Java is a "signed" right bit shift, inserting the sign bit into the vacated bit position. Java adds an operator that inserts zeros into the vacated bit positions.

C++ allows the instantiation of variables or objects of all types either at compile time in static memory or at run time using dynamic memory. However, Java requires all variables of primitive types to be instantiated at compile time, and requires all objects to be instantiated in dynamic memory at runtime. Wrapper classes are provided for all primitive types to allow them to be instantiated as objects in dynamic memory at runtime if needed.

C++ requires that classes and functions be declared before they are used. This is not necessary in Java.

²²<http://www.unicode.org/>

The "namespace" issues prevalent in C++ are handled in Java by including everything in a class, and collecting classes into packages.

C++ requires that you re-declare static data members outside the class. This is not required in Java.

In C++, unless you specifically initialize variables of primitive types, they will contain garbage. Although local variables of primitive types can be initialized in the declaration, primitive data members of a class cannot be initialized in the class definition in C++.

In Java, you can initialize primitive data members in the class definition. You can also initialize them in the constructor. If you fail to initialize them, they will be initialized to zero (or equivalent) automatically.

Like C++, Java supports constructors that may be overloaded. As in C++, if you fail to provide a constructor, a default constructor will be provided for you. If you provide a constructor, the default constructor is not provided automatically.

All objects in Java are passed by reference, eliminating the need for the copy constructor used in C++.

(In reality, all parameters are passed by value in Java. However, passing a copy of a reference variable makes it possible for code in the receiving method to access the object referred to by the variable, and possibly to modify the contents of that object. However, code in the receiving method cannot cause the original reference variable to refer to a different object.)

There are no destructors in Java. Unused memory is returned to the operating system by way of a *garbage collector*, which runs in a different thread from the main program. This leads to a whole host of subtle and extremely important differences between Java and C++.

Like C++, Java allows you to overload functions (*methods*). However, default arguments are not supported by Java.

Unlike C++, Java does not support templates. Thus, there are no generic functions or classes. *(Note, generics similar to C++ templates were introduced into Java in version 5 subsequent to the original publication of this document.)*

Unlike C++, several "data structure" classes are contained in the "standard" version of Java. *(Note, the Standard Template Library was introduced into the C++ world subsequent to the original publication of this document.)*

More specifically, several "data structure" classes are contained in the standard class library that is distributed with the Java Development Kit (JDK). For example, the standard version of Java provides the containers **Vector** and **Hashtable** that can be used to contain any object through recognition that any object is an object of type **Object**. However, to use these containers, you must perform the appropriate upcasting and downcasting, which may lead to efficiency problems. *(Note, the upcasting and downcasting requirements were eliminated in conjunction with the introduction of "generics" into Java mentioned earlier.)*

Multithreading is a standard feature of the Java language.

Although Java uses the same keywords as C++ for access control: **private**, **public**, and **protected**, the interpretation of these keywords is significantly different between Java and C++.

There is no **virtual** keyword in Java. All non-static methods use dynamic binding, so the virtual keyword isn't needed for the same purpose that it is used in C++.

Java provides the **final** keyword that can be used to specify that a method cannot be overridden and that it can be statically bound. *(The compiler may elect to make it inline in this case.)*

The detailed implementation of the exception handling system in Java is significantly different from that in C++.

Unlike C++, Java does not support operator overloading. However, the (+) and (+=) operators are automatically overloaded to concatenate strings, and to convert other types to string in the process.

As in C++, Java applications can call functions written in another language. This is commonly referred to as *native methods*. However, applets cannot call native methods.

Unlike C++, Java has built-in support for program documentation. Specially written comments can be automatically stripped out using a separate program named **javadoc** to produce program documentation.

Generally Java is more robust than C++ due to the following:

- Object handles (*references*) are automatically initialized to null.
- Handles are checked before accessing, and exceptions are thrown in the event of problems.

- You cannot access an array out of bounds.
- The potential for memory leaks is prevented (or at least greatly reduced) by automatic garbage collection.

2.3.2 Preface

2.3.2.1 General

This module is part of a sub-collection of modules designed to help you learn to program computers.

This module explains how to get started programming using the Java programming language.

2.3.2.2 Prerequisites

In addition to an Internet connection and a browser, you will need the following tools (*as a minimum*) to work through the exercises in these modules:

- The Sun/Oracle Java Development Kit (JDK) (*See <http://www.oracle.com/technetwork/java/javase/downloads/index.html>*²⁶)
- Documentation for the Sun/Oracle Java Development Kit (JDK) (*See <http://download.oracle.com/javase/7/docs/api/>*²⁷ or the documentation for the latest version of the *JDK*.)
- A simple IDE or text editor for use in writing Java code.

The minimum prerequisites for understanding the material in these modules include:

- An understanding of algebra.
- An understanding of all of the material covered in the earlier modules in this Book.

2.3.2.3 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the listings while you are reading about them.

2.3.2.3.1 Listings

- Listing 1 (p. 14) . Windows batch file.
- Listing 2 (p. 15) . A test program.

2.3.3 Writing, compiling, and running Java programs

2.3.3.1 Writing Java code

Writing Java code is straightforward. You can write Java code using any plain text editor. You simply need to cause the output file to have an extension of `.java`.

There are a number of high-level *Integrated Development Environments (IDEs)* available, such as Eclipse and NetBeans, but they tend to be overkill for the relatively simple Java programs described in these modules.

There are also some low-level IDEs available, such as JCreator and DrJava, which are very useful. I normally use a free version of JCreator, mainly because it contains a color-coded editor.

So, just find an editor that you are happy with and use it to write your Java code.

2.3.3.2 Preparing to compile and run Java code

Perhaps the most complicated thing is to get your computer set up for compiling and running Java code in the first place.

2.3.3.2.1 Downloading the java development kit (*JDK*)

You will need to download and install the free Java JDK from the Oracle/Sun website. As of November, 2012, you will find that website at <http://www.oracle.com/technetwork/java/javase/downloads/index.html>²⁸

There is a 64-bit version of the JDK, which works well on my home computer and on my office computer. However, some older computers may not be able to handle the 64-bit version. A 32-bit version is provided to be used on older computers.

Whether you elect to use the 32-bit or 64-bit version is strictly up to you. Either of them should do the job very nicely.

2.3.3.2.2 Installing the JDK

As of November 2012, you will find installation instructions at <http://download.oracle.com/javase/7/docs/webnotes/install/windows/jdk-installation-windows.html>²⁹

I strongly recommend that you read the instructions and pay particular attention to the information having to do with setting the **path** environment variable.

A word of caution

If you happen to be running Windows Vista or Windows 7, you may need to use something like the following when updating the PATH Environment Variable

```
... ;C:\Program Files (x86)\Java\jdk1.6.0_26\bin
```

in place of

```
... ;C:\Program Files\Java\jdk1.7.0\bin
```

as shown in the installation instructions.

I don't have any experience with any Linux version. Therefore, I don't have any hints to offer there.

²⁸<http://www.oracle.com/technetwork/java/javase/downloads/index.html>

²⁹<http://download.oracle.com/javase/7/docs/webnotes/install/windows/jdk-installation-windows.html>

2.3.3.2.3 The JDK documentation

It is very difficult to program in Java without access to the documentation for the JDK.

Several different types of Java documentation are available online at <http://www.oracle.com/technetwork/java/javase/documentation/index.html> ³⁰.

Specific documentation for classes, methods, etc., is available online at <http://download.oracle.com/javase/7/docs/api/> ³¹.

It is also possible to download the documentation and install it locally if you have room on your disk. The download links for JDK 6 and JDK 7 documentation are also shown on the page at <http://www.oracle.com/technetwork/java/javase/downloads/index.html> ³².

You may also want to search for and use the documentation for the latest version of the JDK.

2.3.3.3 Compiling and running Java code

There are a variety of ways to compile and run Java code. The way that I will describe here is the most basic and, in my opinion, the most reliable. These instructions apply to a Windows operating system. If you are using a different operating system, you will need to translate the instructions to your operating system.

2.3.3.3.1 Write your Java program

Begin by using your text editor to write your Java program into one or more text files, each with an extension of `.java`. (*Files of this type are often referred to as source code files.*) Save the source code files in an empty folder somewhere on your disk. Make sure that the name of the **class** containing the **main** method (*which you will learn about in a future module*) matches the name of the file in which that class is contained (*except for the extension of `.java` on the file name, which does not appear in the class name*).

2.3.3.3.2 Create a batch file

Use your text editor to create a batch file (*or whatever the equivalent is for your operating system*) containing the text shown in Listing 1 (p. 14) (*with the modifications discussed below*) and store it in the same folder as your Java source code files..

Then execute the batch file, which in turn will execute the program if there are no compilation errors.

Listing 1 . Windows batch file.

```
echo off
cls

del *.class

javac -cp .; hello.java
java -cp .; hello

pause
```

Table 2.1

³⁰<http://www.oracle.com/technetwork/java/javase/documentation/index.html>

³¹<http://download.oracle.com/javase/7/docs/api/>

³²<http://www.oracle.com/technetwork/java/javase/downloads/index.html>

Comments regarding the batch file

The commands in the batch file of Listing 1 (p. 14) will

- Open a command-line screen for the folder containing the batch file.
- Delete all of the compiled class files from the folder. (*If the folder doesn't contain any class files, this will be indicated on the command-line screen.*)
- Attempt to compile the program in the file named **hello.java**.
- Attempt to run the compiled program using a compiled Java file named **hello.class** .
- Pause and wait for you to dismiss the command-line screen by pressing a key on the keyboard.

If errors occur, they will be reported on the command-line screen and the program won't be executed.

If your program is named something other than **hello** , (*which it typically would be*) substitute the new name for the word **hello** where it appears twice in the batch file.

Don't delete the pause command

The **pause** command causes the command-line window to stay on the screen until you dismiss it by pressing a key on the keyboard. You will need to examine the contents of the window if there are errors when you attempt to compile and run your program, so don't delete the pause command.

Translate to other operating systems

The format of the batch file in Listing 1 (p. 14) is a Windows format. If you are using a different operating system, you will need to translate the information in Listing 1 (p. 14) into the correct format for your operating system.

2.3.3.3.3 A test program

The test program in Listing 2 (p. 15) can be used to confirm that Java is properly installed on your computer and that you can successfully compile and execute Java programs.

Listing 2 . A test program.

```
class hello {
public static void main(String[] args){
    System.out.println("Hello World");
} //end main
} //end class
```

Table 2.2

Instructions

Copy the code shown in Listing 2 (p. 15) into a text file named **hello.java** and store in an empty folder somewhere on your disk.

Create a batch file named **hello.bat** containing the text shown in Listing 1 (p. 14) and store that file in the same folder as the file named **hello.java** .

Execute the batch file.

If everything is working, a command-line screen should open and display the following text:

```
Hello World
Press any key to continue . . .
```

Congratulations

If that happens, you have just written, compiled and executed your first Java program.

Oops

If that doesn't happen, you need to go back to the installation instructions and see if you can determine why the JDK isn't properly installed.

If you get an error message similar to the following, that probably means that you didn't set the **path** environment variable correctly.

```
'javac' is not recognized as an internal or external command,  
operable program or batch file.
```

Beyond that, I can't provide much advice in the way of troubleshooting hints.

2.4.5 Answers

2.4.5.1 Answer 6

If you can compile and run the program code shown in Listing 1 (p. 19) , the JDK is probably installed properly on your computer.

Listing 1 . A Java test program.

```
class hello {

    }//end main  
}//end class
```

Table 2.3

Back to Question 6 (p. 18)

2.4.5.2 Answer 5

True. Although a variety of IDEs are available that can be used to compile and run Java applications, the most fundamental way is to compile and run the programs from the command line. A batch file in Windows,

or the equivalent in other operating systems, can be of some help in reducing the amount of typing required to compile and run a Java application from the command line.

Back to Question 5 (p. 18)

2.4.5.3 Answer 4

False. Java uses huge class libraries, which few if any of us can memorize. Therefore, it is very difficult to program in Java without access to the documentation for the JDK.

As of November 2012, several different types of Java documentation are available online at <http://www.oracle.com/technetwork/java/javase/documentation/index.html>³⁷.

Back to Question 4 (p. 17)

2.4.5.4 Answer 3

True. Installing the Java JDK can be a little difficult depending on your experience and knowledge. As of November 2012, you will find installation instructions at <http://download.oracle.com/javase/7/docs/webnotes/install/windows/jdk-installation-windows.html>³⁸.

Back to Question 3 (p. 17)

2.4.5.5 Answer 2

True. You will need to download and install the **free** Java JDK from the Oracle/Sun website. As of November, 2012, you will find that website at <http://www.oracle.com/technetwork/java/javase/downloads/index.html>³⁹.

Back to Question 2 (p. 17)

2.5.3 Discussion

2.5.3.1 Instructions for compiling and running the program

Assuming that the Java Development Kit (JDK) is properly installed on your computer (see *Jb0110: Java OOP: Programming Fundamentals, Getting Started*⁴³), do the following to compile and run this program.

1. Copy the text from Listing 1 (p. 24) into a text file named **FirstProgram.java** and store the file in a folder on your disk.
2. Open a command-line window in the folder containing the file.
3. Type the following command at the prompt to compile the program:

```
javac FirstProgram.java
```

4. Type the following command at the prompt to run the program:

```
java FirstProgram
```

2.5.3.2 Comments

Any text in the program code that begins with `//` is a comment. The compiler will ignore everything from the `//` to the end of the line.

Comments were inserted into the program code to explain the code.

The compiler also ignores blank lines.

Note that this program was designed to illustrate the concepts while being as non-cryptic as possible.

2.5.3.3 Program output

The program should display the text shown in Figure 1 (p. 23) on the screen except that the time will be different each time you run the program.

2.5.4 Run the program

I encourage you to copy the code from Listing 1 (p. 24) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

2.6.3 Discussion and sample code

2.6.3.1 Introduction

All data is stored in a computer in numeric form. Computer programs do what they do by executing a series of calculations on numeric data. It is the order and the pattern of those calculations that distinguishes one computer program from another.

Avoiding the detailed work

Fortunately, when we program using a high-level programming language such as Java, much of the detailed work is done for us behind the scenes.

Musicians or conductors

As programmers, we are more like conductors than musicians. The various parts of the computer represent the musicians. We tell them what to play, and when to play it, and if we do our job well, we produce a solution to a problem.

2.6.3.2 Compartments

As the computer program performs its calculations in the correct order, it is often necessary for it to store intermediate results someplace, and then come back and get them to use them in subsequent calculations later. The intermediate results are stored in memory, often referred to as RAM or *Random Access Memory*.

A mechanical analogy

We can think of random access memory as being analogous to a metal rack containing a large number of compartments. The compartments are all the same size and are arranged in a column. Each compartment has a numeric address printed above it. No two compartments have the same numeric address. Each compartment also has a little slot into which you can insert a name or a label for the compartment. No two compartments can have the same name.

Joe, the computer program

Think of yourself as a computer program. You have the ability to write values on little slips of paper and to put them into the compartments. You also have the ability to read the values written on the little slips of paper and to use those values for some purpose. However, there are two rules that you must observe:

- You may not remove a slip of paper from a compartment without replacing it by another slip of paper on which you have written a value.
- You may not put a slip of paper in a compartment without removing the one already there.

2.6.3.3 Checkout counter example

In understanding how you might behave as a human computer program, consider yourself to have a job working at the checkout counter of a small grocery store in the 1930s.

You have two tools to work with:

- A mechanical adding machine
- The rack of compartments described above

Initialization

Each morning, the owner of the grocery store tells you to insert a name in the slot above each compartment and to place a little slip of paper with a number written on it inside each compartment. (*In programming jargon, we would refer to this as initialization.*)

Each of the names on the compartments represents a type of grocery such as

- Beans
- Apples

- Pears

No two compartments can have the same name.

No compartment is allowed to have more than one slip of paper inside it.

The price of a can of beans

When you place a new slip of paper in a compartment, you must be careful to remove and destroy the one that was already there.

Each slip of paper that you insert into a compartment contains the price for the type of grocery identified by the label on the compartment.

For example, the slip of paper in the compartment labeled **Beans** may contain the value 15, meaning that each can of beans costs 15 cents.

The checkout procedure

As each customer comes to your checkout counter during the remainder of the day, you execute the following procedure:

- Examine each grocery item to determine its type.
- Read the price stored in the compartment corresponding to that type of grocery.
- Add that price to that customer's bill using your mechanical adding machine.

In programming jargon, we would say that as you process each grocery item for the same customer, you are *looping* . We would also say that you are executing a procedure or an *algorithm* .

When you have processed all of the grocery items for a particular customer, you would

- Press the TOTAL key on the adding machine,
- Turn the crank, and
- Present the customer with the bill.

A schematic representation of the procedure

We might represent the procedure in schematic form as shown in Figure 1 (p. 29) .

Figure 1 . A checkout counter algorithm.
<pre> For each customer, do the following: For each item, do the following: a. Identify the type of grocery item b. Get the price from the compartment c. Add the price to accumulated total End loop on grocery items Present customer with a bill End loop on a specific customer </pre>

Table 2.5

Common programming activities

This procedure illustrates the three activities commonly believed to be the fundamental activities of any computer program:

- sequence
- selection
- loop

Sequence

A sequence of operations is illustrated by the three items labeled a, b, and c in Figure 1 (p. 29) because they are executed in sequential order.

Selection

The process of identifying the type of grocery item is often referred to as *selection*. A selection operation is the process of selecting among two or more choices.

Loop

The process of repetitively examining each grocery item and processing it is commonly referred to as a *loop*. In the early days of programming, for a programming language named FORTRAN, this was referred to as a *do loop*.

An algorithm

The entire procedure is often referred to as an *algorithm*.

Modifying stored data

Sometimes during the day, the owner of the grocery store may come to you and say that he is going to increase the price of a can of Beans from 15 cents to 25 cents and asks you to take care of the change in price.

You write 25 on a slip of paper and put it in the compartment labeled Beans, being careful to remove and destroy the slip of paper that was previously in that compartment. For the rest of the day, the new price for Beans will be used in your calculations unless the owner asks you to change it again.

Not a bad analogy

This is a pretty good analogy to how random access memory is actually used by a computer program.

Names versus addresses

As a programmer using a high-level language such as Java, you usually don't have to be concerned about the numeric addresses of the compartments.

You are able to think about them and refer to them in terms of their names. (*Names are easier to remember than numeric addresses*). However, deep inside the computer, these names are cross-referenced to addresses and at the lowest level, the program works with memory addresses instead of names.

Execute an algorithm

A computer program always executes some sort of procedure, which is often called an *algorithm*. The algorithm may be very simple as described in the checkout counter example described above, or it may be very complex as would be the case for a spreadsheet program. As the program executes its algorithm, it uses the random access memory to store and retrieve the data that is needed to execute the algorithm.

Why is it called RAM?

The reason this kind of memory is called *RAM* or *random access memory* is that it can be accessed in any order.

Sequential memory

Some types of memory, such as a magnetic tape, must be accessed in sequential order. This means that to get a piece of data (*the price of beans, for example*) from deep inside the memory, it is necessary to start at the beginning and examine every piece of data until the correct one is found.

Combination random/sequential

Other types of memory, such as disks, provide a combination of sequential and random access. For example, the data on a disk is stored in tracks that form concentric circles on the disk. The tracks can be accessed in random order, but the data within a track must be accessed sequentially starting at a specific point on the track.

Sequential memory isn't very good for use by most computer programs because access to each particular piece of data is quite slow.

2.6.3.4 Sample program

Listing 1 (p. 31) shows a sample Java program that illustrates the use of memory for the storage and retrieval of data.

Listing 1 . Program named Memory01.

```
//File Memory01.java
class Memory01 {
    public static void main(String[] args){
        int beans;
        beans = 25;
        System.out.println(beans);
    }//end main
} //End Memory01 class
```

Table 2.6

Listing 2 (p. 31) shows a batch file that you can use to compile and run this program.

Listing 2 . Batch file for Memory01.

```
echo off
cls

del *.class

javac -cp .; Memory01.java
java -cp .; Memory01

pause
```

Table 2.7

Using the procedure that you learned in the *Getting Started*⁴⁹ module, you should be able to compile and execute this program. When you do, the program should display 25 on your computer screen.

Variables

You will learn in a future lesson that the term *variable* is synonymous with the term *compartment* that I have used for illustration purposes in this lesson.

The important lines of code

The use of memory is illustrated by the three lines of code in Listing 1 (p. 31) that begin with **int** , **beans** , and **System** . We will ignore the other lines in the program in this module and learn about them in future modules.

Declaring a variable

⁴⁹<http://cnx.org/content/m45137/latest/>

A memory compartment (*or variable*) is set aside and given the name **beans** by the line that begins with **int** in Listing 1 (p. 31) .

In programmer jargon, this is referred to as *declaring a variable* . The process of declaring a variable

- causes memory to be set aside to contain a value, and
- causes that chunk of memory to be given a name.

That name can be used later to refer to the value stored in that chunk of memory or variable.

This declaration in Listing 1 (p. 31) specifies that any value stored in the variable must be of type **int** . Basically, this means that the value must be an integer. Beyond that, don't worry about what the *type* means at this point. I will explain the concept of type in detail in a future module.

Storing a value in the variable

A value of 25 is stored in the variable named **beans** by the line in Listing 1 (p. 31) that begins with the word **beans** .

In programmer jargon, this is referred to as *assigning a value to a variable* .

From this point forward, when the code in the program refers to this variable by its name, **beans** , the reference to the variable will be interpreted to mean the value stored there.

Retrieving a value from the variable

The line in Listing 1 (p. 31) that begins with the word **System** reads the value stored in the variable named **beans** by referring to the variable by its name.

This line also causes that value to be displayed on your computer screen. However, at this point, you needn't worry about what causes it to be displayed. You will learn those details in a future module. Just remember that the reference to the variable by its name, **beans** , reads the value stored in the variable.

The remaining details

Don't be concerned at this point about the other details in the program. They are there to make it possible for you to compile and execute the program. You will learn about them in future modules.

2.6.4 Run the program

I encourage you to run the program that I presented in this lesson to confirm that you get the same results. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

2.8.3 Discussion and sample code

2.8.3.1 Introduction

Methods have been used in computer programming since the early days of programming. Methods are often called functions, procedures, subroutines, and various other names.

Calculate the square root

Suppose that your program needs to calculate the square root of a number. Referring back to your high-school algebra book, you could refresh your memory on how to calculate a square root. Then you could construct the algorithm describing that process.

Having the algorithm available, you could write the code to calculate the square root and insert it into your program code. Then you could compile, and run your program. If you did it all correctly, your program should calculate the square root. (*For reasons that will become apparent later, I will refer to the code that you inserted as *in-line code*.*)

Oops, need to do it all over again

Suppose that further on in your program you discover that you need to calculate the square root of another number. And later, you discover that you need to calculate the square root of still another number. Obviously, with a few changes, you could copy your original code and insert it as *in-line code* at each location in your program where you need to calculate the square root of a number.

Is there a better way?

⁵⁷<http://www.oracle.com/technetwork/java/javase/downloads/index.html>

⁵⁸<http://download.oracle.com/javase/7/docs/api/>

However, after doing this a few times, you might start asking if there is a better way. The answer is "*yes, there is a better way.*"

A method provides a better way

The better way is to create a separate program module that has the ability to calculate the square root and make that module available for use as a helper to your main program each time your main program needs to calculate a square root. In Java, this separate program module is called a **method** .

2.8.3.2 Standard methods

The Java programming language contains a large number of methods (*in the class libraries*) that are already available for your use. (*Later, I will illustrate the use of a standard method for calculating the square root of a number.*)

In addition to the standard methods that are already available, if you need a method to perform some function and there is no standard method already available to perform that function, you can write your own method.

2.8.3.3 Passing parameters

Make the method general

Normally, when designing and writing a method such as one that can calculate the square root of a number, it is desirable to write it in such a way that it can calculate the square root of any number (*as opposed to only one specific number*) . This is accomplished through the use of something called *parameters* .

The process of causing a method to be executed is commonly referred to as *calling the method* .

Pass me the number please

When your program calls the square-root method, it will need to tell the method the value for which the square root is needed.

In general, many methods will require that you provide certain kinds of information when you *call* them. The code in the method needs this information to be able to accomplish its purpose.

Passing parameters

This process of providing information to a method when you call it is commonly referred to as *passing parameters* to the method. For the square-root method, you need to pass a parameter whose value is the value of the number for which you need the square root.

2.8.3.4 Returning values

A method will usually

- perform an action
- send back an answer. or
- some combination of the two

Performing an action

An example of a method that performs an action is the standard method named **println** . We used the **println** method in an earlier module to cause information to be displayed on the computer screen. This method does not need to send back an answer, because that is not the objective of the method. The objective is simply to display some information.

Sending back an answer

On the other hand, a method that is designed to calculate the square root of a number needs to be able to send the square-root value back to the program that called the method. After all, it wouldn't be very useful if the method calculated the square root and then kept it a secret. The process of sending back an answer is commonly referred to as *returning a value* .

Returned values can be ignored

Methods can be designed in such a way that they either will or will not return a value. When a method does return a value, the program that called the method can either pay attention to that value and use it for some purpose, or ignore it entirely.

For example, in some cases where a method performs an action and also returns a value, the calling program may elect to ignore the returned value. On the other hand, if the sole purpose of a method is to return a value, it wouldn't make much sense for a program to call that method and then ignore the value that is returned (*although that would be technically possible*).

2.8.3.5 Writing your own methods

As mentioned earlier, you can write your own methods in Java. I mention this here so you will know that it is possible. I will have more to say about writing your own methods in future modules.

2.8.3.6 Sample program

A complete listing of a sample program named **SqRt01.java** is provided in Listing 5 (p. 45) near the end of the lesson. A batch file that you can use to compile and run the program is provided in Listing 6 (p. 46).

When you compile and run the program, the following output should appear on your computer screen:

```
5.049752469181039
6.0
```

As you will see shortly, these are the square root values respectively for 25.5 and 36.

2.8.3.6.1 Interesting code fragments

I will explain portions of this program in fragments. I will explain only those portions of the program that are germane to this module. Don't worry about the other details of the program. You will learn about those details in future modules.

You may find it useful to open this lesson in another browser window so that you can easily scroll back and forth among the fragments while reading the discussion.

The first code fragment that I will explain is shown in Listing 1 (p. 42).

Listing 1 . The price of beans.
<pre>double beans; beans = 25.5;</pre>

Table 2.8

What is the price of beans?

The code fragment shown in Listing 1 (p. 42) declares a *variable* named **beans** and assigns a value of 25.5 to the variable. (*I briefly discussed the declaration of variables in a previous module. I will discuss them in more detail in a future module.*)

What is that double thing?

In an earlier module, I declared a variable with a type named **int**. At that time, I explained that only integer values could be stored in that variable.

The variable named **beans** in Listing 1 (p. 42) is declared to be of the type **double**. I will explain the concept of data types in detail in a future module. Briefly, **double** means that you can store any

numeric value in this variable, with or without a decimal part. In other words, you can store a value of 3 or a value of 3.33 in this variable, whereas a variable with a declared type of `int` won't accept a value of 3.33.

Every method has a name

Every method, every variable, and some other things as well have names. The names in Java are *case sensitive*. By case sensitive, I mean that the method named `amethod` is not the same as the method named `aMethod`.

A few words about names in Java

There are several rules that define the format of allowable names in Java. You can dig into this in more detail on the web if you like, but if you follow these two rules, you will be okay:

- Use only letters and numbers in Java names.
- Always make the first character a letter.

A standard method named `sqrt`

Java provides a `Math` library that contains many standard methods. Included in those methods is a method named `sqrt` that will calculate and return the square root of a number that is passed as a parameter when the method is called.

The `sqrt` method is called on the right-hand side of the equal sign (=) in the code fragment in Listing 2 (p. 43).

Listing 2 . Compute the square root of the price of beans.

```
double sqRtBns = Math.sqrt(beans);
```

Table 2.9

Calling the `sqrt` method

I'm not sure why you would want to do this, but the code fragment in Listing 2 (p. 43)

- calls the `sqrt` method and
- passes a copy of the value stored in the `beans` variable as a parameter.

The `sqrt` method calculates and returns the square root of the number that it receives as its incoming parameter. In this case, it returns the square root of the price of a can of beans.

A place to save the square root

I needed some place to save the square root value until I could display it on the computer screen later in the program. I declared another variable named `sqRtBns` in the code fragment in Listing 2 (p. 43). I also caused the value returned from the `sqrt` method to be stored in, or assigned to, this new variable named `sqRtBns`.

How should we interpret this code fragment?

You can think of the process implemented by the code fragment in Listing 2 (p. 43) as follows.

First note that there is an equal sign (=) near the center of the line of code. (*Later we will learn that this is called the assignment operator.*)

The code on the left-hand side of the assignment operator causes a new chunk of memory to be set aside and named `sqRtBns`. (*We call this chunk of code a variable.*)

The code on the right-hand side of the assignment operator calls the `sqrt` method, passing a copy of the value stored in the `beans` variable to the method.

When the `sqrt` method returns the value that is the square root of its incoming parameter, the assignment operator causes that value to be stored and saved in (*assigned to*) the variable named `sqRtBns`.

Now display the square root value

The code in the fragment in Listing 3 (p. 44) causes the value now stored in `sqRtBns` to be displayed on the computer screen.

Listing 3 . Display the square root value.

```
System.out.println(sqRtBns);
```

Table 2.10**Another method is called here**

The display of the square root value is accomplished by

- calling another standard method named `println` and
- passing a copy of the value stored in `sqRtBns` as a parameter to the method.

The `println` method performs an action (*displaying something on the computer screen*) and doesn't return a value.

A method exhibits behavior

We say that a method exhibits behavior. The behavior of the `sqrt` method is to calculate and return the square root of the value passed to it as a parameter.

The behavior of the `println` method is to cause its incoming parameter to be displayed on the computer screen.

What do we mean by syntax?

Syntax is a word that is often used in computer programming. The thesaurus in the editor that I am using to type this document says that a synonym for syntax is grammar.

I also like to think of syntax as meaning something very similar to format.

Syntax for passing parameters

Note the syntax in Listing 2 (p. 43) and Listing 3 (p. 44) for passing a parameter to the method. The syntax consists of following the name of the method with a pair of matching parentheses that contain the parameter. If more than one parameter is being passed, they are all included within the parentheses and separated by commas. Usually, the order of the parameters is important if more than one parameter is being passed.

Reusing the methods

The purpose of the code fragment in Listing 4 (p. 44) is to illustrate the reusable nature of methods.

Listing 4 . Calling the same methods again.

```
double peas;
peas = 36.;
double sqRtPeas = Math.sqrt(peas);
System.out.println(sqRtPeas);
```

Table 2.11

The code in this fragment calls the same `sqrt` method that was called before. In this case, the method is called to calculate the square root of the value stored in the variable named `peas` instead of the value stored in the variable named `beans` .

This fragment saves the value returned from the `sqrt` method in a new variable named `sqRtPeas` . Then the fragment calls the same `println` method as before to display the value now stored in the variable named `sqRtPeas` .

Write once and use over and over

Methods make it possible to write some code once and then use that code many times in the same program. This is the opposite of *in-line code* , which requires you to write essentially the same code multiple times in order to accomplish the same purpose more than once in a program.

2.8.4 Run the program

I encourage you to run the program that I presented in this lesson to confirm that you get the same results. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

2.8.5 Complete program listings

Listing 5 (p. 45) is a complete listing of the program named `SqRt01` .

Listing 5 . The program named SqRt01.

```
//File SqRt01.java
class SqRt01 {
    public static void main(String[] args){
        double beans;
        beans = 25.5;
        double sqRtBns = Math.sqrt(beans);
        System.out.println(sqRtBns);
        double peas;
        peas = 36.;
        double sqRtPeas = Math.sqrt(peas);
        System.out.println(sqRtPeas);
    }//end main
} //End SqRt01 class
```

2.10.3 Discussion and sample code

2.10.3.1 Comments

Producing and using a Java program consists of the following steps:

1. Write the source code.
2. Compile the source code.
3. Execute the program.

The source code consists of a set of instructions that will later be presented to a special program called a compiler for the purpose of producing a program that can be executed. In other words, when you write the source code, you are writing instructions that the compiler will use to produce the executable program.

Some things should be ignored

Sometimes, when you are writing source code, you would like to include information that may be useful to you, but should be ignored by the compiler. Information of that sort is called a **comment** .

Three styles of comments

Java supports the three styles of comments shown in Figure 1 (p. 54) .

Figure 1 . Three styles of comments.

```
/** special documentation comment
used by the javadoc tool */

/* This is a
multi-line comment */

//Single-line comment
program code // Another single-line comment
```

Table 2.14

The javadoc tool

The javadoc tool mentioned in Figure 1 (p. 54) is a special program that is used to produce documentation for Java programs. Comments of this style begin with `/**` and end with `*/` as shown in Figure 1 (p. 54) .

The compiler ignores everything in the source code that begins and ends with this pattern of characters. Documentation produced using the javadoc program is very useful for on-line or on-screen documentation.

Multi-line comments

Multi-line comments begin with `/*` and end with `*/` as shown in Figure 1 (p. 54) . As you have probably already guessed, the compiler also ignores everything in the source code that matches this format. (A *javadoc comment is simply a multi-line comment insofar as the compiler knows. Only the special program named javadoc.exe cares about javadoc comments.*)

The multi-line comment style is particularly useful for creating large blocks of information that should be ignored by the compiler. This style can be used to produce a comment consisting of a single line of text as well. However, the single-line comment style discussed in the next section requires less typing.

Single-line comments

Single-line comments begin with `//` and end at the end of the line. The compiler ignores the `//` and everything following the slash characters to the end of the line.

This style is particularly useful for inserting short comments throughout the source code. In this case, the `//` can appear at the beginning of the line as shown in Figure 1 (p. 54) , or can appear anywhere in the line, including at the end of some valid source code (also shown in Figure 1 (p. 54) (p. 54)) .

2.10.3.2 Sample program

The purpose of the program named **Comments01** , which is shown in Listing 3 (p. 56) near the end of the module, is to illustrate the use of single and multi-line comments. The program does not contain any javadoc comments.

The commands for a batch file that you can use to compile and run this program are provided in Listing 4 (p. 57) .

When you compile and run the program, the following text should appear on your command-line screen:

```
Hello World
```

2.10.3.2.1 Interesting code fragments

I will explain this program in fragments, and will explain only those portions of the program that are germane to this module. Don't worry about the other details of the program at this time. You will learn about those details in future modules.

A multi-line comment

Listing 1 (p. 55) , shows a multi-line comment, which consists of three lines of text.

As required, this multi-line comment begins with `/*` and ends with `*/`. The extra stars on the third line are simply part of the comment.

You will often see formats similar to this being used to provide a visual separation between multi-line comments and the other parts of a program.

Listing 1 . A multi-line comment.

```
/*File Comments01.java
This is a multi-line comment.
******/
```

Table 2.15

Single-line comments

Listing 2 (p. 56) shows three single-line comments. Can you spot them? Remember, single-line comments begin with `//`.

Listing 2 . Three single-line comments.

```

class Comments01 {
  //This is a single-line comment
  public static void main(String[] args){
    System.out.println("Hello World");
  }//end main
} //End class

```

Table 2.16

One of the comments in Listing 2 (p. 56) starts at the beginning of the line. The other two comments follow some program code.

2.10.4 Run the program

I encourage you to run the program that I presented in this lesson to confirm that you get the same results. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

2.10.5 Complete program listings

Listing 3 (p. 56) contains a complete listing of the program named **Comments01** .

Listing 3 . The program named Comments01.

```

/*File Comments01.java
This is a multi-line comment.

  //This is a single-line comment

    System.out.println("Hello World");
  }//end main
} //End class

2.12.3 Discussion

2.12.3.1 Introduction

Type-sensitive languages

Java and some other modern programming languages make heavy use of a concept that we refer to as *type* , or *data type* .

We refer to those languages as *type-sensitive languages* . Not all languages are type-sensitive languages. In particular, some languages hide the concept of type from the programmer and automatically deal with type issues behind the scenes.

So, what do we mean by type?

One analogy that comes to my mind is international currency. For example, many years ago, I spent a little time in Japan and quite a long time on an island named Okinawa (*Okinawa is now part of Japan*) .

Types of currency

At that time, as now, the type of currency used in the United States was the dollar. The type of currency used in Japan was the yen, and the type of currency used on the island of Okinawa was also the yen. However, even though two of the currencies had the same name, they were different types of currency, as determined by the value relationships among them.

The exchange rate

As I recall, at that time, the exchange rate between the Japanese yen and the U.S. dollar was 360 yen for each dollar. The exchange rate between the Okinawan yen and the U.S. dollar was 120 yen for each dollar. This suggests that the exchange rate between the Japanese yen and the Okinawan yen would have been 3 Japanese yen for each Okinawan yen.

Analogous to different types of data

So, why am I telling you this? I am telling you this to illustrate the concept that different types of currency are roughly analogous to different data types in programming.

Purchasing transactions were type sensitive

In particular, because there were three different types of currency involved, the differences in the types had to be taken into account in any purchasing transaction to determine the price in that particular currency. In other words, the purchasing process was sensitive to the type of currency being used for the purchase (*type sensitive*) .

Different types of data

Type-sensitive programming languages deal with different types of data. Some data types such as type **int** involve whole numbers only (*no fractional parts are allowed*) .

Other data types such as **double** involve numbers with fractional parts.

Some data types conceptually have nothing to do with numeric values, but deal only with the concept of true or false (*boolean*) or with the concept of the letters of the alphabet and the punctuation characters (*char*) .

Type specification

For every different type of data used with a particular programming language, there is a specification somewhere that defines two important characteristics of the type:

1. What is the set of all possible data values that can be stored in an instance of the type (we will learn some other names for instance later) ?
2. Once you have an instance of the type, what are the operations that you can perform on that instance alone, or in combination with other instances?

What do I mean by an instance of a type?

Think of the type specification as being analogous to the plan or blueprint for a model airplane. Assume that you build three model airplanes from the same set of plans. You will have created three *instances* of the plans.

We might say that an *instance* is the physical manifestation of a plan or a type.

Using mixed types

Somewhat secondary to the specifications for the different types, but also extremely important, is a set of rules that define what happens when you perform an operation involving mixed types (such as making a purchase using some yen currency in combination with some dollar currency) .

The short data type

For example, in addition to the integer type *int* , there is a data type in Java known as *short* . The *short* type is also an integer type.

If you have an instance of the *short* type, the set of all possible values that you can store in that instance is the set of all the whole numbers ranging from -32,768 to +32,767.

This constitutes a set of 65,536 different values, including the value zero. No other value can be stored in an instance of the type *short* . For example, you cannot store the value 35,000 in an instance of the type *short* in Java. If you need to store that value, you will need to use some type other than *short* .

Kind of like an odometer

This is somewhat analogous to the odometer in your car (the thing that records how many miles the car has been driven) . For example, depending on the make and model of car, there is a specified set of values that can appear in the odometer. The value that appears in the odometer depends on how many miles your car has been driven.

It is fairly common for an odometer to be able to store and to display the set of all positive values ranging from zero to 99999. If your odometer is designed to store that set of values and if you drive your car more than 99999 miles, it is likely that the odometer will roll over and start back at zero after you pass the 99999-mile mark. In other words, that particular odometer does not have the ability to store a value of 100,000 miles. Once you pass the 99999-mark, the data stored in the odometer is corrupt.

Now let's return to the Java type named short

Assume that you have two instances of the type *short* in a Java program. What are the operations that you can perform on those instances? For example:

- You can add them together.
- You can subtract one from the other.
- You can multiply one by the other.
- You can divide one by the other.
- You can compare one with the other to determine which is algebraically larger.

There are some other operations that are allowed as well. In fact, there is a well-defined set of operations that you are allowed to perform on those instances. That set of operations is defined in the specification for the type *short* .

What if you want to do something different?

However, if you want to perform an operation that is not allowed by the type specification, then you will have to find another way to accomplish that purpose.

For example, some programming languages allow you to raise whole-number types to a power (*examples: four squared, six cubed, nine to the fourth power, etc.*) . However, that operation is not allowed by the Java specification for the type `short` . If you need to do that operation with a data value of the Java `short` type, you must find another way to do it.

Two major categories of type

Java data types can be subdivided into two major categories:

- Primitive types
- User-defined or reference types

These categories are discussed in more detail in the following sections.

2.12.3.2 Primitive types

Java is an extensible programming language

What this means is that there is a core component to the language that is always available. Beyond this, individual programmers can extend the language to provide new capabilities. The primitive types discussed in this section are the types that are part of the core language. A later section will discuss user-defined types that become available when a programmer extends the language.

More subdivision

It seems that when teaching programming, I constantly find myself subdividing topics into sub-topics. I am going to subdivide the topic of Primitive Types into four categories:

- Whole-number types
- Floating-point types
- Character types
- Boolean types

Hopefully this categorization will make it possible for me to explain these types in a way that is easier for you to understand.

2.12.3.2.1 Whole-number types

The whole-number types, often called *integer* types, are relatively easy to understand. These are types that can be used to represent data without fractional parts.

Applesauce and hamburger

For example, consider purchasing applesauce and hamburger. At the grocery store where I shop, I am allowed to purchase cans of applesauce only in whole-number or integer quantities.

Can purchase integer quantities only

For example, the grocer is happy to sell me one can of applesauce and is even happier to sell me 36 cans of applesauce. However, she would be very unhappy if I were to open a can of applesauce in the store and attempt to purchase 6.3 cans of applesauce.

Counting doesn't require fractional parts

A count of the number of cans of applesauce that I purchase is somewhat analogous to the concept of whole-number data types in Java. Applesauce is not available in fractional parts of cans (*at my grocery store*) .

Fractional pounds of hamburger are available

On the other hand, the grocer is perfectly willing to sell me 6.3 pounds of hamburger. This is somewhat analogous to *floating-point data types* in Java.

Accommodating applesauce and hamburger in a program

Therefore, if I were writing a program dealing with quantities of applesauce and hamburger, I might elect to use a whole number type to represent cans of applesauce and to use a floating-point type to represent pounds of hamburger.

Different whole-number types

In Java, there are four different whole-number types:

- byte
- short
- int
- long

(The char type is also a whole number type, but since it is not intended to be used for arithmetic, I discuss it later as a character type.)

The four types differ primarily in terms of the range of values that they can accommodate and the amount of computer memory required to store instances of the types.

Differences in operations?

Although there are some subtle differences among the four whole-number types in terms of the operations that you can perform on them, I will defer a discussion of those differences until a more advanced module.

*(For example some operations require instances of the **byte** and **short** types to be converted to type **int** before the operation takes place.)*

Algebraically signed values

All four of these types can be used to represent algebraically signed values ranging from a specific negative value to a specific positive value.

Range of the byte type

For example, the **byte** type can be used to represent the set of whole numbers ranging from -128 to +127 inclusive. *(This constitutes a set of 256 different values, including the value zero.)*

The **byte** type cannot be used to represent any value outside this range. For example, the **byte** type cannot be used to represent either -129 or +128.

No fractional parts allowed by the byte type

Also, the **byte** type cannot be used to represent fractional values within the allowable range. For example, the byte type cannot be used to represent the value of 63.5 or any other value that has a fractional part.

Like a strange odometer

To form a crude analogy, the byte type is sort of like a strange odometer in a new *(and unusual)* car that shows a mileage value of -128 when you first purchase the car. As you drive the car, the negative values shown on the odometer increment toward zero and then pass zero. Beyond that point they increment up toward the value of +127.

Oops, numeric overflow!

When the value passes *(or attempts to pass)* +127 miles, something bad happens. From that point forward, the value shown on the odometer is not a reliable indicator of the number of miles that the car has been driven.

Ranges for each of the whole-number types

Figure 1 (p. 66) shows the range of values that can be accommodated by each of the four whole-number types supported by the Java programming language:

Figure 1 . Range of values for whole-number types.

continued on next page

byte	-128 to +127
short	-32768 to +32767
int	-2147483648 to +2147483647
long	-9223372036854775808 to +9223372036854775807

Table 2.19

Can represent some fairly large values

As you can see, the **int** and **long** types can represent some fairly large values. However, if your task involves calculations such as distances in interstellar space, these ranges probably won't accommodate your needs. This will lead you to consider using the *floating-point* types discussed in the upcoming sections. I will discuss the operations that can be performed on whole-number types more fully in future modules.

2.12.3.2.2 Floating-point types

Floating-point types are a little more complicated than whole-number types. I found the definition of floating-point shown in Figure 2 (p. 67) in the *Free On-Line Dictionary of Computing* at this URL ⁷⁷.

Figure 2 . Definition of floating point.

A number representation consisting of a mantissa, M, an exponent, E, and an (assumed) radix (or "base") . The number

Table 2.20

So what does this really mean?

Assuming a base or radix of 10, I will attempt to explain it using an example.

Consider the following value:

623.57185

I can represent this value in any of the ways shown in Figure 3 (p. 68) (where * indicates multiplication).

⁷⁷<http://foldoc.org/floating+point>

Figure 3 . Different ways to represent 623.57185.

```
.62357185*1000
6.2357185*100
62.357185*10
623.57185*1
6235.7185*0.1
62357.185*0.01
623571.85*0.001
6235718.5*0.0001
62357185.*0.00001
```

Table 2.21

In other words, I can represent the value as a mantissa (62357185) multiplied by a factor where the purpose of the factor is to represent a left or right shift in the position of the decimal point.

Now consider the factor

Each of the factors shown in Figure 3 (p. 68) represents the value of ten raised to some specific power, such as ten squared, ten cubed, ten raised to the fourth power, etc.

Exponentiation

If we allow the following symbol (^) to represent exponentiation (*raising to a power*) and allow the following symbol (/) to represent division, then we can write the values for the above factors in the ways shown in Figure 4 (p. 68) .

Note in particular the characters following the first equal character (=) on each line, which I will refer to later as the exponents.

Figure 4 . Relationships between multiplicative factors and exponentiation.

```
1000 = 10^+3 = 1*10*10*10
100 = 10^+2 = 1*10*10
10 = 10^+1 = 1*10
1 = 10^+0 = 1
0.1 = 10^-1 = 1/10
0.01 = 10^-2 = 1/(10*10)
0.001 = 10^-3 = 1/(10*10*10)
0.0001 = 10^-4 = 1/(10*10*10*10)
0.00001 = 10^-5 = 1/(10*10*10*10*10)
```

Table 2.22

In the above notation, the term 10^{+3} means 10 raised to the third power.

The zeroth power

By definition, the value of any value raised to the zeroth power is 1. (*Check this out in your high-school algebra book.*)

The exponent and the factor

Hopefully, at this point you will understand the relationship between the exponent and the factor introduced earlier in Figure 3 (p. 68) .

Different ways to represent the same value

Having reached this point, by using substitution, I can rewrite the original set of representations (p. 68) of the value 623.57185 in the ways shown in Figure 5 (p. 69) .

(It is very important to for you to understand that these are simply different ways to represent the same value.)

Figure 5 . Other ways to represent the same information.
$.62357185 \times 10^{+3}$ $6.2357185 \times 10^{+2}$ $62.357185 \times 10^{+1}$ $623.57185 \times 10^{+0}$ 6235.7185×10^{-1} 62357.185×10^{-2} 623571.85×10^{-3} 6235718.5×10^{-4} $62357185. \times 10^{-5}$

Table 2.23

A simple change in notation

Finally, by making a simplifying change in notation where I replace ($\times 10^{\wedge}$) by (E) I can rewrite the different representations of the value of 623.57185 in the ways shown in Figure 6 (p. 69) .

Figure 6 . Still other ways to represent 623.57185.
$.62357185E+3$ $6.2357185E+2$ $62.357185E+1$ $623.57185E+0$ $6235.7185E-1$ $62357.185E-2$ $623571.85E-3$ $6235718.5E-4$ $62357185.E-5$

Table 2.24

Getting the true value

Floating point types represent values as a mantissa containing a decimal point along with an exponent value which tells how many places to shift the decimal point to the left or to the right in order to determine the true value.

Positive exponent values mean that the decimal point should be shifted to the right. Negative exponent values mean that the decimal point should be shifted to the left.

Maintaining fractional parts

One advantage of floating-point types is that they can be used to maintain fractional parts in data values, such as 6.3 pounds of hamburger.

Accommodating a very large range of values

Another advantage is that a very large range of values can be represented using a reasonably small amount of computer memory for storage of the values.

Another example

For example (assuming that I counted the number of digits correctly) the following very large value

62357185000.0

can be represented as

6.2357185E+37

Similarly, again assuming that I counted the digits correctly, the following very small value

0.00062357185

can be represented as

6.2357185E-30

When would you use floating-point?

If you happen to be working in an area where you

- need to keep track of fractional parts (such as the amount of hamburger in a package) ,
- have to work with extremely large numbers (distances between galaxies) , or
- have to work with extremely small values (the size of atomic particles) ,

then you will need to use the floating-point types.

Don't use floating-point in financial transactions

You probably don't want to use floating-point in financial calculations, however, because there is a lot of rounding that takes place in floating-point calculations. In other words, floating point calculations provide answers that are very close to the truth but the answers are often not exact.

Two floating-point types

Java supports two different floating point types:

- float
- double

These two types differ primarily in terms of the range of values that they can support.

Range of values for floating point types

The table in **Figure 7 (p. 70)** (p. 70) shows the smallest and largest values that can be accommodated by each of the floating-point types. Values of either type can be either positive or negative.

Figure 7 . Range of values for floating-point types.	
float	1.4E-45 to 3.4028235E38
double	4.9E-324 to 1.7976931348623157E308

Table 2.25

I will discuss the operations that can be performed on floating-point types in a future module.

2.12.3.2.3 The character type

Computers deal only in numeric values. They don't know how to deal directly with the letters of the alphabet and punctuation characters. This gives rise to a type named `char` .

Purpose of the char type

The purpose of the character type is to make it possible to represent the letters of the alphabet, the punctuation characters, and the numeric characters internally in the computer. This is accomplished by assigning a numeric value to each character, much as you may have done to create secret codes when you were a child.

A single character type

Java supports a single character type named `char` . The char type uses a standard character representation known as **Unicode** to represent up to 65,535 different characters.

Why so many characters?

The reason for the large number of possible characters is to make it possible to represent the characters making up the alphabets of many different countries and many different spoken languages.

What are the numeric values representing characters?

As long as the characters that you use in your program appear on your keyboard, you usually don't have a need to know the numeric value associated with the different characters. If you are curious, however, the upper-case A is represented by the value 65 in the Unicode character set.

Representing a character symbolically

In Java, you usually represent a character in your program by surrounding it with apostrophes as shown below:

```
'A'
```

The Java programming tools know how to cross reference that specific character symbol against the Unicode table to obtain the corresponding numeric value. *(A discussion of the use of the `char` type to represent characters that don't appear on your keyboard is beyond the scope of this module.)*

I will discuss the operations that can be performed on the `char` type in a future module.

2.12.3.2.4 The boolean type

The boolean type is the simplest type supported by Java. It can have only two values:

- true
- false

Generally speaking, about the only operations that can be directly applied to an instance of the **boolean** type are to change it from **true** to **false** , and vice versa. However, the **boolean** type can be included in a large number of somewhat higher-level operations.

The **boolean** type is commonly used in some sort of a test to determine what to do next, such as that shown in Figure 8 (p. 71) .

Figure 8 . Example of the use of the boolean type.

```
Perform a test that returns a value of type boolean.
if that value is true,
    do one thing
otherwise (meaning that value is false)
    do a different thing
```

Table 2.26

I will discuss the operations that can be performed on the `boolean` type in more detail in a future module.

2.12.3.3 User-defined or reference types

Extending the language

Java is an *extensible* programming language. By this, I mean that there is a core component to the language that is always available. Beyond the core component, different programmers can extend the language in different ways to meet their individual needs.

Creating new types

One of the ways that individual programmers can extend the language is to create new types. When creating a new type, the programmer must define the set of values that can be stored in an instance of the type as well as the operations that can be performed on instances of the type.

No magic involved

While this might initially seem like magic, once you get to the heart of the matter, it is really pretty straightforward. New types are created by combining instances of primitive types along with instances of other user-defined types. In other words, the process begins with the primitive types explained earlier and builds upward from there.

An example

For example, a `String` type, which can be used to represent a person's last name, is just a grouping of a bunch of instances of the primitive `char` or character type.

A user-defined `Person` type, which could be used to represent both a person's first name and their last name, might simply be a grouping of two instances of the user-defined `String` type. (*The `String` type is part of the Java standard library. However, the standard library doesn't have a type named `Person`. If you need that type, you will have to define it yourself.*)

Differences

The biggest conceptual difference between the `String` type and the `Person` type is that the `String` type is contained in the standard Java library while the `Person` type isn't in that library. However, you could put it in a library of your own design if you choose to do so.

Removing types

You could easily remove the `String` type from your copy of the standard Java library if you choose to do so, although that would probably be a bad idea. However, you cannot remove the primitive `double` type from the core language without making major modifications to the language.

The company telephone book

A programmer responsible for producing the company telephone book might create a new type that can be used to store the first and last names along with the telephone number of an individual. That programmer might choose to give the new type the name `Employee`.

The programmer could create an instance of the `Employee` type to represent each employee in the company, populating each such instance with the name and telephone number for an individual employee. (*At this point, let me sneak a little jargon in and tell you that we will be referring to such instances as objects.*)

A comparison operation

The programmer might define one of the allowable operations for the new `Employee` type to be a comparison between two objects of the new type to determine which is greater in an alphabetical sorting sense. This operation could be used to sort the set of objects representing all of the employees into alphabetical order. The set of sorted objects could then be used to print a new telephone book.

A name-change operation

Another allowable operation that the programmer might define would be the ability to change the name stored in an object representing a particular employee. For example when Suzie Smith marries Tom Jones, she might elect to thereafter be known as

- Suzie Smith

- Suzie Jones,
- Suzie Smith-Jones,
- Suzie Jones-Smith, or
- something entirely different.

In this case, there would be a need to modify the object that represents Suzie in order to reflect her newly-elected surname. (*Or perhaps Tom Jones might elect to thereafter be known as Tom Jones-Smith, in which case it would be necessary to modify the object that represents him.*)

An updated telephone book

The person charged with maintaining the database could

- use the name-changing operation to modify the object and change the name,
- make use of the sorting operation to re-sort the set of objects, and
- print and distribute an updated version of the telephone book.

Many user-defined types already exist

Unlike the primitive types which are predefined in the core language, I am unable to give you much in the way of specific information about user-defined types, simply because they don't exist until a user defines them.

I can tell you, however, that when you obtain the Java programming tools from Sun, you not only receive the core language containing the primitive types, you also receive a large library containing several thousand user-defined types that have already been defined. A large documentation package is available from Sun to help you determine the individual characteristics of these user-defined types.

The most important thing

At this stage in your development as a Java programmer, the most important thing for you to know about user-defined types is that they are possible.

You can define new types. Unlike earlier procedural programming languages such as C and Pascal, you are no longer forced to adapt your problem to the available tools. Rather, you now have the opportunity to extend the tools to make them better suited to solve your problem.

The class definition

The specific mechanism that makes it possible for you to define new types in Java is a mechanism known as the *class definition*.

In Java, whenever you define a new class, you are at the same time defining a new type. Your new type can be as simple, or as complex and powerful as you want it to be.

An object (*instance*) of your new type can contain a very small amount of data, or it can contain a very large amount of data. The operations that you allow to be performed on an object of your new type can be rudimentary, or they can be very powerful.

It is all up to you

Whenever you define a new class (*type*) you not only have the opportunity to define the data definition and the operations, you also have a responsibility to do so.

Much to learn and much to do

But, you still have much to learn and much to do before you will need to define new types.

There are a lot of fundamental programming concepts that we will need to cover before we seriously embark on a study involving the definition of new types.

For the present then, simply remember that such a capability is available, and if you work to expand your knowledge of Java programming one small step at a time, when we reach the point of defining new types, you will be ready and eager to do so.

2.12.3.4 Sample program

I'm not going to provide a sample program in this module. Instead, I will be using what you have learned about Java data types in the sample programs in future modules.

2.14.3 Introduction

This module introduces you to Java programming by presenting and discussing a traditional *Hello World* program.

Two approaches

Java programs can be written and executed in several different ways, including the following:

- Stand-alone application from the command line.
- Applet that runs under control of a Java-capable browser.

It is also possible in many cases to write applets, which can be run in a stand-alone mode from the command line, or can be run under control of a Java-capable browser. An example of such an applet will be presented in a future module.

Applets vs. applications

Programming an *"application"* in Java is significantly different from programming an *"applet."* Applets are designed to be downloaded and executed on-line under control of a browser.

Restrictions on applets

Their functionality of an applet is usually restricted in an attempt to prevent downloaded applets from damaging your computer or your data. No such restrictions apply to the functionality of a Java application.

Class definitions

All Java programs consist of one or more **class** definitions. In this course, I will often refer to the *primary* class definition for a Java *application* as the *controlling class* .

The main method

A stand-alone Java application requires a method named **main** in its *controlling class* .

An **Applet** does not require a **main** method. The reason that a Java **Applet** does not require a **main** method will be explained in a future module.

Getting started

Figure 1 (p. 85) shows the steps for compiling and running a Java application.

Figure 1. How to compile and run a Java application.

Here are the steps for compiling and running a Java application, based on the assumption that you are running under Windows. If you are running under some other operating system, you will need to translate these instructions to that OS.

1. Download and install the JDK from Oracle. Also consider downloading and installing the documentation, which is a separate download.
2. Using any editor that can produce a plain text file (*such as Notepad*), create a source code file with the extension on the file name being `.java`. This file contains your actual Java instructions. (*You can copy some sample programs from the early lessons in this collection to get started.*)
3. Open a command-line window and change directory to the directory containing the source file. It doesn't really matter which directory the source file is in, but I normally put my Java files in a directory all their own.
4. Assume that the name of the file is `joe.java`, just to have something definitive to refer to.
5. To compile the file, enter the following command at the prompt:

```
javac joe.java
```

6. Correct any compiler errors that show up. Once you have corrected all compiler errors, the `javac` program will execute and return immediately to the prompt with no output. At that point, the directory should also contain a file named `joe.class` and possibly some other files with a `.class` extension as well. These are the compiled Java files.
7. To run the program, enter the following command:

```
java joe
```

8. If your program produces the correct output, congratulations. You have written, compiled, and executed a Java application. If not, you will need to determine why not.

Table 2.27

2.14.4 The Java version of Hello World

The class file

Compiled Java programs are stored in "bytecode" form in a file with an extension of `.class` where the name of the file is the same as the name of the *controlling class* (or *other class*) in the program.

The main method is static

The `main` method in the controlling class of an application must be `static`, which results in `main` being a `class` method.

`Class` methods can be called without a requirement to instantiate an object of the class.

When a Java application is started, the *Java Virtual Machine* or *JVM* (an executable file named `java.exe`) finds and calls the `main` method in the class whose name matches the name of the class file specified on the command line.

Running an application

For example, to start the JVM and run a Java application named `hello1`, a command such as the following must be executed at the operating system prompt:

```
java hello1
```

This command instructs the operating system to start the JVM, and then instructs the JVM to find and execute the java application stored in the file named `hello1.class`. (*Note that the `.class` extension is not included in the command.*)

This sample program is a Java application named **hello1.java** .
 When compiled, it produces a class file named **hello1.class** .
 When the program is run, the JVM calls the **main** method defined in the *controlling class* .
 The **main** method is a *class* method.
Class methods can be called without a requirement to instantiate an object of the class.
 The program displays the following words on the screen:

```
Hello World
```

2.14.5 Interesting code fragments

I will explain this program code in fragments. A complete listing of the program is provided in Listing 5 (p. 89) .

The code fragment in Listing 1 (p. 86) shows the first line of the class definition for the controlling class named **hello1** . (*I will discuss class definitions in detail in a future module.*)

Listing 1 . Beginning of the class named hello1.

<pre>class hello1 { //define the controlling class</pre>
--

Table 2.28

The code fragment in Listing 2 (p. 86) begins the definition of the **main** method. I will also discuss method definitions in detail in a future module.

Listing 2 . Beginning of the main method.
--

<pre>public static void main(String[] args){</pre>
--

Table 2.29

The fragment in Listing 3 (p. 86) causes the string **Hello World** to be displayed on the command-line screen.

The statement in Listing 3 (p. 86) is an extremely powerful statement from an object-oriented programming viewpoint. When you understand how it works, you will be well on your way to understanding the Java version of Object-Oriented Programming (OOP).

I will discuss this statement in more detail later in a future module.

Listing 3 . Display the string Hello World.
--

<i>continued on next page</i>

```
System.out.println("Hello World");
```

Table 2.30

Listing 4 (p. 87) ends the **main** method and also ends the class definition for the class named **hello1**

Listing 4 . End of the class named hello1.

```
}//end main
};//End hello1 class
```

Table 2.31

The complete program listing

As mentioned earlier, a complete listing of the program is provided in Listing 5 (p. 89) near the end of the module.

2.14.6 General information

This program illustrates several general aspects of Java programming.

Overall skeleton of java program

The overall skeleton of any Java program consists of one or more class definitions.

All methods and variables must be defined inside a **class** definition. There can be no freestanding methods or global variables.

File names and extensions

The name of the *controlling class* should be the same as the name of the source file that contains it.

Files containing source code in Java have an extension of *java* .

The main method

The controlling class definition for an application must contain the **main** method.

The primary class file

The file produced by compiling the file containing the controlling class has the same name as the controlling class, and has an extension of **class** .

Many class files may be produced

The java compiler produces a separate file for every class definition contained in an application or applet, even if two or more class definitions are contained in the same source file.

Thus, the compilation of a large application can produce many different *class* files.

What are jar files?

A feature known as a *jar* file can be used to consolidate those class files into a single file for more compact storage, distribution, and transmission. Such a file has an extension of **.jar** . (*A jar file is similar to a zip file except that it is specialized for use with Java programs.*)

The main method is static

The controlling class for a Java application must contain a **static** method named **main** .

When you run the application using the JVM, you specify the name of the *class* file that you want to run.

The JVM then calls the **main** method defined in the *class* file having that name. This is possible because a *class method* can be called without a requirement to instantiate an object of the class.

The **main** method defined in that class definition controls the flow of the program.

2.14.7 Run the program

I encourage you to copy the code from Listing 5 (p. 89) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

A complete listing of the program discussed in this module is provided in Listing 5 (p. 89) .

Listing 5 . Complete program listing.

```

/*File hello1.java Copyright 1997, R.G.Baldwin
This is a Java application program .

When compiled, this program produces the class named:

hello1.class

When the Java interpreter is called upon the application's
controlling class using the following statement at the
command line:

java hello1

the interpreter starts the program by calling the main
method defined in the controlling class. The main method is
a class method which can be called without the requirement
to instantiate an object of the class.

The program displays the following words on the screen:

Hello World

*****/
class hello1 { //define the controlling class
  //define main method
  public static void main(String[] args){
    //display text string
    System.out.println("Hello World");
  } //end main
} //End hello1 class.

2.16.4 Introduction

New types

Java makes extensive use of classes. When a class is defined in Java, a new *type* comes into being. The new type definition can then be used to instantiate (*create instances of*) one or more objects of that new type.

A blueprint

The class definition provides a *blueprint* that describes the *data* contained within, and the *behavior* of objects instantiated according to the new type.

The data

The data is contained in variables defined within the class (*often called member variables, data members, attributes, fields, properties, etc.*).

The behavior

The behavior is controlled by methods defined within the class.

State and behavior

An object is said to have *state* and *behavior* . At any instant in time, the *state* of an object is determined by the values stored in its *variables* and its behavior is determined by its *methods* .

Class vs. instance

It is possible to define:

- instance variables and instance methods
- static or *class* variables and static or *class* methods.

Instance variables and instance methods can only be accessed through an object instantiated from the class. They belong to the individual objects, (*which is why they are called instance variables and instance methods*) .

Class variables and *class* methods can be accessed without first instantiating an object. They are shared among all of the objects instantiated from the class and are even accessible in the total absence of an object of the class.

The class name alone is sufficient for accessing *class* variables and *class* methods by joining the name of the class to the name of the variable or method using a period.

2.16.5 Defining a class in Java

The general syntax for defining a class in Java is shown in Listing 1 (p. 97) .

Listing 1 . General syntax for defining a Java class.
<pre>class MyClassName{ . . . } //End of class definition.</pre>

Table 2.36

This syntax defines a class and creates a new type named **MyClassName** .

The definitions of variables, methods, constructors, and a variety of other members are inserted between the opening and closing curly brackets.

 - Viewing tip (p. 103)
 - * Figures (p. 103)

2.18.2 Preface

This module is part of a collection of modules designed to help you learn to program computers.

Every Java application requires a class containing a method named **main**. This module provides information on the **main** method.

2.18.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures while you are reading about them.

2.18.2.1.1 Figures

- Figure 1 (p. 103) . The method signature according to Niemeyer and Peck.
- Figure 2 (p. 105) . The method signature according to Oracle.
- Figure 3 (p. 105) . Allowable signatures for the main method.

2.18.3 The main method in Java

There must be a **main** method in the controlling class in every Java application.

The method signature

The Java literature frequently refers to the signature of a method, or the *method signature*.

Exploring Java by Patrick Niemeyer and Joshua Peck (O'Reilly) provides the definition of a method signature shown in Figure 1 (p. 103).

<p>Figure 1. The method signature according to Niemeyer and Peck .</p>
<p>"A method signature is a collection of information about the method, as in a C prototype or a forward function declaration in other languages. It includes the method's name, type, and visibility, as well as its arguments and return type."</p>

Table 2.37

Type

Apparently in this definition, the authors are referring to the *type* of the method as distinguishing between static and non-static. (*Other literature refers to the type of a function or method as being the return type which according to the above definition is a separate part of the signature.*)

Visibility

Apparently also the use of the word visibility in the above definition refers to the use of **public**, **private**, etc.

According to Oracle...

Oracle's Java Tutorials⁹⁹, on the other hand, describe the method signature as in Figure 2 (p. 105).

⁹⁹<http://docs.oracle.com/javase/tutorial/java/javaOO/methods.html>

Figure 2. The method signature according to Oracle .

Definition: Two of the components of a method declaration comprise the method signature – the method’s name and the parameter types.

Table 2.38

As you can see, the Oracle definition is more restrictive than the Niemeyer and Peck definition.

Bottom line on method signature

The method signature can probably be thought of as providing information about the programming interface to the method. In other words, it provides the information that you need to be able to call the method in your program code.

Signature of main method

The controlling class of every Java application must contain a **main** method having one of the signatures shown in Figure 3 (p. 105) .

Figure 3 . Allowable signatures for the main method.

```
public static void main(String[] args)
public static void main(String args[])
```

Table 2.39

*(I prefer the first signature in Figure 3 (p. 105) (p. 105) as being the most descriptive of an array of **String** references which is what is passed in as an argument.)*

public

The keyword **public** indicates that the method can be called by any object. A future module will discuss the keywords **public** , **private** , and **protected** in more detail.

static

The keyword **static** indicates that the method is a *class* method, which can be called without the requirement to instantiate an object of the class. This is used by the JVM to launch the program by calling the **main** method of the class identified in the command to start the program.

void

The keyword **void** indicates that the method doesn’t return any value.

args

The formal parameter **args** is a reference to an array object of type **String** . The array elements contain references to **String** objects that encapsulate **String** representations of the arguments, if any, entered at the command line.

Note that the **args** parameter must be specified whether or not the user is required to enter command-line arguments and whether or not the code in the program actually makes use of the argument. Also note that the name can be any legal Java identifier. It doesn’t have to be **args** . It could be **joe** or **sue**, for example.

The length property

The parameter named **args** is a reference to an array object. Java array objects have a property named **length** , which specifies the number of elements in the array.

The runtime system monitors for the entry of command-line arguments by the user and constructs the **String** array containing those arguments.

Processing command-line arguments

The **args.length** property can be used by the code in the program to determine the number of arguments actually entered by the user.

If the **length** property is not equal to zero, the first string in the array corresponds to the first argument entered on the command line.

Command-line arguments along with strings and **String** arrays will be discussed in more detail in a future module.

2.19.3.5 Question 5

True or false? If the Java application is not designed to use command-line arguments, it is not necessary to include a formal parameter for the **main** method.

Answer 5 (p. 110)

2.19.3.6 Question 6

True or false? When using command-line arguments in Java, if the name of the string array is **args** , the **args.length** variable can be used by the code in the program to determine the number of arguments actually entered.

Answer 6 (p. 110)

2.19.3.7 Question 7

True or false? The first string in the array of command-line arguments contains the name of the Java application

Answer 7 (p. 110)

2.19.3.8 Question 8

The *controlling class* of every Java application must contain a **main** method. Can other classes in the same application also have a **main** method? If not, why not? If so, why might you want to do that?

Answer 8 (p. 110)

What is the meaning of the following two images?

This image was inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

The image is also an example of the kinds of things that we do in my course titled ITSE 2321, Object-Oriented Programming.

This image was also inserted for the purpose of inserting space between the questions and the answers.

2.19.4 Answers

2.19.4.1 Answer 8

Any and all classes in a Java application can have a **main** method. Only the one in the *controlling class* for the program being executed is actually called.

It is often desirable to provide a **main** method for a class that will not ultimately be the *controlling class* to allow the class to be tested in a stand-alone mode, independent of other classes.

Back to Question 8 (p. 108)

2.19.4.2 Answer 7

False. Unlike C++, the first string in the array of command-line arguments in a Java application does **not** contain the name of the application.

Back to Question 7 (p. 108)

2.19.4.3 Answer 6

True.

Back to Question 6 (p. 108)

2.19.4.4 Answer 5

False. The **main** method in a Java program must always provide the formal argument list regardless of whether it is actually used in the program.

Back to Question 5 (p. 108)

2.19.4.5 Answer 4

The **void** keyword when used as the return type for any Java method indicates that the method does not **return** anything.

Back to Question 4 (p. 107)

2.19.4.6 Answer 3

The keyword **static** indicates that the method is a *class* method which can be called without the requirement to instantiate an object of the class. This is used by the Java virtual machine to launch the program by calling the **main** method of the class identified in the command to start the program.

Back to Question 3 (p. 107)

2.19.4.7 Answer 2

The keyword **public** indicates that the method can be called by any object.

Back to Question 2 (p. 107)

2.19.4.8 Answer 1

```
public static void main(String[] args)
```

2.20.2 Preface

This module takes a preliminary look at the complexity of OOP by examining some aspects of the **System** and **PrintStream** classes.

2.20.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the listings while you are reading about them.

2.20.2.1.1 Listings

- Listing 1 (p. 112) . The program named `hello1`.
- Listing 2 (p. 113) . Display the string "Hello World".

2.20.3 Introduction

This lesson introduces you to the use of the **System** and **PrintStream** classes in Java. This is our first introduction to the complexity that can accompany the **OOP** paradigm. It gets a little complicated, so you might need to pay special attention to the discussion.

2.20.4 Discussion

What does the main method do?

The **main** method in the controlling class of a Java application controls the flow of the program.

The **main** method can also access other classes along with the variables and methods of those classes and of objects instantiated from those classes.

The `hello1` Application

Listing 1 (p. 112) shows a simple Java application named **hello1** .

(By convention, class definitions should begin with an upper-case character. However, the original version of this module was written and published in 1997, before that convention was firmly established.)

Listing 1 . The program named `hello1`.

```
/*File hello1.java Copyright 1997, R.G.Baldwin
*****
class hello1 { //define the controlling class
    //define main method
    public static void main(String[] args){
        //display text string
        System.out.println("Hello World");
    }//end main
} //End hello1 class. No semicolon at end of Java class.
```

Table 2.40

Does this program instantiate objects?

This is a simple example that does not instantiate objects of any other class.

Does this program access another class?

However, it does access another class. It accesses the **System** class that is provided with the Java development kit. (*The **System** class will be discussed in more detail in a future module.*)

The variable named **out**

The variable named **out**, referred to in Listing 1 (p. 112) as **System.out**, is a *class variable* of the **System** class. (*A class variable is a variable that is declared to be static.*)

Recall that a class variable can be accessed without a requirement to instantiate an object of the class. As is the case with all variables, the class variable must be of some specific type.

Primitive variables vs. reference variables

A class variable may be a *primitive variable*, which contains a primitive value, or it may be a *reference variable*, which contains a reference to an object.

(*I'll have more to say about the difference between primitive variables and reference variables in a future module.*)

The variable named **out** in this case is a *reference variable*, which refers to an object of another type.

Accessing class variables

You access class variables or class methods in Java by joining the name of the class to the name of the variable or method with a period as shown below.

```
System.out
```

accesses the class variable named **out** in the Java class named **System**.

The **PrintStream** class

Another class that is provided with the Java development kit is the **PrintStream** class. The **PrintStream** class is in a package of classes that are used to provide stream input/output capability for Java.

What does the **out** variable refer to?

The **out** variable in the **System** class refers to (*points to*) an instance of the **PrintStream** class (a ***PrintStream** object*), which is automatically instantiated when the **System** class is loaded into the application.

We will be discussing the **PrintStream** class along with a number of other classes in detail in a future module on input/output streams, so this is not intended to be an exhaustive discussion.

The **println** method

The **PrintStream** class has an *instance method* named **println**, which causes its argument to be displayed on the standard output device when it is called.

(*Typically, the standard output device is the command-line window. However, it is possible to redirect it to some other device.*)

Accessing an instance method

The method named **println** can be accessed by joining a **PrintStream** object's reference to the name of the method using a period.

Thus, (*assuming that the standard output device has not been redirected*), the statement shown in Listing 2 (p. 113) causes the string "Hello World" (*without the quotation marks*) to be displayed in the command-line window.

Listing 2 . Display the string "Hello World".

```
System.out.println("Hello World");
```

Table 2.41

This statement calls the `println` method of an object instantiated from the `PrintStream` class, which is referred to (*pointed to*) by the variable named `out`, which is a *class variable* of the `System` class.

Read the previous paragraph very carefully. As I indicated when I started this module, this is our first introduction to the complexity that can result from use of the OOP paradigm. (*It can get even more complicated.*) If this is not clear to you, go back over it and think about it until it becomes clear.

2.20.5 A word about class variables

How many instances of a class variable exist?

The runtime system allocates a class variable only once no matter how many instances (*objects*) of the class are instantiated.

All objects of the class share the same physical memory space for the class variable.

If a method in one object changes the value stored in the class variable, it is changed insofar as all of the objects are concerned. (*This is about as close to a global variable as you can get in Java.*)

Accessing a class variable

You can use the name of the class to access class variables by joining the name of the class to the name of the variable using a period.

You can also access a class variable by joining the name of a reference variable containing an object's reference to the name of the variable using a period as the joining operator.

Referencing object methods via class variables

Class variables are either primitive variables or reference variables. (*Primitive variables contain primitive values and reference variables contain references to objects.*)

A referenced object may provide methods to control the behavior of the object. In Listing 2 (p. 113), we accessed the `println` method of an object of the `PrintStream` class referred to by the class variable named `out`.

Instance variables and methods

As a side note, in addition to class variables, Java provides *instance variables* and *instance methods*. Every instance of a class has its own set of instance variables. You can only access instance variables and instance methods through an object of the class.

2.20.6 Run the program

I encourage you to copy the code from Listing 1 (p. 112). Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

2.20.7 Miscellaneous

2.21.4 Answers

2.21.4.1 Answer 18

Every instance of a class has its own set of instance variables. You can only access *instance variables* and *instance methods* through an object of the class. In this case, forty bytes of memory would be required to contain the instance variables of the ten objects.

Back to Question 18 (p. 118)

2.21.4.2 Answer 17

Only one, because `out` is a class variable of the `System` class.

Back to Question 17 (p. 118)

2.21.4.3 Answer 16

The runtime system allocates a *class variable* only once no matter how many instances of the class are instantiated. Thus, all objects of the class share the same physical memory space for the class variable, and in this case, only four bytes of memory will be allocated to contain the allocated variables.

True.

False. The **System** class has several *class* variables (*including out and in*) that are useful without the requirement to instantiate an object of the **System** class.

Back to Question 4 (p. 117)

2.21.4.16 Answer 3

False. While it is probably true that the **main** method must instantiate objects of other classes in order to accomplish much that is of value, this is not a requirement. The **main** method in the "Hello World" program of this module ¹¹¹ does not instantiate objects of any class at all.

Back to Question 3 (p. 116)

2.21.4.17 Answer 2

False. The **main** method can access the variables and methods of objects instantiated from other classes. Otherwise, the flow of the program would be stuck within the **main** method itself and wouldn't be very useful.

2.22.3 Introduction

The first step

The first step in learning to use a new programming language is usually to learn the foundation concepts such as

- variables
- types

- expressions
- flow-of-control, etc.

This and several future modules concentrate on that foundation.

A sample program

The module begins with a sample Java program named **simple1** . The user is asked to enter some text and to terminate with the # character.

(This program contains a lot of code that you are not yet prepared to understand. For the time being, just concentrate on the use of variables in the program. You will learn about the other aspects of the program in future modules.)

The program loops, saving individual characters until encountering the # character. When it encounters the # character, it terminates and displays the character entered immediately prior to the # character.

2.22.4 Sample program named simple1

A complete listing of the program named **simple1** is provided in Listing 1 (p. 125) . Discussions of selected portions of the program are presented later in the module.

Listing 1 . Source code for the program named simple1.

```

This Java application reads bytes from the keyboard until
encountering the integer representation of '#'. At
the end of each iteration, it saves the byte received and
goes back to get the next byte.

When the '#' is entered, the program terminates input and
displays the character which was entered before the #.

2.22.4.1 Discussion of the simple1 program

Purpose

I will use the program shown in Listing 1 (p. 125) to discuss several important aspects of the structure of a Java program. I will also provide two additional sample programs that illustrate specific points not illustrated in the above program later in this module.

2.22.5 Variables

What is a variable? Variables are used in a Java program to contain data that changes during the execution of the program.

Declaring a variable

To use a variable, you must first notify the compiler of the *name* and the *type* of the variable. This is known as *declaring a variable* .

The syntax for declaring a variable is to precede the *name* of the variable with the *name of the type* of the variable as shown in Listing 2 (p. 126) . It is also possible (*but not always required*) to initialize a variable in Java when it is declared as shown in Listing 2 (p. 126) .

Listing 2 . Declaring and initializing two variables named ch1 and ch2.

```
int ch1, ch2 = '0';
```

Table 2.44

The statement in Listing 2 (p. 126) declares two variables of type **int** , initializing the second variable (*ch2*) to the value of the zero character (0). (*Note that I didn't say initialized to the value zero.*)

Difference between zero and '0' - Unicode characters The value of the zero character is not the same as the numeric value of zero, but hopefully you already knew that.

As an aside, characters in Java are 16-bit entities called Unicode characters instead of 8-bit entities as is the case with many programming languages. The purpose is to provide many more possible characters including characters used in alphabets other than the one used in the United States.

Initialization of the variable

Initialization of the variable named **ch2** in this case was necessary to prevent a compiler error. Without initialization of this variable, the compiler would recognize and balk at the possibility that an attempt might be made to execute the statement shown in Listing 3 (p. 127) with a variable named **ch2** that had not been initialized

Listing 3 . Display the character.

```
System.out.println("The char before the # was "
                  + (char)ch2);
```

Table 2.45**Error checking by the compiler**

The strong error-checking capability of the Java compiler would refuse to compile this program until that possibility was eliminated by initializing the variable.

Using the cast operator

You should also note that the contents of the variable `ch2` is being *cast* as type `char` in Listing 3 (p. 127) .

(A cast is used to change the type of something to a different type.)

Recall that `ch2` is a variable of type `int` , containing the numeric value that represents a character.

We want to display the character that the numeric value represents and not the numeric value itself. Therefore, we must cast it *(purposely change its type for the evaluation of the expression)* . Otherwise, we would not see the character on the screen. Rather, we would see the numeric value that represents that character.

Initialization of instance variables and local variables: As another aside, *member variables* in Java are automatically initialized to zero or the equivalent of zero. However, *local variables* , of which `ch2` is an example, are not automatically initialized.

Why declare the variables as type int?

It was necessary to declare these variables as type `int` because the statement in Listing 4 (p. 127) *(more specifically, the call to the `System.in.read` method)* returns a value of type `int` .

Listing 4 . Beginning of a while loop.

```
while( (ch1 = System.in.read() ) != '#') ch2 = ch1;
```

Table 2.46

Java provides very strict type checking and generally refuses to compile statements with type mismatches. *(There is a lot of complicated code in Listing 4 (p. 127) (p. 127) that I haven't previously explained. I will explain that code later in this and future modules.)*

Another variable declaration

The program in Listing 1 (p. 125) also makes another variable declaration shown by the statement in Listing 5 (p. 128) .

Listing 5 . Beginning of the main method.

```
public static void main(String[] args) //define main method
```

Table 2.47**An array of String references**

In Listing 5 (p. 128) , the formal argument list of the **main** method declares an argument named **args** (*first cousin to a variable*) as a reference to an array object of type **String** .

Capturing command-line arguments in Java

As you learned in an earlier module, this is the feature of Java that is used to capture arguments entered on the command line, and is required whether arguments are entered or not. In this case, no command-line arguments were entered, and the variable named **args** is simply ignored by the remainder of the program.

The purpose of the type of a variable

All variables must have a declared type The type determines the set of values that can be stored in the variable and the operations that can be performed on the variable.

For example, the **int** type can only contain whole numbers (*integers*) . A whole host of operations are possible with an **int** variable including add, subtract, divide, etc.

Signed vs. unsigned variables

Unlike C++, all variables of type **int** in Java contain signed values. In fact, with the exception of type **char** , all primitive numeric types in Java contain signed values.

Platform independence

At this point in the history of Java, a variable of a specified type is represented exactly the same way regardless of the platform on which the application or applet is being executed.

This is one of the features that causes compiled Java programs to be platform-independent.

2.22.5.1 Primitive types

In Java, there are two major categories of data types:

- primitive types
- reference (*or object*) types.

Primitive variables contain a single value of one of the eight primitive types shown in Listing 2 (p. 126) .

Reference variables contain references to objects (*or null, meaning that they don't refer to anything*) .

The eight primitive types in Java?

The table in Figure 2 (p. 128) lists all of the primitive types in Java along with their size and format, and a brief description of each.

Figure 2 . Information about the primitive types in Java.

continued on next page

Type	Size/Format	Description
byte	8-bit two's complement	Byte-length integer
short	16-bit two's complement	Short integer
int	32-bit two's complement	Integer
long	64-bit two's complement	Long Integer
float	32-bit IEEE 754 format	Single-precision floating point
double	64-bit IEEE 754 format	Double-precision floating point
char	16-bit Unicode character	Single character
boolean	true or false	True or False

Table 2.48

The char type

The **char** type is a 16-bit Unicode character value that has the possibility of representing more than 65,000 different characters.

Evaluating a primitive variable

A reference to the name of a primitive variable in program code evaluates to the value stored in the variable. In other words, when you call out the name of a primitive variable in your code, what you get back is the value stored in the variable.

2.22.5.1.1 Object-oriented wrappers for primitive types

Primitive types are not objects

Primitive data types in Java (*int*, *double*, etc.) are not objects. This has some ramifications as to how they can be used (*passing to methods*, *returning from methods*, etc.) .

The generic Object type

Later on in this course of study, you will learn that much of the power of Java derives from the ability to deal with objects of any type as the generic type **Object** . For example, several of the standard classes in the API (*such as the powerful Vector class*) are designed to work only with objects of type **Object** .

(Note that this document was originally published prior to the introduction of generics in Java. The introduction of generics makes it possible to cause the Vector class to deal with objects of types other than Object . However, that doesn't eliminate the need for wrapper classes.)

Converting primitives to objects

Because it is sometimes necessary to deal with a primitive value as though it were an object, Java provides *wrapper* classes that support object-oriented functionality for Java's primitive data types.

The Double wrapper class

This is illustrated in the program shown in Listing 6 (p. 129) that deals with a **double** type as an object of the class **Double** .

(Remember, Java is a case-sensitive language. Note the difference between the primitive double type and the class named Double .)

Listing 6 . The program named wrapper1.

continued on next page

```

This Java application illustrates the use of wrappers
for the primitive types.

This program produces the following output:

My wrapped double is 5.5
My primitive double is 10.5

*****/
class wrapper1 { //define the controlling class
    public static void main(String[] args){//define main

        //The following is the declaration and instantiation of
        // a Double object, or a double value wrapped in an
        // object. Note the use of the upper-case D.
        Double myWrappedData = new Double(5.5);

        //The following is the declaration and initialization
        // of a primitive double variable. Note the use of the
        // lower-case d.
        double myPrimitiveData = 10.5;

        //Note the call to the doubleValue() method to obtain
        // the value of the double wrapped in the Double
        // object.
        System.out.println(
            "My wrapped double is " + myWrappedData.doubleValue());
        System.out.println(
            "My primitive double is " + myPrimitiveData );
    }//end main
} //End wrapper1 class.

```

Table 2.49

The operation of this program is explained in the comments, and the output from the program is shown in the comments at the beginning.

2.22.5.2 Reference types

Once again, what is a primitive type?

Primitive types are types where the name of the variable evaluates to the value stored in the variable.

What is a reference type?

Reference types in Java are types where the name of the variable evaluates to the address of the location in memory where the object referenced by the variable is stored.

The above statement may not really be true? However, we can think of it that way. Depending on the particular JVM in use, the reference variable may refer to a table in memory where the address of the object is stored. In that case the second level of indirection is handled behind the scenes and we don't have to worry about it.

Why would a JVM elect to implement another level of indirection? Wouldn't that make programs run more slowly?

One reason has to do with the need to compact memory when it becomes highly fragmented. If the reference variables all refer directly to memory locations containing the objects, there may be many reference variables that refer to the same object. If that object is moved for compaction purposes, then the values stored in every one of those reference variables would have to be modified.

However, if those reference variables all refer to a table that has one entry that specifies where the object is stored, then when the object is moved, only the value of that one entry in the table must be modified.

Fortunately, that all takes place behind the scenes and we as programmers don't need to worry about it.

Primitive vs. reference variables

We will discuss this in more detail in a future module. For now, suffice it to say that in Java, a variable is either a primitive type or a reference type, and cannot be both.

Declaring, instantiating, initializing, and manipulating a reference variable

The fragment of code shown in Listing 7 (p. 131) , (which was taken from the program shown in Listing 6 (p. 129) (p. 129) that deals with wrappers) does the following. It

- declares,
- instantiates,
- initializes, and
- manipulates a variable of a reference type named `myWrappedData` .

In Listing 7 (p. 131) , the variable named `myWrappedData` contains a reference to an object of type `Double` .

Listing 7 . Aspects of using a wrapper class.

```
Double myWrappedData = new Double(5.5);

//Code deleted for brevity

//Note the use of the doubleValue() method to obtain the
// value of the double wrapped in the Double object.
System.out.println
    ("My wrapped double is " + myWrappedData.doubleValue() );
```

Table 2.50

2.22.5.3 Variable names

The rules for naming variables are shown in Figure 3 (p. 132) .

Figure 3 . Rules for naming variables.

- Must be a legal Java identifier (*see below*) consisting of a series of Unicode characters. Unicode characters are stored in sixteen bits, allowing for a very large number of different characters. A subset of the possible character values matches the 127 possible characters in the ASCII character set, and the extended 8-bit character set, ISO-Latin-1 (*The Java Handbook, page 60, by Patrick Naughton*).
- Must not be the same as a Java keyword and must not be true or false.
- Must not be the same as another variable whose declaration appears in the same scope.

Table 2.51

The rules for legal identifiers are shown in Figure 4 (p. 132) .

Figure 4 . Rules for legal identifiers.

- In Java, a legal identifier is a sequence of Unicode letters and digits of unlimited length.
- The first character must be a letter.
- All subsequent characters must be letters or numerals from any alphabet that Unicode supports.
- In addition, the underscore character (`_`) and the dollar sign (`$`) are considered letters and may be used as any character including the first one.

Table 2.52

2.22.6 Scope

What is the scope of a Java variable?

The scope of a Java variable is defined by the *block of code* within which the variable is accessible. (*Briefly, a block of code consists of none, one, or more statements enclosed by a pair of matching curly brackets.*)

The scope also determines when the variable is created (*memory set aside to contain the data stored in the variable*) and when it possibly becomes a candidate for destruction (*memory returned to the operating system for recycling and re-use*) .

Scope categories

The scope of a variable places it in one of the four categories shown in Figure 5 (p. 132) .

Figure 5 . Scope categories.

continued on next page

- member variable
- local variable
- method parameter
- exception handler parameter

Table 2.53**Member variable**

A member variable is a member of a class (*class variable*) or a member of an object instantiated from that class (*instance variable*). It must be declared within a class, but not within the body of a method or constructor of the class.

Local variable

A local variable is a variable declared within the body of a method or constructor or within a block of code contained within the body of a method or constructor.

Method parameters

Method parameters are the formal arguments of a method. Method parameters are used to pass values into and out of methods. The scope of a method parameter is the entire method for which it is a parameter.

Exception handler parameters

Exception handler parameters are arguments to exception handlers. Exception handlers will be discussed in a future module.

Illustrating different types of variables in Java

The Java program shown in Listing 8 (p. 134) illustrates

- member variables (*class and instance*),
- local variables, and
- method parameters.

An illustration of exception handler parameters will be deferred until exception handlers are discussed in a future module.

Listing 8 . The program named member1.

```

/*File member1.java Copyright 1997, R.G.Baldwin

variables, local variables, and method parameters.

Output from this program is:

Class variable is 5
Instance variable is 6
Method parameter is 7
Local variable is 8

*****/
class member1 { //define the controlling class
  //declare and initialize class variable
  static int classVariable = 5;
  //declare and initialize instance variable
  int instanceVariable = 6;

  public static void main(String[] args){ //main method
    System.out.println("Class variable is "
                      + classVariable);

    //Instantiate an object of the class to allow for
    // access to instance variable and method.
    member1 obj = new member1();
    System.out.println("Instance variable is "
                      + obj.instanceVariable);
    obj.myMethod(7); //call the method

    //declare and initialize a local variable
    int localVariable = 8;
    System.out.println("Local variable is "
                      + localVariable);

  } //end main

  void myMethod(int methodParameter){
    System.out.println("Method parameter is "
                      + methodParameter);
  } //end myMethod
} //End member1 class.

```

Table 2.54**Declaration of local variables**

In Java, local variables are declared within the body of a method or within a block of code contained within the body of a method.

Scope of local variables

The scope of a local variable extends from the point at which it is declared to the end of the block of code in which it is declared.

What is a "block" of code?

A block of code is defined by enclosing it within curly brackets as in { ... }.

Therefore, the scope of a local variable can be the entire method, or can be reduced by declaring it within a block of code within the method.

Special case, scope within a for loop Java treats the scope of a variable declared within the initialization clause of a **for** statement to be limited to the total extent of the **for** statement.

A future module will explain what is meant by a **for** statement or a **for** loop.

2.22.7 Initialization of variables

Initializing primitive local variables

Local variables of primitive types can be initialized when they are declared using statements such as the one shown in Listing 9 (p. 135) .

Listing 9 . Initialization of variables.
<pre>int MyVar, UrVar = 6, HisVar;</pre>

Table 2.55

Initializing member variables

Member variables can also be initialized when they are declared.

In both cases, the type of the value used to initialize the variable must match the type of the variable.

Initializing method parameters and exception handler parameters

Method parameters and exception handler parameters are initialized by the values passed to the method or exception handler by the calling program.

2.22.8 Run the programs

I encourage you to copy the code from Listing 1 (p. 125) , Listing 6 (p. 129) , and Listing 8 (p. 134) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

2.22.9 Miscellaneous

This section contains a variety of miscellaneous information.

Method parameters are the formal arguments of a method. Method parameters are used to pass values into and out of methods.

Back to Question 34 (p. 141)

2.23.5.7 Answer 33

Java treats the scope of a variable declared within the initialization clause of a *for* statement to be limited to the total extent of the *for* statement. A sample code fragment follows where **cnt** is the variable being discussed:

```
for(int cnt = 0; cnt < max; cnt++){
    //do something
} //end of
```

Back to Question 33 (p. 140)

2.23.5.8 Answer 32

In Java, the scope can be reduced by placing it within a block of code within the method. The *scope* extends from the point at which it is declared to the end of the block of code in which it is declared.

2.23.5.10 Answer 30

The *scope* of a local variable extends from the point at which it is declared to the end of the block of code in which it is declared.

2.23.5.11 Answer 29

In Java, *local variables* are declared within the body of a method or constructor, or within a block of code contained within the body of a method or constructor.

Back to Question 29 (p. 140)

2.23.5.12 Answer 28

A *member variable* is a member of a class (*class* variable) or a member of an object instantiated from that class (*instance* variable). It must be declared within a class, but not within the body of a method or constructor of the class.

Back to Question 28 (p. 140)

2.23.5.13 Answer 27

The *scope* of a variable places it in one of the following four categories:

- member variable
- local variable
- method parameter
- exception handler parameter

Back to Question 27 (p. 140)

2.23.5.14 Answer 26

The *scope* of a Java variable is the block of code within which the variable is accessible.

Back to Question 26 (p. 140)

2.23.5.15 Answer 25

The rules for Java variable names are as follows:

- Must be a legal Java identifier consisting of a series of *Unicode* characters.
- Must not be the same as a Java *keyword* and must not be *true* or *false*.
- Must not be the same as another variable whose declaration appears in the same scope.

Back to Question 25 (p. 140)

2.23.5.16 Answer 24

In Java, a legal identifier is a sequence of Unicode letters and digits of unlimited length. The first character must be a letter. All subsequent characters must be letters or numerals from any alphabet that Unicode supports. In addition, the underscore character (`_`) and the dollar sign (`$`) are considered letters and may be used as any character including the first one.

Back to Question 24 (p. 140)

2.23.5.17 Answer 23

False. The name of a reference variable evaluates to either null, or to information that can be used to access an object whose reference has been stored in the variable.

2.23.5.18 Answer 22

Later versions of Java support either syntax shown in Listing 1 (p. 145) .

2.23.5.19 Answer 21

The proper syntax for early versions of Java is shown below. Note the upper-case **D** . Also note the instantiation of a new object of type **Double** .

```
Double myWrappedData = new Double(5.5);
```

Later versions of Java support the following syntax with the new object of type **Double** being instantiated automatically:

```
Double myWrappedData = 5.5;
```

Back to Question 21 (p. 139)

2.23.5.20 Answer 20

The proper syntax is shown below. Note the lower-case `d` .

```
double myPrimitiveData = 5.5;
```

Back to Question 20 (p. 139)

2.23.5.21 Answer 19

The name of the *primitive* type begins with a lower-case letter and the name of the *wrapper* type begins with an upper-case letter such as `double` and `Double` . Note that in some cases, however, that they are not spelled the same. For example, the `Integer` class is the wrapper for type `int` .

2.23.5.22 Answer 18

Back to Question 18 (p. 139)

2.23.5.23 Answer 17

This has some ramifications as to how variables can be used (*passing to methods, returning from methods, etc.*) . For example, all variables of *primitive* types are passed by value to methods meaning that the code in the method only has access to a copy of the variable and does not have the ability to modify the variable.

False. In Java, all variables of type **int** contain signed values.

Back to Question 9 (p. 138)

2.23.5.32 Answer 8

Back to Question 8 (p. 138)

2.23.5.33 Answer 7

The syntax is shown in boldface below:

```
public static void main( String[] args )
```

In this case, the type of variable declared is an array of type **String** named **args** (*type String[]*) . The purpose of the **String** array variable in the argument list is to make it possible to capture arguments entered on the command line.

2.24.3 Introduction

The first step in learning to use a new programming language is usually to learn the foundation concepts such as

- variables,
- operators,
- types,
- expressions,
- flow-of-control, etc.

This module concentrates on the **operators** used in Java.

2.24.4 Operators

Unary and binary operators

Java provides a set of operators that can be used to perform an action on one, two, or three (p. 150) operands. An operator that operates on one operand is called a *unary* operator. An operator that operates on two operands is called a *binary* operator. An operator that operates on three operands is called a *ternary* operator.

Some operators can behave either as a unary or as a binary operator. The best known such operator is probably the minus sign (-) . As a binary operator, the minus sign causes its right operand to be subtracted from its left operand. As a unary operator, the minus sign causes the algebraic sign of the right operand to be changed.

A ternary operator

Java has only one operator that takes three operands. It is a conditional operator, which I sometimes refer to as a cheap **if** statement.

The first operand is a **boolean** expression, which is followed by a question mark character (?) . The question mark is followed by a second operand, which is followed by a colon character (:) . The colon character is followed by the third operand.

If the **boolean** expression evaluates to true, the value of the operand following the ? is returned. Otherwise, the value of the operand following the : is returned.

An example of the syntax follows:

Ternary operator syntax boolean expression ? value1 : value2

Overloaded operators

Unlike C++, Java does not support the creation of overloaded operators in program code. (*If you don't know what this means, don't worry about it.*)

Operators from previous programs

The statements in the following note box illustrate the use of the following operators from Java **programs in earlier modules** :

- =
- !=
- +
- (char)

Operators from previous programs

```
int ch1, ch2 = '0';
while( (ch1 = System.in.read() ) != '#') ch2 = ch1;
System.out.println("The char before the # was "
                   + (char)ch2);
```

The plus and cast operators

Of particular interest in this list (p. 151) is the plus sign (+) and the cast operator (char) .

In Java, the plus sign can be used to perform arithmetic addition. It can also be used to concatenate strings. When the plus sign is used in the manner shown above (p. 151) , the operand on the right is automatically converted to a character string before being concatenated with the operand on the left.

The cast operator is used in this case (p. 151) to purposely convert the integer value contained in the **int** variable **ch2** to a character type suitable for concatenating with the string on the left of the plus sign. Otherwise, Java would attempt to convert and display the value of the **int** variable as a series of digits representing the *numeric value* of the character because the character is stored in a variable of type **int** .

The increment operator

An extremely important *unary* operator is the increment operator identified by two plus characters with no space between them (++) .

The increment operator causes the value of its operand to be increased by one.

The decrement operator There is also a decrement operator (-) that causes the value of its operand to be decreased by one.

The increment and decrement operators are used in both *prefix* and *postfix* notation.

Prefix and postfix increment and decrement operators

With the *prefix* version, the operand appears to the right of the operator (++X) , while with the *postfix* version, the operand appears to the left of the operator (X++) .

What's the difference in prefix and postfix?

The difference in prefix and postfix has to do with the point in the sequence of operations that the increment (or decrement) actually occurs if the operator and its operand appear as part of a larger overall expression.

(There is effectively no difference if the operator and its operand do not appear as part of a larger overall expression.)

Prefix behavior

With the *prefix* version, the variable is incremented (or decremented) before it is used to evaluate the larger overall expression.

Postfix behavior

With the *postfix* version, the variable is used to evaluate the larger overall expression before it is incremented (or decremented) .

Illustration of prefix and postfix behavior

The use of both the *prefix* and *postfix* versions of the increment operator is illustrated in the Java program shown in Listing 1 (p. 153) . The output produced by the program is show in the comments at the beginning of the program.

Listing 1 . Illustration of prefix and postfix notation.

```

The output from the program follows:

c + ++d = 11
d = 6

class incr01 { //define the controlling class

    System.out.println("a = " + a );
    System.out.println("b = " + b );
    System.out.println("a + b++ = " + (a + b++) );
    System.out.println("b = " + b );
    System.out.println();

    System.out.println("c = " + c );
    System.out.println("d = " + d );
    System.out.println("c + ++d = " + (c + ++d) );
    System.out.println("d = " + d );
  } //end main
} //End incr01 class.

```

Table 2.58**Binary operators and infix notation**

Binary operators use *infix* notation, which means that the operator appears between its operands.

General behavior of an operator

As a result of performing the specified action, an operator can be said to return a value (*or evaluate to a value*) of a given type. The type of value returned depends on the operator and the type of the operands.

Evaluating to a value To evaluate to a value means that after the action is performed, the operator and its operands are effectively replaced in the expression by the value that is returned.

Operator categories

I will divide Java's operators into the following categories for further discussion:

- arithmetic operators

- relational and conditional (*logical*) operators
- bitwise operators
- assignment operators

2.24.4.1 Arithmetic operators

Java supports various arithmetic operators on all floating point and integer numbers.

The binary arithmetic operators

The following table lists the *binary* arithmetic operators supported by Java.

The binary arithmetic operators

Operator	Description
+	Adds its operands
-	Subtracts the right operand from the left operand
*	Multiplies the operands
/	Divides the left operand by the right operand
%	Remainder of dividing the left operand by the right operand

String concatenation

As mentioned earlier, the plus operator (+) is also used to concatenate strings as in the following code fragment:

String concatenation

```
"MyVariable has a value of "
    + MyVariable + " in this program."
```

Coercion

Note that this operation (p. 154) also coerces the value of **MyVariable** to a string representation for use in the expression only. However, the value stored in the variable is not modified in any lasting way.

Unary arithmetic operators

Java supports the following *unary* arithmetic operators.

Unary arithmetic operators

Operator	Description
+	Indicates a positive value
-	Negates, or changes algebraic sign
++	Adds one to the operand, both prefix and postfix
--	Subtracts one from operand, both prefix and postfix

The result of the increment and decrement operators being either *prefix* or *postfix* was discussed earlier (p. 151) .

2.24.4.2 Relational and conditional (logical) operators

Binary Relational operators

Java supports the set of *binary* relational operators shown in the following table. Relational operators in Java return either *true* or *false* as a **boolean** type.

Binary Relational operators

Operator	Returns true if
>	Left operand is greater than right operand
>=	Left operand is greater than or equal to right operand
<	Left operand is less than right operand
<=	Left operand is less than or equal to right operand
==	Left operand is equal to right operand
!=	Left operand is not equal to right operand

Conditional expressions

Relational operators are frequently used in the conditional expressions of control statement such as the one in the code fragment shown below.

Conditional expressions

```
if(LeftVariable <= RightVariable). . .
```

Illustration of relational operators

The program shown in Listing 2 (p. 155) illustrates the result of applying relational operators in Java. The output is shown in the comments at the beginning of the program. Note that the program automatically displays **true** and **false** as a result of applying the relational operators.

Listing 2 . Illustration of relational operators.

```
/*File relat01.java Copyright 1997, R.G.Baldwin
Illustrates relational operators.

Output is

The relational 6<5 is false
The relational 6>5 is true

*****/
class relat01 { //define the controlling class
  public static void main(String[] args){ //main method
    System.out.println("The relational 6<5 is "
      +(6<5));
    System.out.println("The relational 6>5 is "
      +(6>5));
  } //end main
} //End relat01 class.
```

Table 2.59

Conditional operators

The relational operators are often combined with another set of operators (*referred to as conditional or logical operators*) to construct more complex expressions.

Java supports three such operators as shown in the following table.

Conditional or logical operators

Operator	Typical Use	Returns true if
<code>&&</code>	Left <code>&&</code> Right	Left and Right are both true
<code> </code>	Left <code> </code> Right	Either Left or Right is true
<code>!</code>	<code>! Right</code>	Right is false

The operands shown in the table (p. 156) must be **boolean** types, or must have been created by the evaluation of an expression that returns a **boolean** type.

Left to right evaluation

An important characteristic of the behavior of the logical **and** and the logical **or** operators is that the expressions are evaluated from left to right, and the evaluation of the expression is terminated as soon as the result of evaluating the expression can be determined.

For example, in the following expression, if the variable **a** is less than the variable **b**, there is no need to evaluate the right operand of the `||` to determine that the result of evaluating the entire expression would be **true**. Therefore, evaluation will terminate as soon as the answer can be determined.

Left to right evaluation

```
(a < b) || (c < d)
```

Don't confuse bitwise and with logical and

As discussed in the next section, the symbols shown below are the bitwise **and** and the bitwise **or**.

Bitwise and and bitwise or

```
& bitwise and
| bitwise or
```

One author states that in Java, the bitwise **and** operator can be used as a synonym for the logical **and** and the bitwise **or** can be used as a synonym for the logical **inclusive or** if both of the operands are **boolean**. (*I recommend that you don't do that because it could cause confusion for someone reading your code.*)

Note however that according to a different author, in this case, the evaluation of the expression is not terminated until all operands have been evaluated, thus eliminating the possible advantage of the left-to-right evaluation.

2.24.4.3 Bitwise operators

Java provides a set of operators that perform actions on their operands one bit at a time as shown in the following table.

Bitwise operators

Operator	Typical Use	Operation
<code>>></code>	<code>OpLeft >> Dist</code>	Shift bits of <code>OpLeft</code> right by <code>Dist</code> bits (signed)
<code><<</code>	<code>OpLeft << Dist</code>	Shift bits of <code>OpLeft</code> left by <code>Dist</code> bits
<code>>>></code>	<code>OpLeft >>> Dist</code>	Shift bits of <code>OpLeft</code> right by <code>Dist</code> bits (unsigned)
<code>&</code>	<code>OpLeft & OpRight</code>	Bitwise and of the two operands
<code> </code>	<code>OpLeft OpRight</code>	Bitwise

Populating vacated bits for shift operations

The *signed* right shift operation populates the vacated bits with the sign bit, while the left shift and the *unsigned* right shift populate the vacated bits with zeros.

In all cases, bits shifted off the end are lost.

The rule for bitwise **and**

The bitwise **and** operation operates according to the rule that the bitwise **and** of two 1 bits is a 1 bit. Any other combination results in a 0 bit.

Bitwise inclusive **or**

For the *inclusive or*, if either bit is a 1, the result is a 1.

Otherwise, the result is a 0.

Bitwise exclusive **or**

For the *exclusive or*, if either but not both bits is a 1, the result is a 1.

Otherwise, the result is a 0.

Another way to state this is if the bits are different, the result is a 1. If the two bits are the same, the result is a 0.

The complement operator

Finally, the complement operator changes each 1 to a 0 and changes each 0 to a 1.

2.24.4.4 Assignment operators

Simple assignment operator

The `(=)` is a value assigning *binary* operator in Java. The value stored in memory and represented by the right operand is copied into the memory represented by the left operand.

Using the assignment operator with reference variables

You need to be careful and think about what you are doing when you use the assignment operator with reference variables in Java. If you assign one reference variable to another, you simply end up with two reference variables that refer to the same object. You do not end up with two different objects.

*(If what you need is another copy of the object, you may be able to use the **clone** method to accomplish that.)*

Shortcut assignment operators

Java supports the following list of *shortcut* assignment operators. These operators allow you to perform an assignment and another operation with a single operator.

Shortcut assignment operators

```
+=
-=
* =
```

```

/=
%=
&=
|=
^=
<<=
>>=
>>>=

```

For example, the two statements that follow perform the same operation.

Illustration of shortcut assignment operation

```

x += y;
x = x + y;

```

Back to Question 36 (p. 164)

2.25.5.4 Answer 35

Java supports the following list of *shortcut* assignment operators. These operators allow you to perform an assignment and another operation with a single operator.

```

+=
-=
*=
/=
%=
&=
|=
^=
<<=
>>=
>>>=

```

For example, the two statements that follow perform the same operation.

- $x += y;$
- $x = x + y;$

The behavior of each of the *shortcut* assignment operators follows this same pattern.

Back to Question 35 (p. 164)

2.25.5.5 Answer 34

True.

Back to Question 34 (p. 164)

2.25.5.6 Answer 33

The assignment operator is a *binary* operator.

Back to Question 33 (p. 163)

2.25.5.7 Answer 32

True.

Back to Question 32 (p. 163)

2.25.5.8 Answer 31

The answer for the bitwise *exclusive or* is:

- 11 1 xor 1 produces 0
- 10 1 xor 0 produces 1
- 01 0 xor 1 produces 1
- 00 0 xor 0 produces 0

Back to Question 31 (p. 163)

2.25.5.9 Answer 30

The answer for the bitwise *inclusive or* is:

- 11 1 or 1 produces 1
- 10 1 or 0 produces 1
- 01 0 or 1 produces 1
- 00 0 or 0 produces 0

Back to Question 30 (p. 163)

2.25.5.10 Answer 29

The answer for the bitwise **and** is:

- 11 1 and 1 produces 1
- 10 1 and 0 produces 0
- 01 0 and 1 produces 0
- 00 0 and 0 produces 0

Back to Question 29 (p. 163)

2.25.5.11 Answer 28

True: Bits shifted off the right end are lost.

Back to Question 28 (p. 163)

2.25.5.12 Answer 27

False: In Java, the *signed* right shift operation populates the vacated bits with the sign bit, while the left shift and the *unsigned* right shift populate the vacated bits with zeros.

Back to Question 27 (p. 163)

2.25.5.13 Answer 26

The following table shows the seven bitwise operators supported by Java.

Bitwise operators

Operator	Typical Use	Operation
<code>>></code>	<code>OpLeft >> Dist</code>	Shift bits of <code>OpLeft</code> right by <code>Dist</code> bits (signed)
<code><<</code>	<code>OpLeft << Dist</code>	Shift bits of <code>OpLeft</code> left by <code>Dist</code> bits
<code>>>></code>	<code>OpLeft >>> Dist</code>	Shift bits of <code>OpLeft</code> right by <code>Dist</code> bits (unsigned)
<code>&</code>	<code>OpLeft & OpRight</code>	Bitwise and of the two operands
<code> </code>	<code>OpLeft OpRight</code>	Bitwise

Back to Question 26 (p. 163)

2.25.5.14 Answer 25

The bitwise ***and*** operator and the bitwise ***inclusive or*** operator are shown below.

Two bitwise operators

```
& bitwise and
| bitwise inclusive or
```

Back to Question 25 (p. 163)

2.25.5.15 Answer 24

An important characteristic of the behavior of the ***logical and*** operator and the ***logical or*** operator in Java is that the expressions containing them are evaluated from *left to right*. The evaluation of the expression is terminated as soon as the result of evaluating the expression can be determined. For example, in the expression given in Question 24 (p. 162), if the variable ***a*** is less than the variable ***b***, there is no need to evaluate the right operand of the `||` operator to determine the value of the entire expression. Therefore, evaluation will terminate as soon as it is determined that ***a*** is less than ***b***.

Back to Question 24 (p. 162)

2.25.5.16 Answer 23

The following three *logical* or *conditional* operators are supported by Java.

The logical or conditional operators

Operator	Typical Use	Returns true if
&&	Left && Right	Left and Right are both true
	Left Right	Either Left or Right is true
!	! Right	Right is false

Back to Question 23 (p. 162)

2.25.5.17 Answer 22

This program produces the following output:

```
The relational 6<5 is false
The relational 6>5 is true
```

Back to Question 22 (p. 162)

2.25.5.18 Answer 21

Java supports the following set of *relational* operators:

Relational operators

Operator	Returns true if
>	Left operand is greater than right operand
>=	Left operand is greater than or equal to right operand
<	Left operand is less than right operand
<=	Left operand is less than or equal to right operand
==	Left operand is equal to right operand
!=	Left operand is not equal to right operand

Back to Question 21 (p. 162)

2.25.5.19 Answer 20

Relational operators return the **boolean** type in Java.

Back to Question 20 (p. 162)

2.25.5.20 Answer 19

Java supports the following four *unary* arithmetic operators.

Unary arithmetic operators

Operator	Description
+	Indicates a positive value
-	Negates, or changes algebraic sign
++	Adds one to the operand, both prefix and postfix
--	Subtracts one from operand, both prefix and postfix

Back to Question 19 (p. 162)

2.25.5.21 Answer 18

The operator coerces the value of the right operand to a string representation for use in the expression only. If the right operand is a variable, the value stored in the variable is not modified in any way.

Back to Question 18 (p. 161)

2.25.5.22 Answer 17

The plus operator (+) is also used to concatenate strings as in the following code fragment:

String concatenation

```
"MyVariable has a value of "
  + MyVariable + " in this program."
```

Back to Question 17 (p. 161)

2.25.5.23 Answer 16

Java support various arithmetic operators on floating point and integer numbers. The following table lists five of the *binary* arithmetic operators supported by Java.

Binary arithmetic operators

Operator	Description
+	Adds its operands
-	Subtracts the right operand from the left operand
*	Multiplies the operands
/	Divides the left operand by the right operand
%	Remainder of dividing the left operand by the right operand

Back to Question 16 (p. 161)

2.25.5.24 Answer 15

As a result of performing the specified action, an operator can be said to return a value (*or evaluate to a value*) of a given type. The type depends on the operator and the type of the operands. To *evaluate to a value* means that after the action is performed, the operator and its operands are effectively replaced in the expression by the value that is returned.

Back to Question 15 (p. 161)

2.25.5.25 Answer 14

False: *Binary* operators use *infix* notation, which means that the operator appears between its operands.

Back to Question 14 (p. 161)

2.25.5.26 Answer 13

The output from this Java application follows:

- x = 5
- X = 5
- x + X++ = 10
- X = 6
- y = 5
- Y = 5
- y + ++Y = 11
- Y = 6

Back to Question 13 (p. 160)

2.25.5.27 Answer 12

The increment operator may be used with both *prefix* and *postfix* notation. Basically, the increment operator causes the value of the variable to which it is applied to be increased by one.

With *prefix* notation, the operand appears to the right of the operator ($++X$), while with *postfix* notation, the operand appears to the left of the operator ($X++$).

The difference in behavior has to do with the point in the sequence of operations that the increment actually occurs.

With the *prefix* version, the variable is incremented before it is used to evaluate the larger overall expression in which it appears. With the *postfix* version, the variable is used to evaluate the larger overall expression and then the variable is incremented.

Back to Question 12 (p. 160)

2.25.5.28 Answer 11

The symbol for the increment operator is two plus signs with no space between them ($++$).

Back to Question 11 (p. 160)

2.25.5.29 Answer 10

False: The increment operator is a *unary* operator.

Back to Question 10 (p. 160)

2.25.5.30 Answer 9

The cast operator is used to purposely convert from one type to another.

Back to Question 9 (p. 160)

2.25.5.31 Answer 8

The plus sign (+) is automatically overloaded in Java. The plus sign can be used to perform arithmetic addition. It can also be used to concatenate strings. However, the plus sign does more than concatenate strings. It also performs a conversion to **String** type. When the plus sign is used to concatenate strings and one operand is a string, the other operand is automatically converted to a character string before being concatenated with the existing string.

Back to Question 8 (p. 160)

2.25.5.32 Answer 7

The operators listed in order are:

- =
- !=
- +
- (char)

where the cast operator is being used to cast to the type **char** .

Back to Question 7 (p. 160)

2.25.5.33 Answer 6

Java does not support operator overloading by programmers.

Back to Question 6 (p. 160)

2.25.5.34 Answer 5

For those languages that support it (*such as C++*) operator overloading means that the programmer can redefine the behavior of an operator with respect to objects of a new type defined by that program.

Back to Question 5 (p. 160)

2.25.5.35 Answer 4

Both. As a *binary* operator, the minus sign causes its right operand to be subtracted from its left operand. As a *unary* operator, the minus sign causes the algebraic sign of the right operand to be changed.

Back to Question 4 (p. 160)

2.26.3 Introduction

The first step

The first step in learning to use a new programming language is usually to learn the foundation concepts such as variables, types, expressions, flow-of-control, etc. This module concentrates on expressions and statements.

2.26.4 Expressions

The hierarchy

Java programs are composed of statements, and statements are constructed from expressions.

An expression is a specific combination of operators and operands, that evaluates to a single value. The operands can be variables, constants, or method calls.

A method call evaluates to the value returned by the method.

Named constants

Java supports named constants that are implemented through the use of the **final** keyword.

The syntax for creating a named constant in Java is as follows:

Named constants

```
final float PI = 3.14159;
```

While this is not a constant type, it does produce a value that can be referenced in the program and which cannot be modified.

The **final** keyword prevents the value of **PI** from being modified in this case (p. 177) . You will learn later that there are some other uses for the **final** keyword in Java as well.

Operator precedence

The order in which the operations are performed determines the result. You can control the order of evaluation by the use of matching parentheses.

If you don't provide such parentheses, the order will be determined by the precedence of the operators (*you should find and review a table of Java operator precedence*) with the operations having higher precedence being evaluated first.

2.26.5 Statements

According to The Java Tutorials ¹³⁰ , *"A statement forms a complete unit of execution."*

A statement is constructed by combining one or more expressions into a compound expression and terminating that expression with a semicolon.

2.27.4 Answers

2.27.4.1 Answer 9

If you don't provide matching parentheses to control the order of evaluation, the order will be determined by the precedence of the operators with the operations having higher precedence being evaluated first. For example, multiply and divide have higher precedence than add and subtract.

2.28.3 Introduction

The first step

The first step in learning to use a new programming language is usually to learn the foundation concepts such as variables, types, expressions, flow-of-control, etc. This module concentrates on *flow-of-control* .

2.28.4 Flow of control

What is flow of control?

Java supports several different kinds of statements designed to alter or control the logical flow of the program.

The ability to alter the logical flow of the program is often referred to as *Flow of Control* .

Statements that support flow of control

Figure 1 (p. 185) lists the statements supported by Java for controlling the logical flow of the program.

Figure 1 . Statements that support flow of control.	
Statement	Type
if-else	selection
switch-case	selection
for	loop
for-each	loop
while	loop
do-while	loop
try-catch-finally	exception handling
throw	exception handling
break	miscellaneous
continue	miscellaneous
label:	miscellaneous
return	miscellaneous
goto	reserved by Java but not supported

Table 2.65

2.28.4.1 The while statement

We've seen the **while** statement in earlier modules. Several of the programs in earlier modules contained a **while** statement designed to control the logical flow of the program.

Syntax of a while statement

The general syntax of a **while** statement is shown in Figure 2 (p. 186) .

Figure 2 . Syntax of a while statement.

```
while (conditional expression)
    statement or compound statement;
```

Table 2.66**Behavior of a while statement**

The **three pillars** of procedural programming are

- sequence
- selection
- loop

The **while** statement is commonly used to create a loop structure, often referred to as a *while loop* .

Once the **while** statement is encountered in the sequence of code, the program will continue to execute the statement or compound statement shown in Figure 2 (p. 186) for as long as the conditional expression evaluates to true. (*Note that a compound statement is created by enclosing two or more statements inside a pair of matching curly brackets, thus creating a block of code as the body of the **while** statement or loop.*)

Sample Java while statement

The **while** statement shown in Listing 1 (p. 186) was extracted from a Java program in an earlier module.

Listing 1 . Sample Java while statement.

```
while( (ch1 = System.in.read() ) != '#')
    ch2 = ch1;
```

Table 2.67**The in variable of the System class**

The **System** class defines a *class* variable named **in** . Because it is a *class* variable, it can be accessed using the name of the **System** class without the requirement to instantiate an object of the **System** class.

What the in variable contains

The **in** variable refers to an instance of a class that provides a **read** method that returns a character from the standard input device (*typically the keyboard*) .

Therefore, the expression **System.in.read()** in Listing 1 (p. 186) constitutes a call to the **read** method of the object referred to by the **in** variable of the **System** class.

A while loop is an entry condition loop

The **while** statement is used to form an *entry condition* loop. The significance of an entry condition loop is that the conditional expression is tested before the statements in the loop are executed. If it tests false initially, the statements in the loop are never executed.

The **while** loop shown in Listing 1 (p. 186) will continue reading characters from the keyboard for as long as the character entered is not the # character. (*Recall the not equal (!=) operator from an earlier module.*)

2.28.4.2 The if-else statement

The general syntax of an **if-else** statement is shown in Figure 3 (p. 187) .

Figure 3 . Syntax of an if-else statement.

```
if(conditional expression)
    statement or compound statement;
else //optional
    statement or compound statement; //optional
```

Table 2.68

The **if-else** statement is the most basic of the statements used to control the logical flow of a Java program. It is used to satisfy the *selection* pillar mentioned earlier (p. 186) .

This statement will execute a specified block of code if some particular condition is true, and optionally, will execute a different block of code if the condition is not true.

The **else** clause shown in Figure 3 (p. 187) is optional. If it is not provided and the condition is not true, control simply passes to the next statement following the **if** statement with none of the code in the body of the **if** statement being executed. If the condition is true, the code in the body of the **if** statement is executed.

If the **else** clause is provided and the condition is true, the code in the body of the **if** clause is executed and the code in the body of the **else** clause is ignored.

If the **else** clause is provided and the condition is false, the code in the body of the **if** clause is ignored and the code in the body of the **else** clause is executed.

In all cases, control passes to the next statement following the **if-else** statement when the code in the **if-else** statement has finished executing. In other words, this is not a loop structure.

2.28.4.3 The switch-case statement

The **switch-case** statement is another implementation of the *selection* pillar mentioned earlier (p. 186) . The general syntax of a **switch-case** statement is shown in Figure 4 (p. 188) .

Figure 4 . Syntax of a switch-case statement.

```

switch(expression){
  case constant:
    //sequence of optional statements
    break; //optional
  case constant:
    //sequence of optional statements
    break; //optional
  .
  .
  .
  default //optional
    //sequence of optional statements
}

```

Table 2.69**The type of the *expression***

According to the book, *Java Language Reference* , by Mark Grand, the expression shown in the first line in Figure 4 (p. 188) must be of type **byte** , **char** , **short** , or **int** .

The behavior of the switch-case statement

The expression is tested against a series of *case* constants of the same type as the expression. If a match is found, the sequence of optional statements associated with that *case* is executed.

Execution of statements continues until the optional **break** is encountered. When **break** is encountered, execution of the switch statement is terminated and control passes to the next statement following the switch statement.

If there is no **break** statement, all of the statements following the matching case will be executed including those in cases further down the page.

The optional default keyword

If no match is found and the optional default keyword along with a sequence of optional statements has been provided, those statements will be executed.

Labeled break

Java also supports labeled break statements. This capability can be used to cause Java to exhibit different behavior when switch statements are nested. This will be explained more fully in a later section on labeled break statements.

2.28.4.4 The for loop

The **for** statement is another implementation of the *loop* pillar mentioned earlier (p. 186) .

Actions of a *for loop*

The operation of a loop normally involves three actions in addition to executing the code in the body of the loop:

- Initialize a control variable.
- Test the control variable in a conditional expression.
- Update the control variable.

Grouping the actions

Java provides the **for** loop construct that groups these three actions in one place.

The syntax of a for loop

A **for** loop consists of three clauses separated by semicolons as shown in Figure 5 (p. 189) .

Figure 5 . Syntax of a for loop.

```
for (first clause; second clause; third clause)
    single or compound statement
```

Table 2.70

Contents of the clauses

The first and third clauses can contain one or more expressions, separated by the *comma operator* .

The comma operator

The comma operator guarantees that its left operand will be executed before its right operand.

(While the comma operator has other uses in C++, this is the only use of the comma operator in Java.)

Behavior and purpose of the first clause

The expressions in the first clause are executed only once, at the beginning of the loop. Any legal expression(s) may be contained in the first clause, but typically the first clause is used for initialization.

Declaring and initializing variables in the first clause

Variables can be declared and initialized in the first clause, and this has an interesting ramification regarding scope that will be discussed later.

Behavior of the second clause

The second clause consists of a single expression that must evaluate to a **boolean** type with a value of true or false. The expression in the second clause must eventually evaluate to false to cause the loop to terminate.

Typically relational expressions or relational and conditional expressions are used in the second clause.

When the test is performed

The value of the second clause is tested when the statement first begins execution, and at the beginning of each iteration thereafter. Therefore, just like the **while** loop, the **for** loop is an *entry condition loop* .

When the third clause is executed

Although the third clause appears physically at the top of the loop, it isn't executed until the statements in the body of the loop have completed execution.

This is an important point since this clause is typically used to update the control variable, and perhaps other variables as well.

What the third clause can contain

Multiple expressions can appear in the third clause, separated by the comma operator. Again, those expressions will be executed from left to right. If variables are updated in the third clause and used in the body of the loop, it is important to understand that they do not get updated until the execution of the body is completed.

Declaring a variable in a for loop

As mentioned earlier, it is allowable to declare variables in the first clause of a **for** loop.

You can declare a variable with a given name outside (*prior to*) the **for** loop, or you can declare it inside the **for** loop, but not both.

If you declare it outside the **for** loop, you can access it either outside or inside the loop.

If you declare it inside the loop, you can access it only inside the loop. In other words, the scope of variables declared inside a **for** loop is limited to the loop.

This is illustrated in following sequence of four simple programs.

This program won't compile

The Java program shown in Listing 2 (p. 190) refuses to compile with a complaint that a variable named **cnt** has already been declared in the method when the attempt is made to declare it in the **for** loop.

Listing 2 . A program that won't compile.

```

/*File for1.java Copyright 1997, R.G.Baldwin
This program will not compile because the variable
named cnt is declared twice.
*****/
class for1 { //define the controlling class
  public static void main(String[] args){ //main method
    int cnt = 5; //declare local method variable
    System.out.println(
      "Value of method var named cnt is " + cnt);

    for(int cnt = 0; cnt < 2; cnt++)
      System.out.println(
        "Value of loop var named cnt is " + cnt);

    System.out.println(
      "Value of method var named cnt is " + cnt);
  } //end main
} //End controlling class. Note no semicolon required

```

Table 2.71

The program shown in Listing 3 (p. 191) also won't compile, but for a different reason.

Listing 3 . Another program that won't compile.

```

/*File for2.java Copyright 1997, R.G.Baldwin
This program will not compile because the variable
declared inside the for loop is not accessible
outside the loop.
*****/
class for2 { //define the controlling class
  public static void main(String[] args){ //main method

    for(int cnt = 0; cnt < 2; cnt++)
      System.out.println(
        "Value of loop var named cnt is " + cnt);

    System.out.println(
      "Value of method var named cnt is " + cnt);
  } //end main
} //End controlling class. Note no semicolon required

```

Table 2.72

The declaration of the variable named `cnt`, outside the `for` loop, was removed from Listing 3 (p. 191) and the declaration inside the loop was allowed to remain. This eliminated the problem of attempting to declare the variable twice.

However, this program refused to compile because an attempt was made to access the variable named `cnt` outside the `for` loop. This was not allowed because the variable was declared inside the `for` loop and the scope of the variable was limited to the loop.

This program will compile

The Java program shown in Listing 4 (p. 191) will compile and run because the variable named `cnt` that is declared inside the `for` loop is accessed only inside the `for` loop. No reference to a variable with the same name appears outside the loop.

Listing 4 . A program that will compile.

```

/*File for3.java Copyright 1997, R.G.Baldwin
This program will compile because the variable declared
inside the for loop is accessed only inside the loop.
*****/
class for3 { //define the controlling class
  public static void main(String[] args){ //main method

    for(int cnt = 0; cnt < 2; cnt++)
      System.out.println(
        "Value of loop var named cnt is " + cnt);
  } //end main
} //End controlling class.

```

Table 2.73

This program will also compile

Similarly, the program shown in Listing 5 (p. 192) will compile and run because the variable named **cnt** was declared outside the **for** loop and was not declared inside the **for** loop. This made it possible to access that variable both inside and outside the loop.

Listing 5 . Another program that will compile.

```

/*File for4.java Copyright 1997, R.G.Baldwin
This program will compile and run because the variable
named cnt is declared outside the for loop and is not
declared inside the for loop.
*****/
class for4 { //define the controlling class
  public static void main(String[] args){ //main method
    int cnt = 5; //declare local method variable
    System.out.println(
      "Value of method var named cnt is " + cnt);

    for(cnt = 0; cnt < 2; cnt++)
      System.out.println(
        "Value of loop var named cnt is " + cnt);

    System.out.println(
      "Value of method var named cnt is " + cnt);
  } //end main
} //End controlling class. Note no semicolon required

```

Table 2.74

Empty clauses in a *for* loop

The first and third clauses in a **for** loop can be left empty but the semicolons must be there as placeholders.

One author suggests that even the middle clause can be empty, but it isn't obvious to this author how the loop would ever terminate if there is no conditional expression to be evaluated. Perhaps the loop could be terminated by using a **break** inside the loop, but in that case, you might just as well use a **while** loop.

2.28.4.5 The for-each loop

There is another form of loop structure that is often referred to as a **for-each** loop. In order to appreciate the benefits of this loop structure, you need to be familiar with Java collections and iterators, both of which are beyond the scope of this module.

As near as I can tell, there is nothing that you can do with the **for-each** loop that you cannot also do with the conventional **for** loop described above. Therefore, I rarely use it. You can find a description of the **for-each** loop on this Oracle website ¹³⁹.

I don't plan to discuss it further in this module. However, before you go for a job interview, you should probably do some online research and learn about it because an interviewer could use a question about the **for-each** loop to trip you up in the Q and A portion of the interview.

¹³⁹<http://docs.oracle.com/javase/1.5.0/docs/guide/language/foreach.html>

2.28.4.6 The do-while loop

The **do-while** loop is another implementation of the *loop* pillar mentioned earlier (p. 186) . However, it differs from the **while** loop and the **for** loop in one important respect; it is an *exit-condition* loop.

An exit-condition loop

Java provides an *exit-condition* loop having the syntax shown in Figure 6 (p. 193) .

Figure 6 . Syntax of a do-while loop.

```
do {
    statements
} while (conditional expression);
```

Table 2.75

Behavior

The statements in the body of the loop continue to be executed for as long as the conditional expression evaluates to true. An exit-condition loop guarantees that the body of the loop will be executed at least one time, even if the conditional expression evaluates to false the first time it is tested.

2.28.4.7 The break and continue statements

General behavior

Although some authors suggest that the **break** and **continue** statements provide an alternative to the infamous **goto** statement of earlier programming languages, it appears that the behaviors of the **labeled break** and **labeled continue** statements are much more restrictive than a general **goto** .

2.28.4.8 Unlabeled break and continue

The **break** and **continue** statements are supported in both labeled and unlabeled form.

First consider the behavior of break and continue in their unlabeled configuration.

Use of a *break* statement

The **break** statement can be used in a switch statement or in a loop. When encountered in a switch statement, break causes control to be passed to the next statement outside the innermost enclosing switch statement.

When break is encountered in a loop, it causes control to be passed to the next statement outside the innermost enclosing loop.

As you will see later, labeled break statements can be used to pass control to the next statement following switch or loop statements beyond the innermost switch or loop statement when those statements are nested.

Use of a *continue* statement

The continue statement cannot be used in a switch statement, but can be used inside a loop.

When an unlabeled continue statement is encountered, it causes the current iteration of the current loop to be terminated and the next iteration to begin.

A labeled continue statement can cause control to be passed to the next iteration of an outer enclosing loop in a nested loop situation.

An example of the use of an unlabeled switch statement is given in the next section.

2.28.4.9 Labeled break and continue statements

This section discusses the use of labeled break and continue statements.

2.28.4.9.1 Labeled break Statements

One way to describe the behavior of a labeled break in Java is to say: "Break all the way out of the labeled statement."

Syntax of a labeled statement

To begin with, the syntax of a labeled statement is a label followed by a colon ahead of the statement as shown in Figure 7 (p. 194) .

Figure 7 . Syntax of a labeled statement.

```
myLabel: myStatement;
```

Table 2.76

The label can be any legal Java identifier.

Behavior of labeled break

The behavior of a labeled break can best be illustrated using nested switch statements. For a comparison of labeled and unlabeled switch statements, consider the program shown in Listing 6 (p. 195) named **switch1** , which does not use a labeled break. Even though this program has a labeled statement, that statement is not referenced by a **break** . Therefore, the label is of no consequence.

Listing 6 . The program named switch1.java.

```

/*File switch1.java
This is a Java application which serves as a baseline
comparison for switch2.java which uses a labeled break.
Note that the program uses nested switch statements.

The program displays the following output:

Match and break from here
Case 6 in outer switch
Default in outer switch
Beyond switch statements

*****/
class switch1 { //define the controlling class
    public static void main(String[] args){ //main method

        //Note that the following labeled switch statement is
        // not referenced by a labeled break in this program.
        // It will be referenced in the next program.
        outerSwitch: switch(5){//labeled outer switch statement
            case 5: //execute the following switch statement
                //Note that the code for this case is not followed
                // by break. Therefore, execution will fall through
                // the case 6 and the default.
                switch(1){ //inner switch statement
                    case 1: System.out.println(
                        "Match and break from here");
                        break; //break with no label
                    case 2: System.out.println(
                        "No match for this constant");
                        break;
                }//end inner switch statement

            case 6: System.out.println("Case 6 in outer switch");
            default: System.out.println(
                "Default in outer switch");
        }//end outer switch statement

        System.out.println("Beyond switch statements");
    }//end main
} //End switch1 class.

```

Table 2.77

After reviewing **switch1.java** , consider the same program named **switch2.java** shown in Listing 7 (p. 196) , which was modified to use a labeled break.

The outputs from both programs are shown in the comments at the beginning of the program. By examining the second program, and comparing the output from the second program with the first program,

you should be able to see how the use of the labeled break statement causes control to break all the way out of the labeled switch statement.

Listing 7 . The program named switch2.java.

```

/*File switch2.java
This is a Java application which uses a labeled break.
Note that the program uses nested switch statements.

See switch1.java for a comparison program which does not
use a labeled break.

The program displays the following output:

Match and break from here
Beyond switch statements
*****/
class switch2 { //define the controlling class
    public static void main(String[] args){ //main method

        outerSwitch: switch(5){//labeled outer switch statement
            case 5: //execute the following switch statement
                //Note that the code for this case is not followed by
                // break. Therefore, except for the labeled break at
                // case 1, execution would fall through the case 6 and
                // the default as demonstrated in the program named
                // switch1. However, the use of the labeled break
                // causes control to break all the way out of the
                // labeled switch bypassing case 6 and the default.
                switch(1){ //inner switch statement
                    case 1: System.out.println(
                        "Match and break from here");
                        break outerSwitch; //break with label
                    case 2: System.out.println(
                        "No match for this constant");
                        break;
                }//end inner switch statement

            case 6: System.out.println(
                "Case 6 in outer switch");
            default: System.out.println("Default in outer switch");
        }//end outer switch statement

        System.out.println("Beyond switch statements");
    }//end main
} //End switch1 class.

```

Table 2.78

The modified program in Listing 7 (p. 196) uses a labeled break statement in the code group for *case 1* whereas the original program in Listing 6 (p. 195) has an unlabeled break in that position.

By comparing the output from this program with the output from the previous program, you can see that execution of the labeled break statement caused control to break all the way out of the labeled switch statement completely bypassing *case 6* and default.

As you can see from examining the output, the labeled break statement causes the program to break all the way out of the switch statement which bears a matching label.

A similar situation exists when a labeled break is used in nested loops with one of the enclosing outer loops being labeled. Control will break out of the enclosing loop to which the labeled break refers. It will be left as an exercise for the student to demonstrate this behavior to his or her satisfaction.

2.28.4.9.2 Labeled continue statements

Now consider use of the labeled continue statement. A **continue** statement can only be used in a loop; it cannot be used in a switch. The behavior of a labeled continue statement can be described as follows: "Terminate the current iteration and continue with the next iteration of the loop to which the label refers."

Again, it will be left as an exercise for the student to demonstrate this behavior to his or her satisfaction.

2.28.4.10 The return statement

Use of the return statement

Java supports the use of the **return** statement to terminate a method and (*optionally*) return a value to the calling method.

The return type

The type of value returned must match the type of the declared return value for the method.

The void return type

If the return value is declared as **void**, you can use the syntax shown in Figure 8 (p. 197) to terminate the method. (*You can also simply allow the method to run out of statements to execute.*)

Figure 8 . An empty return statement.

```
return;
```

Table 2.79

Returning a value

If the method returns a value, follow the word return with an expression (*or constant*) that evaluates to the value being returned as shown in Figure 9 (p. 197).

Figure 9 . Returning a value from a method.

```
return x+y;
```

Table 2.80

Return by value only

You are allowed to return only by *value* . In the case of primitive types, this returns a copy of the returned item. In the case of objects, returning by value returns a copy of the object's reference.

What you can do with a copy the object's reference

Having a copy of the reference is just as good as having the original reference. A copy of the reference gives you access to the object.

When Java objects are destroyed

All objects in Java are stored in dynamic memory and that memory is not overwritten until all references to that memory cease to exist.

Java uses a garbage collector running on a background thread to reclaim memory from objects that have become *eligible for garbage collection* .

An object becomes eligible for garbage collection when there are no longer any variables, array elements, or similar storage locations containing a reference to the object. In other words, it becomes eligible when there is no way for the program code to find a reference to the object.

2.28.4.11 Exception handling

Exception handling is a process that modifies the flow of control of a program, so it merits being mentioned in this module. However, it is a fairly complex topic, which will be discussed in detail in future modules.

Suffice it at this point to say that whenever an exception is detected, control is transferred to exception handler code if such code has been provided. Otherwise, the program will terminate. Thus, the exception handling system merits being mentioned in discussions regarding flow of control.

2.29.4 Answers

2.29.4.1 Answer 21

True.

Back to Question 21 (p. 202)

2.29.4.2 Answer 20

True.

Back to Question 20 (p. 202)

2.29.4.3 Answer 19

False. Although the third clause appears physically at the top of the loop, it isn't executed until the statements in the body of the loop have completed execution. This is an important point since this clause is typically used to update the control variable, and perhaps other variables as well. If variables are updated in the third clause and used in the body of the loop, it is important to understand that they do not get updated until the execution of the body is completed.

Back to Question 19 (p. 202)

2.29.4.4 Answer 18

False. The value of the second clause is tested when the statement first begins execution, and at the beginning of each iteration thereafter. Therefore, the **for** loop is an *entry condition* loop.

Back to Question 18 (p. 202)

2.29.4.5 Answer 17

False. The second clause consists of a single expression which must eventually evaluate to false (*not true*) to cause the loop to terminate.

Back to Question 17 (p. 202)

2.29.4.6 Answer 16

True.

Back to Question 16 (p. 202)

2.29.4.7 Answer 15

Typically the first clause is used for initialization. The intended purpose of the first clause is initialization.

Back to Question 15 (p. 202)

2.29.4.8 Answer 14

False. The expressions in the first clause are executed only once, at the beginning of the loop, regardless of the number of iterations.

Back to Question 14 (p. 202)

2.29.4.9 Answer 13

The *comma operator* guarantees that its left operand will be executed before its right operand.

Back to Question 13 (p. 201)

2.29.4.10 Answer 12

True.

Back to Question 12 (p. 201)

2.29.4.11 Answer 11

The general syntax of a `for` loop follows:

Syntax of a for loop

```
for (first clause; second clause; third clause)
    single or compound statement
```

Back to Question 11 (p. 201)

2.29.4.12 Answer 10

False: A `for` loop header consists of three clauses separated by semicolons, not colons.

Back to Question 10 (p. 201)

2.29.4.13 Answer 9

The operation of a loop normally involves the following three actions in addition to executing the code in the body of the loop:

- Initialize a control variable.
- Test the control variable in a conditional expression.
- Update the control variable.

Back to Question 9 (p. 201)

2.29.4.14 Answer 8

The pseudo-code fragment follows:

Syntax of a switch-case statement

```
switch(expression){
    case constant:
        sequence of optional statements
        break; //optional
    case constant:
        sequence of optional statements
        break; //optional
    .
    .
    .
    default //optional
        sequence of optional statements
}
```

An expression is tested against a series of unique integer constants. If a match is found, the sequence of optional statements associated with the matching constant is executed. Execution of statements continues until an optional **break** is encountered. When **break** is encountered, execution of the **switch** statement is terminated and control is passed to the next statement following the **switch** statement.

If no match is found and the optional **default** keyword along with a sequence of optional statements has been provided, those statements will be executed.

Back to Question 8 (p. 201)

2.29.4.15 Answer 7

The general syntax of the **switch-case** statement follows:

Syntax of a switch-case statement

```
switch(expression){
  case constant:
    sequence of optional statements
    break; //optional
  case constant:
    sequence of optional statements
    break; //optional
  .
  .
  .
  default //optional
    sequence of optional statements
}
```

Back to Question 7 (p. 201)

2.29.4.16 Answer 6

The general syntax of the if-else statement is:

Syntax of an if-else statement

```
if(conditional expression)
  statement or compound statement;
else //optional
  statement or compound statement; //optional
```

Back to Question 6 (p. 201)

2.29.4.17 Answer 5

The significance of an *entry condition* loop is that the conditional expression is tested before the statements in the loop are executed. If it tests false initially, the statements in the loop will not be executed.

Back to Question 5 (p. 201)

2.29.4.18 Answer 4

True.

Back to Question 4 (p. 201)

2.29.4.19 Answer 3

True. Note however that including a **return** statement inside a **while** statement is probably considered poor programming practice.

Back to Question 3 (p. 200)

2.29.4.20 Answer 2

The general syntax of a **while** statement follows :

Syntax of a while statement

```
while (conditional expression)
    statement or compound statement;
```

Back to Question 2 (p. 200)

2.29.4.21 Answer 1

The following table lists the statements supported by Java for controlling the logical flow of the program.

2.30.3 Introduction

The first step

The first step in learning to use a new programming language is usually to learn the foundation concepts such as variables, types, expressions, flow-of-control, arrays, strings, etc. This module concentrates on arrays and strings.

Array and String types

Java provides a type for both arrays and strings from which objects of the specific type can be instantiated. Once instantiated, the methods belonging to those types can be called by way of the object.

2.30.4 Arrays

Arrays and Strings

Java has a true array type and a true **String** type with protective features to prevent your program from writing outside the memory bounds of the array object or the **String** object. Arrays and strings are true objects.

Declaring an array

You must declare an array before you can use it. (*More properly, you must declare a reference variable to hold a reference to the array object.*) In declaring the array, you must provide two important pieces of information:

¹⁵⁰<http://cnx.org/content/m44199>

¹⁵¹<http://cnx.org/content/m44200>

- the name of a variable to hold a reference to the array object
- the type of data to be stored in the elements of the array object

Different declaration formats

A reference variable capable of holding a reference to an array object can be declared using either format shown in Figure 1 (p. 210) . *(I personally prefer the first option because I believe it is more indicative of the purpose of the declaration. However, both options produce the same result – a reference variable capable of storing a reference to an array object.)*

Figure 1 . Formats for declaring a reference variable for an array object.
<pre>int[] myArray; int myArray[];</pre>

Table 2.81

Declaration does not allocate memory

As with other objects, the declaration of the reference variable does not allocate memory to contain the array data. Rather it simply allocates memory to contain a reference to the array.

Allocating memory for the array object

Memory to contain the array object must be allocated from dynamic memory using statements such as those shown in Figure 2 (p. 210) .

Figure 2 . Allocating memory for the array object.
<pre>int[] myArrayX = new int[15]; int myArrayY[] = new int[25]; int[] myArrayZ = {3,4,5};</pre>

Table 2.82

The statements in Figure 2 (p. 210) simultaneously declare the reference variable and cause memory to be allocated to contain the array.

Also note that the last statement in Figure 2 (p. 210) is different from the first two statements. This syntax not only sets aside the memory for the array object, the elements in the array are initialized by evaluating the expressions shown in the coma-separated list inside the curly brackets.

On the other hand, the array elements in the first two statements in Figure 2 (p. 210) are automatically initialized with the default value for the type.

Declaration and allocation can be separated

It is not necessary to combine these two processes. You can execute one statement to declare the reference variable and another statement to cause the array object to be instantiated some time later in the program as shown in Figure 3 (p. 211) .

Figure 3 . Declaration and instantiation can be separated.

```
int[] myArray;
. . .
myArray = new int[25];
```

Table 2.83

Causing memory to be set aside to contain the array object is commonly referred to as instantiating the array object (*creating an instance of the array object*) .

If you prefer to declare the reference variable and instantiate the array object at different points in your program, you can use the syntax shown in Figure 3 (p. 211) . This pattern is very similar to the declaration and instantiation of all objects.

General syntax for combining declaration and instantiation

The general syntax for declaring and instantiating an array object is shown in Figure 4 (p. 211) .

Figure 4 . General syntax for combining declaration and instantiation.

```
typeOfElements[] nameOfRefVariable =
    new typeOfElements[sizeOfArray]
```

Table 2.84

Accessing array elements

Having instantiated an array object, you can access the elements of the array using indexing syntax that is similar to many other programming languages. An example is shown in Figure 5 (p. 211) .

Figure 5 . An example of array indexing syntax.

```
myArray[5] = 6;
myVar = myArray[5];
```

Table 2.85

The value of the first index

Array indices always begin with 0.

The length property of an array

The code fragment in Figure 6 (p. 212) illustrates another interesting aspect of arrays. (*Note the use of **length** in the conditional clause of the **for** loop.*)

Figure 6 . The use of the length property in the conditional clause of a for loop.

```
for(int cnt = 0; cnt < myArray.length; cnt++)
    myArray[cnt] = cnt;
```

Table 2.86

All array objects have a **length** property that can be accessed to determine the number of elements in the array. (*The number of elements cannot change once the array object is instantiated.*)

Types of data that you can store in an array object

Array elements can contain any Java data type including primitive values and references to ordinary objects or references to other array objects.

Constructing multi-dimensional arrays

All array objects contains a one-dimensional array structure. You can create multi-dimensional arrays by causing the elements in one array object to contain references to other array objects. In effect, you can create a tree structure of array objects that behaves like a multi-dimensional array.

Odd-shaped multi-dimensional arrays

The program **array01** shown in Listing 1 (p. 213) illustrates an interesting aspect of Java arrays. Java can produce multi-dimensional arrays that can be thought of as an array of arrays. However, the secondary arrays need not all be of the same size.

In the program shown in Listing 1 (p. 213) , a two-dimensional array of integers is declared and instantiated with the primary size (*size of the first dimension*) being three. The sizes of the secondary dimensions (*sizes of each of the sub-arrays*) is 2, 3, and 4 respectively.

Can declare the size of secondary dimension later

When declaring a *"two-dimensional"* array, it is not necessary to declare the size of the secondary dimension when the primary array is instantiated. Declaration of the size of each sub-array can be deferred until later as illustrated in this program.

Accessing an array out-of-bounds

This program also illustrates the result of attempting to access an element that is out-of-bounds. Java protects you from such programming errors.

ArrayIndexOutOfBoundsException

An exception occurs if you attempt to access out-of-bounds, as shown in the program in in Listing 1 (p. 213) .

In this case, the exception was simply allowed to cause the program to terminate. The exception could have been caught and processed by an exception handler, a concept that will be explored in a future module.

The program named array01

The entire program is shown in Listing 1 (p. 213) . The output from the program is shown in the comments at the top of the listing.

Listing 1 . The program named array01.

Table 2.87**Assigning one array to another array – be careful**

Java allows you to assign one array to another. You must be aware, however, that when you do this, you are simply making another copy of the reference to the same data in memory.

Then you simply have two references to the same data in memory, which is often not a good idea. This is illustrated in the program named **array02** shown in Listing 2 (p. 215) .

Listing 2 . The program named array02 .

2.30.5 Arrays of Objects

An array of objects really isn't an array of objects

There is another subtle issue that you need to come to grips with before we leave our discussion of arrays. In particular, when you create an array of objects, it really isn't an array of objects.

Rather, it is an array of object references (*or null*) . When you assign primitive values to the elements in an array object, the actual primitive values are stored in the elements of the array.

However, when you assign objects to the elements in an array , the actual objects aren't actually stored in the array elements. Rather, the objects are stored somewhere else in memory. The elements in the array contain references to those objects.

All the elements in an array of objects need not be of the same actual type

The fact that the array is simply an array of reference variables has some interesting ramifications. For example, it isn't necessary that all the elements in the array be of the same type, provided the reference variables are of a type that will allow them to refer to all the different types of objects.

For example, if you declare the array to contain references of type **Object** , those references can refer to any type of object (*including array objects*) because a reference of type **Object** can be used to refer to any object.

You can do similar things using *interface* types. I will discuss interface types in a future module.

Often need to downcast to use an Object reference

If you store all of your references as type **Object** , you will often need to downcast the references to the true type before you can use them to access the instance variables and instance methods of the objects.

Doing the downcast no great challenge as long as you can decide what type to downcast them to.

The Vector class

There is a class named **Vector** that takes advantage of this capability. An object of type **Vector** is a self-expanding array of reference variables of type **Object** . You can use an object of type **Vector** to manage a group of objects of any type, either all of the same type, or mixed.

(Note that you cannot store primitive values in elements of a non-primitive or reference type. If you need to do that, you will need to wrap your primitive values in an object of a wrapper class as discussed in an earlier module.)

A sample program using the Date class

The sample program, named **array03** and shown in Listing 3 (p. 217) isn't quite that complicated. This program behaves as follows:

- Declare a reference variable to an array of type **Date** . *(The actual type of the variable is Date[].)*
- Instantiate a three-element array of reference variables of type **Date** .
- Display the contents of the array elements and confirm that they are all null as they should be. *(When created using this syntax, new array elements contain the default value, which is null for reference types.)*
- Instantiate three objects of type **Date** and store the references to those objects in the three elements of the array.
- Access the references from the array and use them to display the contents of the individual **Date** objects.

As you might expect from the name of the class, each object contains information about the date.

Listing 3 . The program named Array03 .

```

Illustrates that "an array of objects" is not really an
array of objects, but rather is an array of references
to objects. The objects are not stored in the array,
but rather are stored somewhere else in memory and the
references in the array elements refer to them.

The output from running this program is:

            System.out.println(this.myArrayOfRefs[cnt]);
        System.out.println();

        //Instantiate three objects and assign references to
        // those three objects to the three reference
        // variables in the array.

            myArrayOfRefs[cnt] = new Date();

        System.out.println();
    } //end main

2.30.6 Strings

What is a string?

A string is commonly considered to be a sequence of characters stored in memory and accessible as a unit.

Java implements strings using the **String** class and the **StringBuffer** class.

What is a string literal?

Java considers a series of characters surrounded by quotation marks as shown in Figure 7 (p. 218) to be a string literal.

Figure 7 . A string literal.
"This is a string literal in Java."

Table 2.90

This is just an introduction to strings

A major section of a future module will be devoted to the topic of strings, so this discussion will be brief.

String objects cannot be modified

String objects cannot be changed once they have been created. (*They are said to be immutable.*) If you have that need, use the **StringBuffer** class instead.

StringBuffer objects can be used to create and manipulate character data as the program executes.

2.30.6.1 String Concatenation

Java supports string concatenation using the overloaded + operator as shown in Figure 8 (p. 218) .

Figure 8 . String concatenation.
"My variable has a value of " + myVar + " at this point in the program."

Table 2.91

Coercion of an operand to type String

The overloaded + operator is used to concatenate strings. If either operand is type **String** , the other operand is coerced into type **String** and the two strings are concatenated.

Therefore, in addition to concatenating the strings, Java also converts values of other types, such as **myVar** in Figure 8 (p. 218) , to character-string format in the process.

2.30.6.2 Arrays of String References

Declaring and instantiating a String array

The statement in Figure 9 (p. 220) declares and instantiates an array of references to five **String** objects.

Figure 9 . Declaring and instantiating a String array.

```
String[] myArrayOfStringReferences = new String[5];
```

Table 2.92**No string data at this point**

Note however, that this array doesn't contain the actual **String** objects. Rather, it simply sets aside memory for storage of five references of type **String** . (*The array elements are automatically initialized to null.*) No memory has been set aside to store the characters that make up the individual **String** objects. You must allocate the memory for the actual **String** objects separately using code similar to the code shown in Figure 10 (p. 220) .

Figure 10 . Allocating memory to contain the String objects.

```
myArrayOfStringReferences[0] = new String(
    "This is the first string.");
myArrayOfStringReferences[1] = new String(
    "This is the second string.");
```

Table 2.93**The new operator is not required for String class**

Although it was used in Figure 10 (p. 220) , the **new** operator is not required to instantiate an object of type **String** . I will discuss the ability of Java to instantiate objects of type **String** without the requirement to use the **new** operator in a future module.

2.30.7 Run the programs

I encourage you to copy the code from Listing 1 (p. 213) , Listing 2 (p. 215) , and Listing 3 (p. 217) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

2.31.5.1 Answer 18

Listing 1 . Listing for Answer 18.

```

class SampProg10 { //define the controlling class
  public static void main(String[] args){ //define main
    //Declare a two-dimensional array with a size of 3 on
    // the primary dimension but with different sizes on
    // the secondary dimension.
    //Secondary size not specified
    int[][] myArray = new int[3][];
    myArray[0] = new int[2]; //secondary size is 2
    myArray[1] = new int[3]; //secondary size is 3
    myArray[2] = new int[4]; //secondary size is 4

    //Fill the array with data
    for(int i = 0; i < 3; i++){
      for(int j = 0; j < myArray[i].length; j++){
        myArray[i][j] = i * j;
      } //end inner loop
    } //end outer loop

    //Display data in the array
    for(int i = 0; i < 3; i++){
      for(int j = 0; j < myArray[i].length; j++){
        System.out.print(myArray[i][j]);
      } //end inner loop
      System.out.println();
    } //end outer loop

    //Attempt to access an out-of-bounds array element
    try{
      System.out.println(
        "Attempt to access array out of bounds");

Back to Question 18 (p. 224)

2.31.5.2 Answer 17

The following statement declares and instantiates an array object capable of storing references to two **String** objects.

```
String[] myArrayOfStringReferences = new String[2];
```

Note however, that this array object doesn't contain the actual string data. Rather, it simply sets aside memory for storage of two references to **String** objects. No memory has been set aside to store the characters that make up the individual strings. You must allocate the memory for the actual **String** objects separately using code similar to the following.

```
myArrayOfStringReferences[0] = new String(  
    "This is the first string.");  
myArrayOfStringReferences[1] = new String(  
    "This is the second string.");
```

Back to Question 17 (p. 224)

2.31.5.3 Answer 16

Java supports string concatenation using the overloaded + operator as shown in the following code fragment:

```
"My variable has a value of " + myVar +  
" at this point in the program."
```

Back to Question 16 (p. 224)

2.31.5.4 Answer 15

String objects cannot be modified once they have been created. **StringBuffer** objects can be modified
Back to Question 15 (p. 224)

2.31.5.5 Answer 14

The Java compiler considers a series of characters surrounded by quotation marks to be a literal string, as in the following code fragment:

```
"This is a literal string in Java."
```

Back to Question 14 (p. 224)

2.31.5.6 Answer 13

A string is commonly considered to be a sequence of characters stored in memory and accessible as a unit. Java implements strings using the **String** class and the **StringBuffer** class.

Back to Question 13 (p. 224)

2.31.5.7 Answer 12

Java allows you to assign one array to another. When you do this, you are simply making another copy of the reference to the same data in memory. Then you have two references to the same data in memory. This is illustrated in the program named **array02.java** in Jb0240: Java OOP: Arrays and Strings ¹⁶¹ .

Back to Question 12 (p. 223)

2.31.5.8 Answer 11

False. When declaring a two-dimensional array, it is not necessary to declare the size of the secondary dimension when the array is declared. Declaration of the size of each sub-array can be deferred until later as illustrated in the program named **array01.java** in Jb0240: Java OOP: Arrays and Strings ¹⁶² .

Back to Question 11 (p. 223)

2.31.5.9 Answer 10

False. Java can be used to produce multi-dimensional arrays that can be viewed as an array of arrays. However, the secondary arrays need not all be of the same size. See the program named **array01.java** in Jb0240: Java OOP: Arrays and Strings ¹⁶³ .

Back to Question 10 (p. 223)

2.31.5.10 Answer 9

Array objects can contain any Java data type including primitive values, references to ordinary objects, and references to other array objects.

Back to Question 9 (p. 223)

2.31.5.11 Answer 8

All array objects have a **length** property that can be accessed to determine the number of elements in the array as shown below.

```
for(int cnt = 0; cnt < myArray.length; cnt++)
    myArray[cnt] = cnt;
```

Back to Question 8 (p. 223)

2.31.5.12 Answer 7

False. Array indices always begin with 0.

¹⁶²<http://cnx.org/content/m45214>

¹⁶³<http://cnx.org/content/m45214>

2.31.5.13 Answer 6

False. While it is possible to simultaneously declare the name of the variable and cause memory to be allocated to contain the array object, it is not necessary to combine these two processes. You can execute one statement to declare the variable and another statement to cause the memory for the array object to be allocated as shown below.

```
int[] myArray;  
.  
.  
.  
myArray = new int[25];
```

Back to Question 6 (p. 223)

2.31.5.14 Answer 5

False. As with other objects, the declaration of the variable does not allocate memory to contain the array object. Rather it simply allocates memory to contain a reference to the array object. Memory to contain the array object must be allocated from dynamic memory using statements such as the following.

```
int[] myArray = new int[15];  
int myArray[] = new int[25];  
int[] myArray = {1,2,3,4,5}
```

Back to Question 5 (p. 223)

2.31.5.15 Answer 4

```
int[] myArray;  
int myArray[];
```

Back to Question 4 (p. 222)

2.31.5.16 Answer 3

In declaring the variable, you must provide two important pieces of information:

- the name of the variable
- the type of the variable, which indicates the type of data to be stored in the array

Back to Question 3 (p. 222)

2.31.5.17 Answer 2

False. Java has a true array type and a true **String** type with protective features to prevent your program from writing outside the memory bounds of the array or the **String** .

Back to Question 2 (p. 222)

2.31.5.18 Answer 1

True.

2.32.2 Preface

This module provides a very brief treatment of exception handling. The topic is discussed in detail in the module titled Java OOP: Exception Handling¹⁶⁷. The topic is included in this *Programming Fundamentals* section simply to introduce you to the concept.

2.32.2.1.1 Listings

- Listing 1 (p. 232) . The program named simple1.

2.32.3 Discussion

What is an exception?

According to The Java Tutorials¹⁶⁸, "*An exception is an event that occurs during the execution of a program that disrupts the normal flow of instructions.*"

A very common example of an exception given in textbooks is code that attempts to divide by zero (*this is easy to demonstrate*) .

Throwing an exception

Common terminology states that when this happens, the system *throws an exception* . If a thrown exception is not *caught* , a runtime error may occur.

Purpose of exception handling

The purpose of exception handling is to make it possible for the program to either attempt to recover from the problem, or at worst shut down the program in a graceful manner, whenever an exception occurs.

Java supports exception handling

Java, C++, and some other programming languages support exception handling in similar ways.

In Java, the exception can be thrown either by the system or by code created by the programmer. There is a fairly long list of exceptions that will be thrown automatically by the Java runtime system.

Checked exceptions cannot be ignored

Included in that long list of automatic exceptions is a subset known as "checked" exceptions. Checked exceptions cannot be ignored by the programmer. A method must either specify (*declare*) or catch all "checked" exceptions that can be thrown in order for the program to compile.

An example of specifying an exception

I explain the difference between specifying and catching an exception in Java OOP: Exception Handling¹⁶⁹ . For now, suffice it to say that the code that begins with the word "throws" in Listing 1 (p. 232)

¹⁶⁷<http://cnx.org/content/m44202>

¹⁶⁸<http://docs.oracle.com/javase/tutorial/essential/exceptions/>

¹⁶⁹<http://cnx.org/content/m44202>

specifies (*declares*) an exception that can be thrown by the code inside the **main** method.

If this specification is not made, the program will not compile.

Listing 1 . The program named simple1.

```

/*File simple1.java Copyright 1997, R.G.Baldwin
*****
class simple1 { //define the controlling class
    public static void main(String[] args)
        throws java.io.IOException {
        int ch1, ch2 = '0';

        System.out.println(
            "Enter some text, terminate with #");

        //Get and save individual bytes
        while( (ch1 = System.in.read() ) != '#') ch2 = ch1;

        //Display the character immediately before the #
        System.out.println("The char before the # was "
            + (char)ch2);
    } //end main
} //End simple1 class.

```

Table 2.95

The program in Listing 1 (p. 232) does not throw any exceptions directly nor does it attempt to catch any exceptions. However, it can throw exceptions indirectly through its call to **System.in.read** .

Because **IOException** is a checked exception, the **main** method must either specify it or catch it . Otherwise the program won't compile. In this case, the **main** method specifies the exception as opposed to catching it.

Very brief treatment

As mentioned earlier, this is a very brief treatment of a fairly complex topic that is discussed in much more detail in the module titled Java OOP: Exception Handling¹⁷⁰ . The topic was included at this point simply to introduce you to the concept of exceptions.

2.32.4 Run the program

2.33.2 Preface

Although the use of command-line arguments is rare in this time of Graphical User Interfaces (*GUI*), they are still useful for testing and debugging code. This module explains the use of command-line arguments in Java.

2.33.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following link to easily find and view the listing while you are reading about it.

2.33.2.1.1 Listings

- Listing 1 (p. 235) . Illustration of command-line arguments.

2.33.3 Discussion

Familiar example from DOS

Java programs can be written to accept command-line-arguments. DOS users will be familiar with commands such as the following:

Familiar DOS command

```
copy fileA fileB
```

In this case, **copy** is the name of the program to be executed, while **fileA** and **fileB** are command-line arguments.

Java syntax for command-line arguments

The Java syntax for supporting command-line arguments is shown below (*note the formal argument list for the **main** method*) .

Java syntax for command-line arguments

```
public static void main(String[] args){
    . . .
} //end main method
```

In Java, the formal argument list for the **main** method must appear in the method signature whether or not the program is written to support the use of command-line arguments. If the argument isn't used, it is simply ignored.

Where the arguments are stored

The parameter **args** contains a reference to a one-dimensional array object of type **String** .

Each of the elements in the array (*including the element at index zero*) contains a reference to an object of type **String** . Each object of type **String** encapsulates one command-line argument.

The number of arguments entered by the user

Recall from an earlier module on arrays that the number of elements in a Java array can be obtained from the **length** property of the array. Therefore, the number of arguments entered by the user is equal to the value of the **length** property. If the user didn't enter any arguments, the value will be zero.

Command-line arguments are separated by the space character. If you need to enter an argument that contains a space, surround the entire argument with quotation mark characters as in *"My command line argument"* .

The first command-line argument is encapsulated in the **String** object referred to by the contents of the array element at index 0, the second argument is referred to by the element at index 1, etc.

Sample Java program

The sample program in Listing 1 (p. 235) illustrates the use of command-line arguments.

Listing 1 . Illustration of command-line arguments.

```

/*File cmdlin01.java Copyright 1997, R.G.Baldwin
This Java application illustrates the use of Java
command-line arguments.

When this program is run from the command line as follows:

java cmdlin01 My command line arguments

the program produces the following output:

My
command
line
arguments
*****/
class cmdlin01 { //define the controlling class
    public static void main(String[] args){ //main method
        for(int i=0; i < args.length; i++)
            System.out.println( args[i] );
        }//end main
    }//End cmdlin01 class.

```

Table 2.96

The output from running this program for a specific input is shown in the comments at the beginning of the program.

2.33.4 Run the program

I encourage you to copy the code Listing 1 (p. 235) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

Each of the elements in the array object referred to by **args** (*including the element at position zero*) contains a reference to a **String** object that encapsulates one of the command-line arguments.

2.34.5.4 Answer 3

True.

Back to Question 3 (p. 237)

2.34.5.5 Answer 2

Command-line-arguments are used in many programming and computing environments to provide information to the program at startup that it will need to fulfill its mission during that particular invocation.

Back to Question 2 (p. 237)

2.34.5.6 Answer 1

DOS users will be familiar with commands such as the following:

Command-line arguments in DOS

```
copy fileA fileB
```

In this case, **copy** is the name of the program to be executed, while **fileA** and **fileB** are command-line arguments.

2.35.3 Introduction

Before you can understand much about packages, you will need to understand the *classpath environment variable* , so that is where I will begin the discussion.

After learning about the classpath environment variable, you will learn how to create your own packages.

2.35.4 Classpath environment variable

The purpose of the *classpath environment variable* is to tell the JVM and other Java applications (*such as the javac compiler*) where to find class files and class libraries. This includes those class files that are part of the JDK and class files that you may create yourself.

I am assuming that you already have some familiarity with the use of environment variables in your operating system. All of the discussion in this module will be based on the use of a generic form of Windows. (*By generic, I mean not tied to any particular version of Windows.*) Hopefully you will be able to translate the information to your operating system if you are using a different operating system.

In a nutshell Environment variables provide information that the operating system uses to do its job.

There are usually a fairly large number of environment variables installed on a machine at any give time. If you would like to see what kind of environment variables are currently installed on your machine, bring up a command-line prompt and enter the command `set` . This should cause the names of several environment variables, along with their settings to be displayed on your screen.

While you are at it, see if any of those items begin with `CLASSPATH=` . If so, you already have a classpath environment variable set on your machine, but it may not contain everything that you need.

I am currently using a Windows 7 operating system and no classpath environment variable is set on it. I tend to use the `-cp` switch option (*see Listing 4 (p. 249)*) in the JDK to set the classpath on a temporary basis when I need it to be set.

Rather than trying to explain all of the ramifications regarding the classpath, I will simply refer you to an Oracle document on the topic titled *Setting the class path* ¹⁸⁵ .

I will also refer you to *Java OOP: The Guzdial-Ericson Multimedia Class Library* ¹⁸⁶ where I discuss the use of the classpath environment variable with a Java multimedia class library.

Some rules

There are some rules that you must follow when working with the classpath variable, and if you fail to do so, things simply won't work.

For example, if your class files are in a jar file, the classpath must end with the name of that jar file.

On the other hand, if the class files are not in a jar file, the classpath must end with the name of the folder that contains the class files.

Your classpath must contain a fully-qualified path name for every folder that contains class files of interest, or for every jar file of interest. The paths should begin with the letter specifying the drive and end either with the name of the jar file or the name of the folder that contains the class files. .

If you followed the default JDK installation procedure and are simply compiling and executing Java programs in the current directory you probably won't need to set the classpath. By default, the system already knows (*or can figure out*) how to allow you to compile and execute programs in the current directory and how to use the JDK classes that come as part of the JDK.

However, if you are using class libraries other than the standard Java library, are saving your class files in one or more different folders, or are ready to start creating your own packages, you will need to set the classpath so that the system can find the class files in your packages.

2.35.5 Developing your own packages

One of the problems with storing all of your class files in one or two folders is that you will likely experience name conflicts between class files.

Every Java program can consist of a large number of separate classes. A class file is created for each class that is defined in your program, even if they are all combined into a single source file.

It doesn't take very many programs to create a lot of class files, and it isn't long before you find yourself using the same class names over again. If you do, you will end up overwriting class files that were previously stored in the folder.

For me, it only takes two GUI programs to get in trouble because I tend to use the same class names in every program for certain standard operations such as closing a **Frame** or processing an **ActionEvent** . For the case of the **ActionEvent** , the body of the class varies from one application to the next so it doesn't make sense to turn it into a library class.

So we need a better way to organize our class files, and the Java package provides that better way.

The Java package approach allows us to store our class files in a hierarchy of folders (*or a jar file that represents that hierarchy*) while only requiring that the classpath variable point to the top of the hierarchy. The remaining hierarchy structure is encoded into our programs using package directives and import directives.

Now here is a little jewel of information that cost me about seven hours of effort to discover when I needed it badly.

When I first started developing my own packages, I spent about seven hours trying to determine why the compiler wouldn't recognize the top-level folder in my hierarchy of package folders.

I consulted numerous books by respected authors and none of them was any help at all. I finally found the following statement in the Java documentation (*when all else fails, read the documentation*) . By the way, a good portion of that wasted seven hours was spent trying to find this information in the documentation which is voluminous.

The following text was extracted directly from the JDK 1.1 documentation If you want the CLASSPATH to point to class files that belong to a package, you should specify a path

¹⁸⁵<http://docs.oracle.com/javase/7/docs/technotes/tools/windows/classpath.html>

¹⁸⁶<http://cnx.org/content/m44148>

name that includes the path to the directory one level above the directory having the name of your package.

For example, suppose you want the Java interpreter to be able to find classes in the package mypackage. If the path to the mypackage directory is C:\java\MyClasses\mypackage, you would set the CLASSPATH variable as follows:

```
set CLASSPATH=C:\java\MyClasses
```

If you didn't catch the significance of this, read it again. When you are creating a classpath variable to point to a folder containing classes, it must point to the folder. However, when you are creating a classpath variable to point to your package, it must point to the folder that is one level above the directory that is the top-level folder in your package.

Once I learned that I had to cause the classpath to point to the folder immediately above the first folder in the hierarchy that I was including in my package directives, everything started working.

2.35.5.1 The package directive

So, what is the purpose of a package directive, and what does it look like?

Purpose of a package directive The purpose of the package directive is to identify a particular class (*or group of classes contained in a single source file (compilation unit)*) as belonging to a specific package.

This is very important information for a variety of reasons, not the least of which is the fact that the entire access control system is wrapped around the concept of a class belonging to a specific package. For example, code in one package can only access public classes in a different package.

Stated in the simplest possible terms, a package is a group of class files contained in a single folder on your hard drive.

At compile time, a class can be identified as being part of a particular package by providing a package directive at the beginning of the source code.

A package directive, if it exists, must occur at the beginning of the source code (*ignoring comments and white space*) . No text other than comments and whitespace is allowed ahead of the package directive.

If your source code file does not contain a package directive, the classes in the source code file become part of the *default package* . With the exception of the default package, all packages have names, and those names are the same as the names of the folders that contain the packages. There is a one-to-one correspondence between folder names and package names. The default package doesn't have a name.

Some examples of package directives that you will see in upcoming sample programs follow:

Example package directives

```
package Combined.Java.p1;
package Combined.Java.p2;
```

Given the following as the classpath on my hypothetical machine,

```
CLASSPATH=.;c:\Baldwin\JavaProg
```

these two package directives indicate that the class files being governed by the package directives are contained in the following folders:

```
c:\Baldwin\JavaProg\Combined\Java\p1
c:\Baldwin\JavaProg\Combined\Java\p2
```

Notice how I concatenated the package directive to the classpath setting and substituted the backslash character for the period when converting from the package directive to the fully-qualified path name.

Code in one package can refer to a class in another package (*if it is otherwise accessible*) by qualifying the class name with its **package name as follows** :

```
Combined.Java.p2.Access02 obj02 =
    new Combined.Java.p2.Access02();
```

Obviously, if we had to do very much of that, it would become very burdensome due to the large amount of typing required. As you already know, the *import directive* is available to allow us to specify the package containing the class just once at the beginning of the source file and then refer only to the class name for the remainder of that source file.

2.35.5.2 The import directive

This discussion will be very brief because you have been using import directives since the very first module. Therefore, you already know what they look like and how to use them.

If you are interested in the nitty-gritty details (*such as what happens when you provide two import directives that point to two different packages containing the same class file name*) , you can consult the Java Language Reference by Mark Grand, or you can download the Java language specification from Oracle's Java website.

The purpose of the import directive is to help us avoid the burdensome typing requirement (p. 245) described in the previous section when referring to classes in a different package.

An import directive makes the definitions of classes from other packages available on the basis of their file names alone.

You can have any number of import directives in a source file. However, they must occur after the package directive (*if there is one*) and before any class or interface declarations.

There are essentially two different forms of the import directive, one with and the other without a wild card character (*) . These two forms are illustrated in the following box.

Two forms of import directives

```
import java.awt.*
import java.awt.event.ActionEvent
```

The first import directive makes all of the class files in the **java.awt** package available for use in the code in a different package by referring only to their file names.

The second import directive makes only the class file named **ActionEvent** in the **java.awt.event** package available by referring only to the file name.

2.35.5.3 Compiling programs with package directives

So, how do you compile programs containing package directives? There are probably several ways. I am going to describe one way that I have found to be successful.

First, you must create your folder hierarchy to match the package directive that you intend to use. Remember to construct this hierarchy downward relative to the folder specified at the end of your classpath setting. If you have forgotten the critical rule (p. 243) in this respect, go back and review it.

Next, place source code files in each of the folders where you intend for the class files associated with those source code files to reside. (*After you have compiled and tested the program, you can remove the source code files if you wish.*)

You can compile the source code files individually if you want to, but that isn't necessary.

One of the source code files will contain the *controlling class* . The controlling class is the class that contains the **main** method that will be executed when you run the program from the command line using the JVM.

Make the directory containing that source code file be the current directory. (*If you don't know what the current directory is, go out and get yourself a **DOS For Dummies** book and read it.*)

Each of the source code files must contain a package directive that specifies the package that will contain the compiled versions of all the class definitions in that source code file. Using the instructions that I am giving you, that package directive will also describe the folder that contains the source code file.

Any of the source code files containing code that refers to classes in a different package must also contain the appropriate import directives, or you must use fully-qualified package names to refer to those classes.

Then use the **javac** program with your favorite options to compile the source code file containing the controlling class. This will cause all of the other source code files containing classes that are linked to the code in the controlling class, either directly or indirectly, to be compiled also. At least an attempt will be made to compile them all. You may experience a few compiler errors if your first attempt at compilation is anything like mine.

Once you eliminate all of the compiler errors, you can test the application by using the **java** program with your favorite options to execute the controlling class.

Once you are satisfied that everything works properly, you can copy the source code files over to an archive folder and remove them from the package folders if you want to do so.

Finally, you can also convert the entire hierarchy of package folders to a jar file if you want to, and distribute it to your client. If you don't remember how to install it relative to the classpath variable, go back and review that part of the module.

Once you have reached this point, how do you execute the program. I will show you how to execute the program from the command line in the sample program in the next section. (*Actually I will encapsulate command-line commands in a batch file and execute the batch file. That is a good way to guard against typing errors.*)

2.35.5.4 Sample program

The concept of packages can get very tedious in a hurry. Let's take a look at a sample program that is designed to pull all of this together.

This application consists of three separate source files located in three different packages. Together they illustrates the use of package and import directives, along with **javac** to build a standalone Java application consisting of classes in three separate packages.

(*If you want to confirm that they are really in different packages, just make one of the classes referred to by the controlling class non-public and try to compile the program.*)

In other words, in this sample program, we create our own package structure and populate it with a set of cooperating class files.

A folder named **jnk** is a child of the root folder on the M-drive.

A folder named **SampleCode** is a child of the folder named **jnk** .

A folder named **Combined** is a child of the folder named **SampleCode** .

A folder named **Java** is a child of the folder named **Combined** .

Folders named **p1** and **p2** are children of the folder named **Java** .

The file named **Package00.java** , shown in Listing 1 (p. 247) is stored in the folder named **Java** .

Code in the **main** method of the controlling class in Listing 1 (p. 247) instantiates objects of the other two classes in different packages. The constructors for those two classes announce that they are being constructed.

The two classes being instantiated are **public** . Otherwise, it would not be possible to instantiate them from outside their respective packages.

This program was tested using JDK 7 under Windows by executing the batch file named **CompileAndRun.bat** .

The classpath is set to the parent folder of the folder named **Combined** (*M:\jnk\SampleCode*) by the **-cp** switch in the file named **CompileAndRun.bat** .

The output from running the program is shown in the comments at the beginning of Listing 1 (p. 247) .

2.35.6 Run the program

I encourage you to copy the code from Listing1 (p. 247) through Listing 4 (p. 249) into a properly constructed tree of folders. Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

2.36.2 Preface

This module discusses the `String` and `StringBuffer` classes in detail.

2.36.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the listings while you are reading about them.

2.36.2.1.1 Listings

- Listing 1 (p. 252) . File `String01.java`
- Listing 2 (p. 254) . File `String02.java`.

2.36.3 Introduction

A string in Java is an object. Java provides two different string classes from which objects that encapsulate string data can be instantiated:

- `String`
- `StringBuffer`

The `String` class is used for strings that are not allowed to change once an object has been instantiated (*an immutable object*) . The `StringBuffer` class is used for strings that may be modified by the program.

2.36.4 You can't modify a `String` object, but you can replace it

While the contents of a `String` object cannot be modified, a reference to a `String` object can be caused to point to a different `String` object as illustrated in the sample program shown in Listing 1 (p. 252) . Sometimes this makes it appear that the original `String` object is being modified.

Listing 1 . File String01.java.

```

/*File String01.java Copyright 1997, R.G.Baldwin
This application illustrates the fact that while a String
object cannot be modified, the reference variable can be
modified to point to a new String object which can have
the appearance of modifying the original String object.

The program was tested using JDK 1.1.3 under Win95.

The output from this program is

Display original string values
THIS STRING IS NAMED str1
This string is named str2
Replace str1 with another string
Display new string named str1
THIS STRING IS NAMED str1 This string is named str2
Terminating program

*****/

class String01{
    String str1 = "THIS STRING IS NAMED str1";
    String str2 = "This string is named str2";

    public static void main(String[] args){
        String01 thisObj = new String01();
        System.out.println("Display original string values");
        System.out.println(thisObj.str1);
        System.out.println(thisObj.str2);
        System.out.println("Replace str1 with another string");
        thisObj.str1 = thisObj.str1 + " " + thisObj.str2;
        System.out.println("Display new string named str1");
        System.out.println(thisObj.str1);
        System.out.println("Terminating program");
    }//end main()
} //end class String01

```

Table 2.102

It is important to note that the following statement does not modify the original object pointed to by the reference variable named **str1** .

```
thisObj.str1 = thisObj.str1 + " " + thisObj.str2;
```

Rather, this statement creates a new object, which is concatenation of two existing objects and causes the reference variable named `str1` to point to the new object instead of the original object.

The original object then becomes eligible for garbage collection (*unless there is another reference to the object hanging around somewhere*).

Many aspects of string manipulation can be accomplished in this manner, particularly when the methods of the `String` class are brought into play.

2.36.5 Why are there two string classes?

According to *The Java Tutorial* by Campione and Walrath:

"Because they are constants, Strings are typically cheaper than StringBufferes and they can be shared. So it's important to use Strings when they're appropriate."

2.36.6 Creating String and StringBuffer objects

The `String` and `StringBuffer` classes have numerous overloaded constructors and many different methods. I will attempt to provide a sampling of constructors and methods that will prepare you to explore other constructors and methods on your own.

The next sample program touches on some of the possibilities provided by the wealth of constructors and methods in the `String` and `StringBuffer` classes.

At this point, I will refer you to Java OOP: Java Documentation ¹⁹² where you will find a link to online Java documentation. Among other things, the online documentation provides a list of the overloaded constructors and methods for the `String` and `StringBuffer` classes.

As of Java version 7, there are four overloaded constructors in the `StringBuffer` class and about thirteen different overloaded versions of the `append` method. There are many additional methods in the `StringBuffer` class including about twelve overloaded versions of the `insert` method.

As you can see, there are lots of constructors and lots of methods from which to choose. One of your challenges as a Java programmer will be to find the right methods of the right classes to accomplish what you want your program to accomplish.

2.36.6.1 The sample program named String02

The sample program shown in Listing 2 (p. 254) illustrates a variety of ways to create and initialize `String` and `StringBuffer` objects.

¹⁹²<http://cnx.org/content/m45117>

Listing 2 . File String02.java.

```

StringBuffer objects.

The program was tested using JDK 1.1.3 under Win95.

The output from this program is as follows. In some cases,
manual line breaks were inserted to make the material fit
this presentation format.

Create a String the long way and display it
String named str2

Create a String the short way and display it
String named str1

Create, initialize, and display a StringBuffer using new
StringBuffer named str3

Try to create/initialize StringBuffer without
using new - not allowed

Create an empty StringBuffer of default length
Now put some data in it and display it
StringBuffer named str5

Create an empty StringBuffer and specify length
when it is created
Now put some data in it and display it
StringBuffer named str6

Try to create and append to StringBuffer without
using new -- not allowed

class String02{
    void d(String displayString){//method to display strings
        System.out.println(displayString);
    }//end method d()

    public static void main(String[] args){
        String02 o = new String02();//obj of controlling class

        o.d("Create a String the long way and display it");
        String str1 = new String("String named str2");
        o.d(str1 + "\n");

        o.d("Create a String the short way and display it");
        String str2 = "String named str1";
        o.d(str2 + "\n");

        o.d("Create, initialize, and display a StringBuffer " +
            "using new");

```

Table 2.103

2.36.6.2 Alternative String instantiation constructs

The first thing to notice is that a **String** object can be created using either of the following constructs:

Alternative String instantiation constructs

```
String str1 = new String("String named str2");

String str2 = "String named str1";
```

The first approach uses the **new** operator to instantiate an object while the shorter version doesn't use the new operator.

Later I will discuss the fact that

- the second approach is not simply a shorthand version of the first construct, but that
- they involve two different compilation scenarios with the second construct being more efficient than the first.

2.36.6.3 Instantiating StringBuffer objects

The next thing to notice is that a similar alternative strategy does not hold for the **StringBuffer** class.

For example, it is not possible to create a **StringBuffer** object without use of the **new** operator. *(It is possible to create a reference to a **StringBuffer** object but it is later necessary to use the **new** operator to actually instantiate an object.)*

Note the following code fragments that illustrate allowable and non-allowable instantiation scenarios for **StringBuffer** objects.

Instantiating StringBuffer objects

```
//allowed
StringBuffer str3 = new StringBuffer(
    "StringBuffer named str3");

//not allowed
//StringBuffer str4 = "StringBuffer named str4";

o.d("Try to create and append to StringBuffer " +
    "without using new -- not allowed");
//StringBuffer str7;
//str7.append("StringBuffer named str7");
```

2.36.6.4 Declaration, memory allocation, and initialization

To review what you learned in an earlier module, three steps are normally involved in creating an object (*but the third step may be omitted*) .

- declaration
- memory allocation
- initialization

The following code fragment performs all three steps:

Declaration, memory allocation, and initialization

```
StringBuffer str3 =
    new StringBuffer("StringBuffer named str3");
```

The code

```
StringBuffer str3
```

declares the type and name of a reference variable of the correct type for the benefit of the compiler.

The **new** operator allocates memory for the new object.

The constructor call

```
StringBuffer("StringBuffer named str3")
```

constructs and initializes the object.

2.36.6.5 Instantiating an empty StringBuffer object

The instantiation of the **StringBuffer** object shown above (p. 256) uses a version of the constructor that accepts a **String** object and initializes the **StringBuffer** object when it is created.

The following code fragment instantiates an empty **StringBuffer** object of a default capacity and then uses a version of the **append** method to put some data into the object. (*Note that the data is actually a **String** object – a sequence of characters surrounded by quotation marks.*)

Instantiating an empty StringBuffer object

```
//default initial length
StringBuffer str5 = new StringBuffer();

//modify length as needed
str5.append("StringBuffer named str5");
```

It is also possible to specify the capacity when you instantiate a **StringBuffer** object.

Some authors suggest that if you know the final length of such an object, it is more efficient to specify that length when the object is instantiated than to start with the default length and then require the system to increase the length "on the fly" as you manipulate the object.

This is illustrated in the following code fragment. This fragment also illustrates the use of the **length** method of the **String** class just to make things interesting. (*A simple integer value for the capacity of the **StringBuffer** object would have worked just as well.*)

Instantiating a StringBuffer object of a non-default length

```
StringBuffer str6 = new StringBuffer(
    "StringBuffer named str6".length());
str6.append("StringBuffer named str6");
```

2.36.7 Accessor methods

The following quotation is taken directly from *The Java Tutorial* by Campione and Walrath.

"An object's instance variables are encapsulated within the object, hidden inside, safe from inspection or manipulation by other objects. With certain well-defined exceptions, the object's methods are the only means by which other objects can inspect or alter an object's instance variables. Encapsulation of an object's data protects the object from corruption by other objects and conceals an object's implementation details from outsiders. This encapsulation of data behind an object's methods is one of the cornerstones of object-oriented programming."

The above statement lays out an important consideration in good object-oriented programming.

The methods used to obtain information about an object are often referred to as *accessor methods* .

2.36.7.1 Constructors and methods of the `String` class

I told you in an earlier section (p. 253) that the `StringBuffer` class provides a large number of overloaded constructors and methods. The same holds true for the `String` class.

Once again, I will refer you to Java OOP: Java Documentation ¹⁹³ where you will find a link to online Java documentation. Among other things, the documentation provides a list of the overloaded constructors and methods for the `String` class

2.36.7.2 `String` objects encapsulate data

The characters in a `String` object are not directly available to other objects. However, as you can see from the documentation, there are a large number of methods that can be used to access and manipulate those characters. For example, in an earlier sample program (*Listing 2 (p. 254)* (p. 254)), I used the `length` method to access the number of characters stored in a `String` object as shown in the following code fragment.

```
StringBuffer str6 = new StringBuffer(
    "StringBuffer named str6".length());
```

In this case, I applied the `length` method to a literal string, but it can be applied to any valid representation of an object of type `String` .

I then passed the value returned by the `length` method to the constructor for a `StringBuffer` object. As you can determine by examining the argument lists for the various methods of the `String` class,

- some methods return data stored in the string while
- other methods return information about that data.

For example, the `length` method returns information about the data stored in the `String` object.

Methods such as `charAt` and `substring` return portions of the actual data.

Methods such `toUpperCase` can be thought of as returning the data, but returning it in a different format.

¹⁹³<http://cnx.org/content/m45117>

2.36.7.3 Creating String objects without calling the constructor

Methods in other classes and objects may create **String** objects without an explicit call to the constructor by the programmer. For example the **toString** method of the **Float** class receives a **float** value as an incoming parameter and returns a reference to a **String** object that represents the **float** argument.

2.36.8 Memory management by the StringBuffer class

If the additional characters cause the size of the **StringBuffer** to grow beyond its current capacity when characters are added, additional memory is automatically allocated.

However, memory allocation is a relatively expensive operation and you can make your code more efficient by initializing **StringBuffer** capacity to a reasonable first guess. This will minimize the number of times memory must be allocated for it.

When using the **insert** methods of the **StringBuffer** class, you specify the index *before which* you want the data inserted.

2.36.9 The toString method

Frequently you will need to convert an object to a **String** object because you need to pass it to a method that accepts only **String** values (*or perhaps for some other reason*) .

All classes inherit the **toString** method from the **Object** class. Many of the classes *override* this method to provide an implementation that is meaningful for objects of that class.

In addition, you may sometimes need to *override* the **toString** method for classes that you define to provide a meaningful **toString** behavior for objects of that class.

I explain the concept of overriding the **toString** method in detail in the module titled Java OOP: Polymorphism and the Object Class ¹⁹⁴ .

2.36.10 Strings and the Java compiler

In Java, you specify literal strings between double quotes as in:

Literal strings

```
"I am a literal string of the String type."
```

You can use literal strings anywhere you would use a **String** object.

You can also apply **String** methods directly to a literal string as in an earlier program (p. 254) that calls the **length** method on a literal string as shown below.

Using String methods with literal strings

```
StringBuffer str6 = new StringBuffer(  
    StringBuffer named str6".length());
```

Because the compiler automatically creates a new **String** object for every literal string, you can use a literal string to initialize a **String** object (*without use of the new operator*) as in the following code fragment from a previous program (p. 252) :

¹⁹⁴<http://cnx.org/content/m44190>

```
String str1 = "THIS STRING IS NAMED str1";
```

The above construct is equivalent to, but more efficient than the following, which, according to *The Java Tutorial* by Campione and Walrath, ends up creating two **String** objects instead of one:

```
String str1 = new String("THIS STRING IS NAMED str1");
```

In this case, the compiler creates the first **String** object when it encounters the literal string, and the second one when it encounters `new String()`.

2.36.11 Concatenation and the + operator

The plus (+) operator is overloaded so that in addition to performing the normal arithmetic operations, it can also be used to concatenate strings.

This will come as no surprise to you because we have been using code such as the following since the beginning of this group of *Programming Fundamentals* modules:

```
String cat = "cat";
```

```
System.out.println("con" + cat + "enation");
```

According to Campione and Walrath, Java uses **StringBuffer** objects behind the scenes to implement concatenation. They indicate that the above code fragment compiles to:

```
String cat = "cat";
System.out.println(new StringBuffer().append("con").
    append(cat).append("enation"));
```

Fortunately, that takes place behind the scenes and we don't have to deal directly with the syntax.

2.36.12 Run the programs

I encourage you to copy the code from Listing 1 (p. 252) and Listing 2 (p. 254). Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

2.36.13 Looking ahead

As you approach the end of this group of *Programming Fundamentals* modules, you should be preparing yourself for the more challenging ITSE 2321 OOP¹⁹⁵ tracks identified below:

3.1.1.2 Welcome

Welcome to the course material for **ITSE 2321 - Object-Oriented Programming (Java)**, which I teach at Austin Community College ⁴ in Austin, TX.

The college website for this course is: <http://www.austincc.edu/baldwin/> ⁵

3.1.1.3 Course description

As of November 2012, the description for this course reads:

"ITSE 2321 - Object-Oriented Programming (Java)

Introduction to object-oriented programming. Emphasis on the fundamentals of structured design with classes, including development, testing, implementation, and documentation. Includes object-oriented programming techniques, classes, and objects."

3.1.1.4 Course prerequisite

The prerequisite for the course is COSC 1336 or department approval.

As of November 2012, the description for the prerequisite course reads:

"COSC 1336 - Programming Fundamentals I

Introduces the fundamental concepts of structured programming. Topics include software development methodology, data types, control structures, functions, arrays, and the mechanics of running, testing, and debugging. This course assumes computer literacy. This course requires the same math skills necessary for College Algebra. Students should either have taken or be currently enrolled in College Algebra or a course that requires College Algebra."

3.1.1.4.1 Prerequisite waiver

Beginning in August of 2013, you might want to petition the department head for a waiver of the prerequisite course if you meet the following requirements:

- You understand and can answer at least 80-percent of the questions in modules Ap0005: Preface to OOP Self-Assessment ⁶ through Ap0060: Self-assessment, More on Arrays ⁷ in a "closed-book" setting.
- You understand and can write at least 80-percent of the programs in the *Challenge program questions* in modules Ap0005: Preface to OOP Self-Assessment ⁸ through Ap0060: Self-assessment, More on Arrays ⁹ in a "closed-book" setting.
- You understand and can answer at least 80-percent of the questions posed on the *Review* pages in *Programming Fundamentals* ¹⁰ in a "closed-book" setting

3.1.1.5 Prior to enrolling

I recommend that you understand and be able to answer at least 80-percent of the questions in modules Ap0005: Preface to OOP Self-Assessment ¹¹ through Ap0060: Self-assessment, More on Arrays ¹² in a "closed-book" setting.

3.1.1.6 Course material

This course material consists of a more than 30 different modules arranged in the following sections:

- Preface
 - Preface to ITSE 2321
 - Completing the First Assignment
 - Configuring Your Computer
- Essence of OOP
- Multimedia
- The Java Collections Framework
- Practice Programs
- Java Documentation

3.1.1.6.1 Preface

3.1.1.6.1.1 Preface to ITSE 2321

This is the module ¹⁶ that you are reading now.

3.1.1.6.1.2 Completing the First Assignment

This module ¹⁷ helps students navigate through the learning process so that they can complete the first assignment on or before the deadline.

3.1.1.6.1.3 Configuring Your Computer

This module ¹⁸ provides a step-by-step procedure for configuring a Windows computer to support the types of sample programs and assignments involved in this course.

Perhaps the first thing that you should do when considering enrollment in this course is to visit this module ¹⁹ and confirm that you are able to understand and to replicate the procedures and the results explained there.

3.1.1.6.2 Essence of OOP

The modules in the Essence of OOP ²⁰ section are more or less theoretical in nature. Sample programs in this section are intended to illustrate the OOP concepts being discussed with no effort being made to cause those programs to have any relation to real-world applications.

3.1.1.6.3 Multimedia

The modules in the Multimedia ²¹ section are intended to illustrate OOP concepts using sample programs that clearly represent real-world applications. In particular, most of the sample programs in this section use OOP concepts to manipulate digital images of the sort that are produced by your digital camera. (See *some examples in Java3000: The Guzdial-Ericson Multimedia Class Library* ²² .)

3.1.1.6.4 The Java Collections Framework

The modules in this section are intended to help you learn about The Java Collections Framework ²³ . Once you learn how to use the framework, it is unlikely that you will need to reinvent common data structures, search algorithms, or sorting algorithms again, because those capabilities are neatly packaged within the framework.

3.1.1.6.5 Practice Programs

This section ²⁴ provides the source code for a large number of programs illustrating important aspects of object-oriented programming with Java.

3.1.1.6.6 Java Documentation

As the name suggests, the material in this section is intended to show you how to access and how to use the standard Java documentation.

3.1.1.7 Downloads

Unless the format has changed, you should be able to see a green button labeled **Get This Book!** near the upper-right on this page. (You may need to adjust the zoom factor on your browser to cause it to appear. If you don't see the green button, scroll to the bottom of this page where you should see a tab labeled **Downloads+** .) Click the button or the tab to see some of the download options for this book.

You may find additional download options both for the book (*collection*) and for the individual page (*module*) by:

- Clicking the link labeled **CNX Author | Legacy Site** in the upper right corner of this or any other page in the book.
- Scrolling to the bottom of the page on the legacy site where you may see a **DOWNLOAD:** label, below which you may see a **COLLECTION AS:** label and a **MODULE AS:** label.
- Selecting the link labeled **More downloads...** to the right of either of those labels.

I encourage you to take advantage of all of the download options that OpenStax has to offer in order to customize this material for use in your organized courses or for personal self study. If you elect to download the book in the **Offline ZIP** format, see the book titled OpenStax Download Cleaner ²⁵ for instructions on how to make that material more useful than it might otherwise be.

And if you find the material useful, I would like to hear more about how you are using it.

3.1.2.2 Preface

Many students in this course have difficulty getting started and fail to submit the first assignment by the prescribed deadline. Many (*but not all*) of those students either withdraw too late to get a refund or fail the course altogether.

The purpose of this lesson is to lay out a set of steps that students can follow in order

- to get started promptly, and
- to submit a correct copy of the first assignment before the deadline.

Note that this lesson won't write the first assignment for you. Rather, it will help you navigate the learning process so that you can accomplish that on your own.

3.1.2.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

3.1.2.2.1.1 Figures

- Figure 1. (p. 281) Graphic output from Turtles01.
- Figure 2. (p. 282) Graphic output from Circles01.

3.1.2.2.1.2 Listings

- Listing 1 (p. 282) . The driver class named Turtles01.
- Listing 2 (p. 283) . The class named Turtles01Runner.
- Listing 3 (p. 284) . The class named Circles01.
- Listing 4 (p. 284) . The class named Circles01Runner.

3.1.2.3 General background information

This section will describe the things that you need to do before you begin writing code for the first assignment.

3.1.2.3.1 Orientation and the rules of the road

As of September 2016, Austin Community College²⁹ uses a learning management system (*LMS*) known as Blackboard (*Bb*)³⁰. When you enroll in this course, you will have access to the course in Bb. The first thing that you should do is to open the course in Bb and read all of the announcements, paying particular attention to the requirement for online orientation.

The next thing that you should do is go to the page³¹ on the college website containing links to all of the courses that I teach. Locate your course among the various courses listed there. Select the link that points to the syllabus page for my courses. Then select the link to the syllabus for your course and read the syllabus. Make certain that you understand all of the information provided in the syllabus.

Once you understand the information in the syllabus, return to the page³² containing links to all of the courses that I teach. Locate your course among the various courses listed there and select the link that points to the **Main page** for your course. Read that page and all of the pages referenced by links on that page.

²⁹<http://www.austincc.edu/>

³⁰<http://www.blackboard.com/learning-management-system/blackboard-learn.aspx>

³¹<http://www.austincc.edu/baldwin/>

³²<http://www.austincc.edu/baldwin/>

By this point, you should fully understand the rules of the road for this course. Go back to your course in Bb and complete the orientation test.

If you have questions along the way, be sure to ask those questions.

3.1.2.3.2 Configure your computer

The next step is to configure your computer to make it compatible with the requirements of this course. Go to Java 1560: Configuring Your Computer ³³ . Study that lesson carefully. Make absolutely certain that you can replicate all of the procedures and results shown there with the possible exception of the material in the section titled Compare the graphic output from each of two Java programs ³⁴ . (*I exclude that section only because you don't have the output from two Java programs to compare at this point.*)

Once you have accomplished that, you should probably skip ahead and confirm that you can replicate the procedures and results described in the lesson titled Java3000: The Guzdial-Ericson Multimedia Class Library ³⁵ . You could hold off and do that later if you prefer but you definitely need to accomplish that before you begin to write your first assignment program.

3.1.2.3.3 Review programming fundamentals in Java

Now that you have your computer configured, it is time to begin learning how to use the Java programming language for object-oriented programming. The first step is to review the Ebook titled Programming Fundamentals with Java ³⁶ in whatever depth you need in order to transfer your prior knowledge of programming fundamentals to the Java programming language. (*Note that the previous text refers to **programming fundamentals** and not to **object-oriented programming fundamentals** . That is the topic of the next section.*)

3.1.2.3.4 Learn object-oriented programming fundamentals

This is where things become more interesting. At this point, you will need to begin studying three portions of two different Ebooks in parallel and to integrate what you learn in your mind.

First and foremost, you need to begin studying the material that begins at Java1600: Objects and Encapsulation ³⁷ in order to start understanding the important aspects of object-oriented programming.

In conjunction with that, you need to start taking the assessment tests in the Ebook titled Java OOP Self-Assessment ³⁸ to confirm your knowledge of that material.

Once you start feeling comfortable that you are gaining an understanding of OOP from a largely theoretical viewpoint, you need to study the following six lessons for the purpose of applying the OOP concepts to **more meaningful programs** .

- Java3000: The Guzdial-Ericson Multimedia Class Library ³⁹
- Java3000r Review ⁴⁰
- Java3002: Creating and Manipulating Turtles and Pictures in a World Object ⁴¹
- Java3002r Review ⁴²
- Java3003: Drawing Graphs with Turtles and Pixels ⁴³

3.1.2.4 Discussion and sample code

By the time you understand the material in the six lessons listed above (p. 279) , you should be fully capable of writing and submitting a correct version of the first assignment. However, in case you need more help in that regard, I am going to provide two sample programs, each of which deals with part of the requirements of the first programming assignment. It will be up to you to understand and to integrate the concepts illustrated by these sample programs into a single program that satisfies the requirements of the first assignment.

Note that in addition to these two sample programs and the sample programs in the lessons listed above (p. 279) , there are many other sample programs in the section of the Ebook that begins here ⁴⁶ .

3.1.2.4.1 Working with turtles in general

Most of the programming assignments in this course are structured as follows. Along with a program specification document, I provide a short Java source code file containing a class definition that I often refer to as the driver class. I also provide any necessary image files.

The student is not allowed to make any changes to the driver class. Instead, the student must write one or more source code files which, when compiled and executed in conjunction with the driver class, will produce the required output. In the program that I describe here, the driver class is named **Turtles01** and the code that the student would be required to write would be in the class named **Turtles01Runner** .

The student only submits the source code files for the classes defined by the student. In this program, that code would be in a file named **Turtles01Runner.java** .

Listing 1 (p. 282) and Listing 2 (p. 283) near the end of the lesson show the source code for the driver class and the **Turtles01Runner** class for this program.

This program produces the output image shown in Figure 1 (p. 281) .

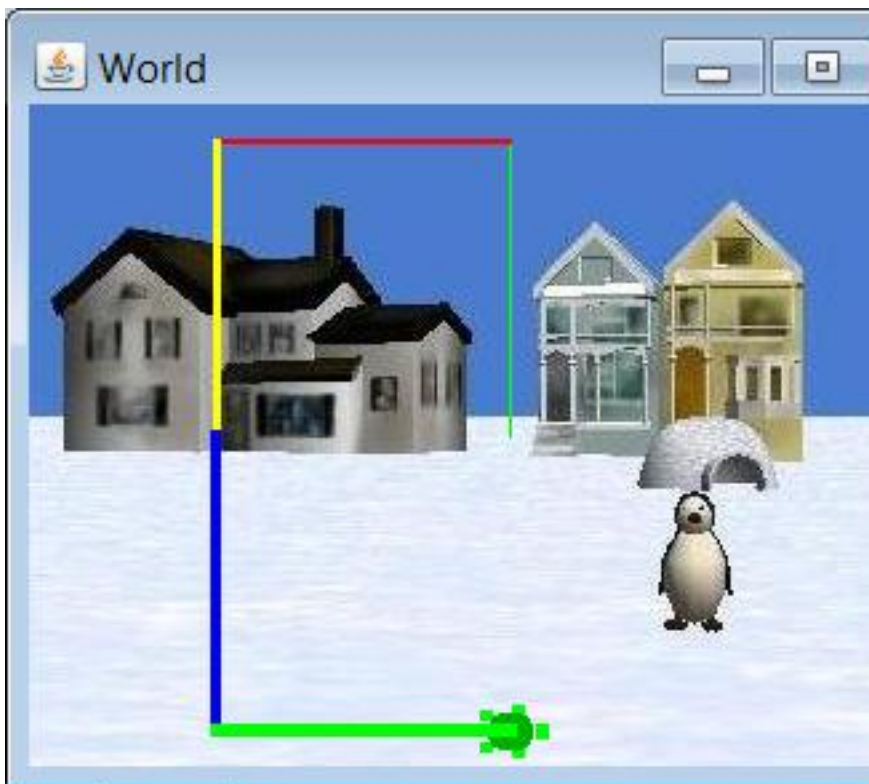

Figure 1. Graphic output from Turtles01.

Once you have access to the first assignment, you should be able to see some similarities between the output image in Figure 1 (p. 281) and the required output image for the first assignment.

3.1.2.4.2 Drawing a circle with a turtle

Like the previous program, the program presented in this section has a driver class named **Circles01** and another class named **Circles01Runner**. The source code for those two class definitions is shown in Listing 3 (p. 284) and Listing 4 (p. 284).

The output image produced by this program is shown in Figure 2 (p. 282).

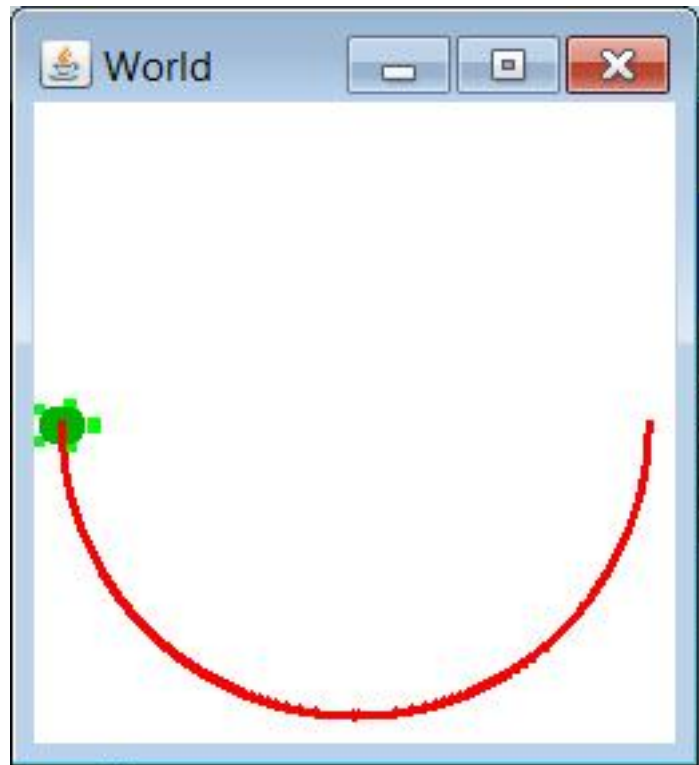

Figure 2. Graphic output from Circles01.

3.1.2.5 Run the programs

I encourage you to copy the code from Listing 1 (p. 282) through Listing 4 (p. 284) . Compile and execute the code for each program and confirm that you get the same results as those shown in Figure 1 (p. 281) and Figure 2 (p. 282) . (Click here ⁴⁷ to download a zip file containing the image file required by the Turtles program.)

Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

Various lessons in those Ebooks explain how to configure your computer for compiling and executing the sample programs in those Ebooks. However, I continue to receive questions from students in this course (*ITSE 2321 - Object-Oriented Programming (Java)*) who are confused about how to configure their computers for this course.

In this lesson, I will provide a step-by-step procedure for configuring a Windows computer to support the types of sample programs and assignments involved in this course. This won't be the most elegant procedure or necessarily the best procedure. However, it will be a procedure that should make it possible for students having minimal knowledge of such topics as Windows *environment variables* , Windows *batch files* , Windows *command-line operations* , etc. to successfully configure their computer for use in this course.

Note: If you are using an operating system other than Windows, you may need to find someone who can translate the steps in this procedure into the corresponding set of steps for your operating system.

The instructions in this procedure will be current for the 64-bit version of Windows 7 and the Java JDK in September of 2016. As time goes by, some of the links may change and you may need to modify your response to the instructions to accommodate those changes. Also, the user interface for newer versions of Windows may be different from Windows 7. An effort will be made to write the instructions in such a way as to accommodate such changes.

You will probably need administrator privileges on your computer in order to install the software.

The instructions in this procedure will concentrate on the "*what*" and not the "*why*" .. Don't be concerned if you don't understand the code used in these instructions. You will learn *why* the code behaves as it does in future lessons. Just follow the instructions and confirm that you can produce the results shown in this lesson to confirm that your computer is properly configured.

3.1.3.3 Download, install, and test the Java Development Kit (JDK)

The first step is to download, install, and test the Java Development Kit (JDK) from the Oracle website.

3.1.3.3.1 Download and install the JDK

Open the Oracle website in your browser at <http://www.oracle.com/technetwork/java/javase/downloads/index.html>⁷¹.

Click the download button labeled **Java Platform (JDK) 8u101 / 8u102** . (Note that this label and the labels and titles mentioned below may change as newer versions of the JDK are released.)

Click the radio button labeled **Accept License Agreement** in the section titled **Java SE Development Kit 8u101** .

Locate the line item labeled **Windows x64** in the column titled **Product/File Description** .

Click the link labeled **jdk-8u101-windows-x64.exe** in the column labeled **Download** immediately to the right of the **Windows x64** label.

Click the **Save File** button when the Windows dialog opens asking if you would like to save this file. Depending on the version of the JDK, a file with a name similar to **jdk-8u101-windows-x64.exe** will be saved in the folder that your computer and your browser uses to save download files. Find and double-click that file. Click the **Yes** button when Windows asks if you want to allow the program to make changes to your computer.

A series of installation dialogs will be presented by Windows. Simply click the **Next** button in each dialog to cause the full JDK to be installed in the default location on your C-drive. Click the **Close** button in the final dialog that appears indicating that the JDK has been successfully installed.

Open Windows Explorer on the C-drive and navigate to a folder having a path similar to **C:\Program Files\Java\jdk1.8.0_101\bin** . (The exact name will depend on the version of the JDK that you downloaded.) Write the path down somewhere and save it because you are going to need it later.

Examine the contents of the **bin** folder. It should contain a large number of files including the following two files: **javac.exe** and **java.exe** . Those are the program files for the compiler and the Java Virtual Machine respectively. As you will see later, they are used to compile and run a Java program.

At this point, if you are skilled at such Windows operations as setting environment variables, you can return to the page at <http://www.oracle.com/technetwork/java/javase/downloads/index.html>⁷², find and select a link to **Installation instructions**, and complete the installation according to those instructions. However, many students in this course don't have those skills. If you are in group that lacks those skills, you can simply skip this step and continue with the following section titled Test the JDK. The following instructions assume that you have skipped this step.

3.1.3.3.2 Test the JDK

Now that you have installed the JDK, you need to test it to confirm that it is properly installed.

Open Windows Explorer and create an empty folder somewhere on your C-drive; it doesn't matter where you locate the folder. Name the folder **JDKtest** .

Using Windows Notepad along with the path that you saved earlier, create a file named **JDKtest.bat** in that folder containing the text shown in Listing 1 (p. 289) . Use your path in place of my path to construct

⁷¹<http://www.oracle.com/technetwork/java/javase/downloads/index.html>

⁷²<http://www.oracle.com/technetwork/java/javase/downloads/index.html>

the command. (Note that the extension must be *.bat* and not *.txt*. Note also that you must surround the path that you saved earlier with matching quotation characters when you construct the command.)

Listing 1 . Initial contents of JDKtest.bat.

```
echo off
"C:\Program Files\Java\jdk1.8.0_101\bin"\javac -version
pause
```

Double click the file named **JDKtest.bat** . If everything has been done correctly up to this point, a black command-line window should appear on your screen containing text similar to that shown in Figure 1 (p. 289) .

Figure 1. Screen output for the initial test.

```
C:\jnk\6\JDKtest>echo off
javac 1.8.0_101
Press any key to continue . . .
```

The first line of text in your output will reflect the location of the folder named **JDKtest** on your C-drive. The second line of text will reflect the version number of the JDK that you have installed.

The third line of text should be unchanged unless a future version of Windows changes the format of that line of text. (This line of text is produced by the **pause** command in the batch file. Without this command, the command-line window would appear momentarily and then disappear before you have a chance to examine it.)

If you are unable to get this result, you need to go back and follow the steps more carefully. If you are certain that you have followed the steps and are still unable to get this result, please let me know. It is possible that I may have made an error in describing the steps or that I need to update the steps to accommodate a future version of the JDK or of Windows.

If you do get this result, update the contents of the file named **JDKtest.bat** to match that shown in Listing 2 (p. 289) .

Listing 2 . Expanded contents of JDKtest.bat.

```
echo off
"C:\Program Files\Java\jdk1.8.0_101\bin"\javac -version
"C:\Program Files\Java\jdk1.8.0_101\bin"\java -version
pause
```

Double click the file named **JDKtest.bat** . A black command-line window should appear on your screen containing text similar to that shown in Figure 2 (p. 289) .

Figure 2. Screen output for the expanded test.

```
C:\jnk\6\JDKtest>echo off
javac 1.8.0_101
java version "1.8.0_101"
Java(TM) SE Runtime Environment (build 1.8.0_101-b13)
Java HotSpot(TM) 64-Bit Server VM (build 25.101-b13, mixed mode)
Press any key to continue . . .
```

The second and third lines of text should reflect the version of the JDK that you have installed.

The fourth and fifth lines of text will be different for future versions of the JDK but they should be similar to that shown.

Once again, if you are unable to get this result, you need to go back and follow the steps more carefully.

If you are able to get this result, this confirms that the JDK is properly installed on your computer.

3.1.3.3.3 Compile and run a simple text-based Java program with a single source code file

Now that you have confirmed that the JDK is properly installed on your computer, it is time to write, compile, and execute a very simple Java program.

Using Windows Explorer, open a new folder on your C-drive named **Hello01** . Using Notepad or another text editor of your choice, create a file in that folder named **Hello01.java** containing the code shown in Listing 3 (p. 290) .

Listing 3 . Source code for the class named Hello01.

```
class Hello01{
    public static void main(String[] args){
        System.out.println("Hello World from Hello01");
    }//end main
} //end class
```

Now using the path that you saved earlier, create a batch file named **Hello01.bat** in that same folder containing the commands shown in Listing 4 (p. 290) .

Listing 4 . Commands for the batch file named Hello01.bat.

```
echo off
"C:\Program Files\Java\jdk1.8.0_101\bin"\javac Hello01.java
"C:\Program Files\Java\jdk1.8.0_101\bin"\java Hello01
pause
```

Double click the batch file. A black command-line screen should appear and display the program output text shown in Figure 3 (p. 290) .

Figure 3. Text output from the program named Hello01.

```
Hello World from Hello01
Press any key to continue . . .
```

3.1.3.3.4 Compile and run a simple text-based Java program with two source code files

Assuming that you were able to produce the output shown in the previous section it's time to write, compile, and execute a slightly more complex program consisting of two Java source code files.

Create a new folder named **Hello02** . Create a Java source code file in that folder named **Hello02.java** containing the code shown in Listing 5 (p. 290) .

Listing 5 . Source code for the class named Hello02.

```
class Hello02{
    public static void main(String[] args){
        new Hello02Runner().run();
    }//end main
} //end class
```

Create another Java source code file in that folder named **Hello02Runner.java** containing the code shown in Listing 6 (p. 291) .

Listing 6 . Source code for the class named Hello02Runner.

```
class Hello02Runner{
    void run(){
        System.out.println("Hello World from Hello02");
    } //end main
} //end class
```

Create a batch file named **Hello02.bat** containing the commands shown in Listing 7 (p. 291) .

Listing 7 . Commands for the batch file named Hello02.bat.

```
echo off
"C:\Program Files\Java\jdk1.8.0_101\bin"\javac Hello02.java
"C:\Program Files\Java\jdk1.8.0_101\bin"\java Hello02
pause
```

Double click the batch file. A black command-line screen should appear and display the program output text shown in Figure 4 (p. 291) .

Figure 4. Text output from the program named Hello02.

```
Hello World from Hello02
Press any key to continue . . .
```

If you have been successful to this point, you should now be able to compile and execute the code for any text-based program involved in this course.

3.1.3.4 Download, install, and test the multimedia library

Many of the sample programs and assignments in this course make use of a multimedia class library developed and made available by Mark Guzdial ⁷³ and Barbara Ericson ⁷⁴ of the Georgia Institute of Technology. Therefore, it will be necessary for you to download and install that library on your computer.

The Guzdial-Ericson library was originally published by Guzdial and Ericson in conjunction with their book *Introduction to Computing and Programming with Java: A Multimedia Approach* ⁷⁵ . While the book isn't free, the library is freely available and is published under a Creative Commons Attribution 3.0 United States License ⁷⁶ .

⁷³<http://www.cc.gatech.edu/~guzdial/>

⁷⁴<http://coweb.cc.gatech.edu/ice-gt/8>

⁷⁵<http://www.pearsonhighered.com/educator/academic/product/0,3110,0131496980,00.html>

⁷⁶<http://creativecommons.org/licenses/by/3.0/us/>

3.1.3.4.1 Download the library

As of September 2016, the library can be downloaded in a zip file named **bookClasses-3-9-10-with-doc.zip** at <http://home.cc.gatech.edu/TeaParty/47>.⁷⁷ Additional information is available at <http://coweb.cc.gatech.edu/mediaComp-plan/101>⁷⁸.

In order to work with the sample programs and assignments that use the library, you will need to download a copy of the zip file from the site listed above. To guard against the possibility of that link becoming broken at some point in the future, I am depositing a backup copy of the zip file containing the library on the cnx.org site and you can download it here⁷⁹.

3.1.3.4.2 Prepare the library for use

Once you have downloaded the zip file, you will need to extract the folder named **bookClasses** from the zip file and store it as a folder in the root of your C-drive. The path to the library will then be:

```
C:\bookClasses
```

Once you have stored the **bookClasses** folder on your C-drive as described above, **DO NOT** do anything that will modify the contents of the folder. For example, don't try to compile the source code in the library. The source code in the library has already been compiled. The library is completely ready for use as received in the download.

3.1.3.4.3 Library documentation

When you examine the contents of the **bookClasses** folder, you will see that in addition to source code and compiled class files for the library, the folder also contains **javadoc** documentation for the library in a folder named **doc** and some other material as well. Go to the **doc** folder and open the file named **index.html** in your browser to view the documentation.

3.1.3.4.4 Compile and run a graphics program with a single source code file

This section will demonstrate how to use the multimedia library to create and display a simple graphics window.

Create an empty folder named **Hello03** on your C-drive.

Create a Java source code file named **Hello03.java** containing the code shown in Listing 8 (p. 292) and store the file in the folder named **Hello03**.

Listing 8 . Source code for the class named Hello03.

```
import java.awt.Color;

class Hello03{
    public static void main(String[] args){
        Picture pix = new Picture(300,100);
        pix.setAllPixelsToAColor(Color.RED);
        pix.addMessage("Hello World from Hello03",50,50);
        pix.explore();
    } // end main
} //end class
```

⁷⁷<http://home.cc.gatech.edu/TeaParty/47>.

⁷⁸<http://coweb.cc.gatech.edu/mediaComp-plan/101>

⁷⁹<http://cnx.org/content/m63123/latest/bookClasses-3-9-10-with-doc.zip>

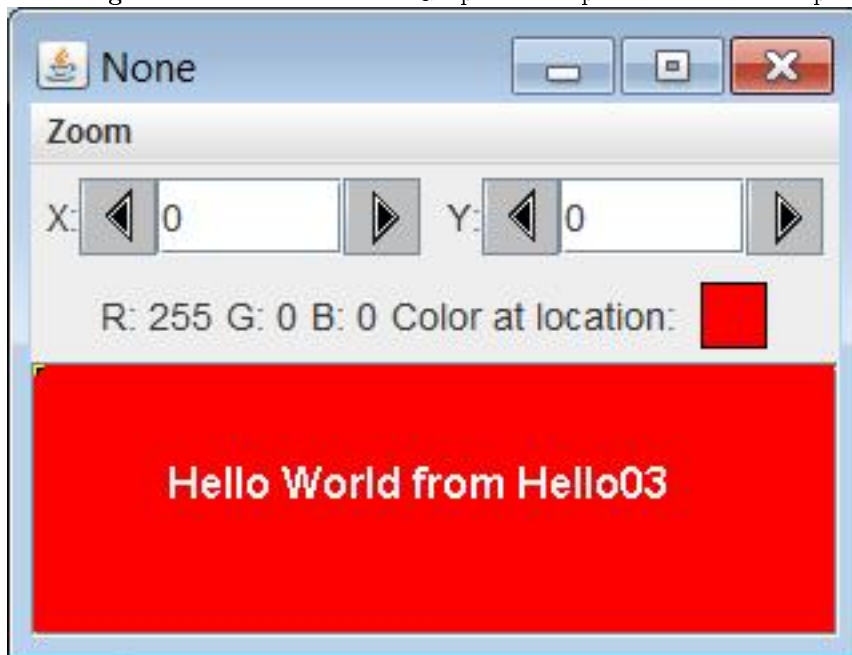

Create a batch file named **Hello03.bat** containing the commands shown in Listing 9 (p. 293) . Store the batch file in the folder named **Hello03** .

Listing 9 . Commands for the batch file named Hello03.bat.

```
echo off
"C:\Program Files\Java\jdk1.8.0_101\bin"\javac -cp .;C:\bookClasses Hello03.java
"C:\Program Files\Java\jdk1.8.0_101\bin"\java -cp .;C:\bookClasses Hello03
```

Double click the batch file. As before, a black command-line window will appear on your screen. In this case, however, there is nothing interesting in the command-line window. The interesting output will appear on your screen in the form of a graphics window as shown in Figure 5 (p. 293) .

Figure 5. Graphic output from the program named Hello03.

If you click the large X in the upper-right corner of the window, both the graphics window and the black command-line window should disappear from your screen.

3.1.3.4.5 Compile and run a graphics program with two source code files and an image file

Now I will show you how to write, compile, and execute a slightly more complex graphics program consisting of two Java source code files and an image file.

Begin by creating an empty folder named **Hello04** on your C-drive.

Click here ⁸⁰ to download a zip file containing an image file named **Hello04-a.jpg** . Extract and save the image file in the folder named **Hello04** .

Create a Java source code file named **Hello04.java** containing the code shown in Listing 10 (p. 293) . Save the file in the folder named **Hello04** .

Listing 10 . Source code for the class named Hello04.

⁸⁰<http://cnx.org/content/m63123/latest/Hello04-a.zip>

```
class Hello04{
    public static void main(String[] args){
        new Hello04Runner().run();
    }// end main
}//end class
```

Create another Java source code file named **Hello04Runner.java** containing the code shown in Listing 11 (p. 294) . Save the file in the folder named **Hello04** .

Listing 11 . Source code for the class named Hello04Runner.

```
class Hello04Runner{
    void run(){
        Picture pix = new Picture("Hello04-a.jpg");
        pix.addMessage("Hello World from Hello04",100,100);
        pix.explore();
    }// end main
}//end class
```

Using your path, create a batch file named **Hello04.bat** containing the commands shown in Listing 12 (p. 294) . Save the file in the folder named **Hello04** .

Listing 12 . Commands for the batch file named Hello04.bat.

```
echo off
"C:\Program Files\Java\jdk1.8.0_101\bin"\javac -cp .;C:\bookClasses Hello04.java
"C:\Program Files\Java\jdk1.8.0_101\bin"\java -cp .;C:\bookClasses Hello04
```

Double click the batch file. As before, a black command-line window will appear on your screen. Also as before, there is nothing interesting in the command-line window. The interesting output will appear on your screen in the form of a graphics window as shown in Figure 6 (p. 294) .

Figure 6. Graphic output from the program named Hello04.

That is the end of the configuration procedure. If you have been successful in carrying out all of these instructions, given the source code, you should now be able to compile and execute the code for any program involved in this course that uses Ericson's multimedia library. Of course, writing that source code is another matter altogether.

3.1.3.5 Running pre-compiled programs

There are a couple more basic skills that students need in order to successfully complete this course.

- Students need to be able to run pre-compiled programs when provided the class files and images files required by the program.

- Students need to be able to run two different Java programs and compare the output text and/or graphic images produced by the two programs.

This section will deal with the first of those two skills. The second skill will be dealt with in the next section.

Begin by creating a new empty folder named **Hello05** .

Click here ⁸¹ to download a zip file named **Hello05.zip** . The zip file contains the following three files, which are the files required to run a pre-compiled program named **Hello05** .

- Hello05.class
- Hello05Runner.class
- Hello05-a.jpg

Extract the contents of the zip file and store them in the folder named **Hello05** ..

Create a batch file named **RunHello05.bat** containing the commands shown in Listing 13 (p. 296) . Store the batch file in the folder named **Hello05** . (*Note that unlike the previous batch files, this batch file does not execute the compiler program named **javac** .*)

Listing 13 . Commands for the batch file named RunHello05.bat.

```
echo off
"C:\Program Files\Java\jdk1.8.0_101\bin"\java -cp .;C:\bookClasses Hello05
```

Double click the batch file to run the program. The output should be as shown in Figure 7 (p. 296) .

Figure 7. Graphic output from the program named Hello05.

⁸¹<http://cnx.org/content/m63123/latest/Hello05.zip>

3.1.3.6 Compare the graphic output from each of two Java programs

Follow the procedure described here (p. 293) to compile and run the program named **Hello04** producing the graphic output shown in Figure 6 (p. 294) . The graphic output will appear in the upper-left corner of the screen.

Using the mouse, grab the output window by the banner at the top and drag it to the right side of the screen.

Follow the procedure described here (p. 295) to run the program named **Hello05** producing the graphic output shown in Figure 7 (p. 296) . The graphic output will appear in the upper-left corner of the screen.

Using the mouse, drag the windows and position them side-by-side on your screen as shown in Figure 8 (p. 298) . Visually compare the images to see if they match.

Figure 8. Compare the graphic output images from two Java programs.

You may also find it useful to position the windows one above the other, depending on which aspect of the images you need to compare.

Viewing content (*such as this Ebook*) on OpenStax CNX ⁸⁶ doesn't require a login. However, if you create a free account, that will allow you to activate the Email notification feature and to access some other features as well.

Click here ⁸⁷ to request a free OpenStax CNX ⁸⁸ account. (*Note that access to some of the features granted by an account require access to the legacy server, which may be slower than you are accustomed to.*)

3.1.4.4 Activating the Email notification

When you create your account, a default lens named **My Favorites** will be automatically created for the account. Although you can create other lenses with different names, that isn't necessary to activate the Email notification feature.

The following instructions assume that you have created an account and you are viewing one of my Ebooks such as *ITSE 2321 - Object-Oriented Programming (Java)* ⁸⁹ .

Begin by selecting the link titled **CNX Author | Legacy Site** in the upper-right corner of any page in the Ebook. For the example of the Ebook titled ITSE 2321 - Object-Oriented Programming (Java)⁹⁰, selecting that link should cause you to land on a page that displays the same page of the same Ebook in the legacy format. (Note that an Ebook is called a Collection in the legacy format.)

The page that you land on will have the following tabs at the top of the page:

- Home
- Content
- Lenses
- About Us
- Help
- MyCNX

Select the tab labeled **MyCNX**. You will land on your home page in the authoring section of the website under the tab labeled **MyCNX**.

If you are not already logged in, you will land on a page asking you to log in. Go ahead and log in using the account that you created earlier. After logging in, you will land on your home page in the authoring section of the website under the tab labeled **MyCNX**.

Select the link labeled **Lenses** in the upper-left portion of the page. You will see a list of any lenses that you have created plus the default lens named **My Favorites**. Select the **edit** link next to the link for the lens named **My Favorites**. You should land on a page containing a tab labeled **Edit lens properties**. Select that tab to edit the properties of the **My Favorites** lens.

Check the box labeled **Receive e-mails when any content included in this lens is changed**. Then select the button labeled **Save** at the bottom of the page. You are now registered to receive Email notifications when the contents of your favorite Ebooks change.

Note that this capability is not restricted to this Ebook. As of October 2016, you can use this procedure to register for Email notifications of changes to any Ebook published on OpenStax CNX⁹¹, including the open textbooks such as College Physics⁹².

3.1.4.5 Adding Ebooks to the list of your favorite Ebooks

Once you have completed the registration described above, if you are viewing a page in an Ebook and you want to add the Ebook to your **My Favorites** lens,

- Select the CNX Author | Legacy Site link in the upper-right corner of the page.
- Select the link labeled **Add to Favorites** at the top of the page that you land on.

At that point, you can add the page or the entire Collection (*Ebook*) to the lens.

Having added the Ebook or page to the lens, you will receive an Email message notifying you when that material is modified and republished. The Email message identifies the page and provides some other information as well.

Please be aware that whenever I modify a page, I sometimes require several cycles of check-out/modify/upload/publish before I am satisfied with the modified version. In such a situation, you may receive several Email messages in succession.

3.1.4.6 Deactivating Email notification

If you decide that you don't want to receive Email notifications, you can repeat the process described above and remove the check from the box labeled **Receive e-mails when any content included in this lens is changed**.

Or, you could go to your **MyCNX** page, select the link to **Lenses**, select the **edit** link for the **My Favorites** lens, check the box next to the troublesome item, and select the **Remove from lens** button.

3.2.1.2 Preface

This module is the first in a series of modules designed to teach you about the essence of Object-Oriented Programming (OOP) using Java.

3.2.1.2.1 The essence of OOP

My dictionary provides several definitions for the word essence. Among those definitions are the following:

- The property necessary to the nature of a thing
- The most significant property of a thing

Thus, this miniseries will describe and discuss the necessary and most significant aspects of OOP using Java. In other words, I will discuss the essence of OOP using Java. For the first few modules, I will provide that information in a high-level format, devoid of any requirement to understand detailed Java syntax. In those cases where an understanding of Java syntax is required, I will provide the necessary syntax information in the form of supplementary notes.

Therefore, if you have a general understanding of computer programming, you should be able to read and understand the modules in this miniseries, even if you don't have a strong background in the Java programming language.

3.2.1.2.2 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the listings while you are reading about them.

3.2.1.2.2.1 Listings

- Listing 2 (p. 308) . Calling the playStation method.

3.2.1.3 Preview

In order to understand OOP, you need to understand the following three concepts:

- Encapsulation
- Inheritance
- Polymorphism

This module will concentrate on encapsulation. Encapsulation will be used as a springboard for a discussion of objects.

A description of an object-oriented program will be provided, along with a description of an object, and how it relates to encapsulation.

In order to relate object-oriented programming to the real world, a car radio will be used to illustrate and discuss several aspects of software objects. For example, you will learn that car radios, as well as software objects, have the ability to store data, along with the ability to modify or manipulate that data.

You will learn that car radios, as well as software objects, have the ability to accept messages and to perform an action, modify their state, return a value, or some combination of the above.

You will learn some of the jargon used in OOP, including persistence, state, messages, methods, and behaviors.

You will learn where objects come from, and you will learn that a class is a set of plans that can be used to construct objects. You will learn that a Java *object* is an *instance* of a *class*.

You will see a little bit of Java code, used to create an object, and then to send a message to that object (invoke a method on the object).

You will learn about Java references and reference variables. You will also learn a little about memory allocation for objects and variables in Java.

3.2.1.4 Discussion and sample code

Purpose of the miniseries

As mentioned earlier, I will describe and discuss the necessary and most significant aspects of OOP using Java.

The three pillars

Most books on OOP will tell you that in order to understand OOP, you need to understand the following three concepts:

- Encapsulation
- Inheritance
- Polymorphism

I agree with that assessment.

(Some books will also add abstraction and/or late binding to the list. I tend to think of those two topics as being included in one or more of the three concepts listed above.)

Begin with encapsulation

Generally, speaking, these three concepts increase in difficulty going down the list from top to bottom. Therefore, I will begin with Encapsulation and work my way down the list in successive modules.

What is an Object-Oriented Program?

Many authors would answer this question something like the following:

An Object-Oriented Program consists of a group of cooperating objects, exchanging messages, for the purpose of achieving a common objective.

What is an object?

An object is a software construct that encapsulates data, along with the ability to use or modify that data, into a software entity.

What is encapsulation?

An interesting description of encapsulation was provided in an article by Rocky Lhotka regarding VB.NET. That description reads as follows:

"Encapsulation is the concept that an object should totally separate its interface from its implementation. All the data and implementation code for an object should be entirely hidden behind its interface.

The idea is that we can create an interface (Public methods in a class) and, as long as that interface remains consistent, the application can interact with our objects. This remains true even if we entirely rewrite the code within a given method thus the interface is independent of the implementation."

I like this description, so I won't try to improve on it. However, I will try to illustrate it in the paragraphs that follow.

A real-world analogy

Abstract concepts, such as the concept of an object or encapsulation, can often be best understood by comparing them to real-world analogies. One imperfect, but fairly good analogy to a software object is the radio in your car.

The ability to store data

Your car radio probably has the ability to store data, and to allow you to use and modify that data at will. *(However, you can only use and modify that data through use of the human interface that is provided by the manufacturer of the radio.)*

The data that can be stored in your car radio probably includes a list of five or more frequencies that correspond to your favorite radio stations.

Using the stored data

The radio provides a mechanism (*human interface*) that allows you to use the data stored therein.

When you press one of the frequency-selector buttons on the front of the radio, the radio automatically tunes itself to the frequency corresponding to that button. *(In this case, you, the user, are sending a message to the radio object asking it to perform a particular action.)*

If you have previously stored a favorite frequency in the storage location corresponding to that button, pressing the button (*sending the message*) will cause the radio station transmitting at that frequency to be heard through the radio's speakers.

If you have not previously stored a favorite frequency in the storage location corresponding to that button, you will probably only hear static. *(That doesn't mean that the radio object failed to respond correctly to the message. It simply means that its response was based on bad data.)*

Modifying the stored data

The human interface also makes it possible for you to store or modify those five or more frequency values. This is done in different ways for different radios. On my car radio, the procedure is:

- Manually tune the radio to the desired frequency
- Press one of the buttons and hold it down for several seconds.

When the radio beeps, I know that the new frequency value has been stored in a storage location that corresponds to that particular button.

Please change your state

What I have done here is to send a message to the radio object asking it to change its state. The beep that I hear could be interpreted as the radio object returning a value back to me indicating that the mission has been accomplished. *(Alternately, we might say that the radio object sent a message back to me.)*

We say that an object has changed its state when one or more data values stored in the object have been modified.

We also say that when an object responds to a message, it will usually perform an action, change its state, return a value, or some combination of the above.

Please perform an action

Following this, when I press that button (*send a message*), the radio object will be automatically tuned to that frequency.

Historical note: While the ability to cause your car radio to remember your list of favorite stations may seem like a miracle of modern digital electronics, the truth is that radios had this capability long before they contained digital electronics. My first car had a radio that accomplished this feat using strings, pulleys, and levers.

As I recall, in order to set the frequency for a button, I had to manually tune the radio to a station by turning a knob, pull one of the buttons out about a quarter of an inch, and then push it in again. From that point until I did the same thing again, whenever I pressed that button, some kind of a

mechanical contraption caused a big rotary capacitor to turn just the right amount to tune for a particular radio station.

Also, I remember my grandfather having a table-model radio in the early 1940's that had radio buttons. He used them to select his favorite stations, as he surfed the airwaves.

(Interestingly, the term radio button has now become a part of programming jargon, signifying certain visual components used in graphical user interfaces.)

Enough of that, now back to my modern car radio

If I drive to Dallas and press a button that I have associated with a particular radio station in Austin, I will probably hear static. In that case, I may want to change the frequency value associated with that button. I can follow the same procedure described earlier to *set* the frequency value associated with that button to correspond to one of the radio stations in Dallas. *(Again, I would be sending a message to the radio object asking it to change its state.)*

Jargon

As you can see from the above discussion, the world of OOP is awash with jargon, and the ability to translate the jargon is essential to an understanding of the published material on OOP. Therefore, as we progress through this series of modules, I will introduce you to some of that jargon and try to help you understand the meaning of the jargon.

Persistence

The ability of your car radio to remember your list of favorite stations is often referred to as persistence. An object that has the ability to store and remember values is often said to have persistence.

State

It is often said that the *state* of an object at a particular point in time is determined by the values stored in the object. In our analogy, even if we own identical radios, unless the two of us have the same list of favorite radio stations, associated with the same combination of buttons, the state of your radio object at any particular point in time will be different from the state of my radio object.

Identical objects with identical states: It is perfectly OK for the two of us to own identical radios and to cause the two radio objects to contain the same list of frequencies. Even if two objects have the same state at the same time, they are still separate and distinct objects. While this is obvious in the real world of car radios, it may not be quite as obvious in the virtual world of computer programming.

Sending a message

A person who speaks in OOP-speak might say that pressing one of the frequency-selector buttons on the front of the radio sends a message to the radio object, asking it to perform an action (*tune to a particular station*) . That person might also say that storing a new frequency that corresponds to a particular button entails sending a message to the radio object asking it to change its state.

Invoking or calling a method

Java-speak is a little more specific than general OOP-speak. In Java-speak, we might say that pressing one of the selector buttons on the front of the radio invokes or calls a method on the radio object. The behavior of the method is to cause the object to perform an action.

As a practical matter, the physical manifestation of sending a message to an object in Java is to cause that object to execute one of its methods.

Similarly, we might say that storing a new frequency that corresponds to a particular button invokes a *setter* method on the radio object.

(In an earlier paragraph, I said that I could follow a specific procedure to set the frequency value associated with a button to correspond to one of the radio stations in Dallas. Note the use of the words set and setter in this jargon.)

Behavior

In addition to state, objects are often also said to have *behavior* . The overall behavior of an object is determined by the combined behaviors of its individual methods.

For example, one of the behaviors exhibited by our radio object is the ability to play the radio station at a particular frequency. When a frequency is selected by pressing a selector button, the radio knows how to translate the radio waves at that frequency into audio waves compatible with our range of hearing, and to send those audio waves out through the speakers.

Thus, the radio object behaves in a specific way in response to a message asking it to tune to a particular frequency.

Where do objects come from?

In order to mass-produce car radios, someone must first create a set of plans, (*drawings, or blueprints*) for the radio. Once the plans are available, the manufacturing people can produce millions of nearly identical radios.

A class definition is a set of plans

The same is true for software objects. In order to create a software object in Java, it is necessary for someone to first create a plan.

In Java, we refer to that plan as a *class* .

The class is defined by a Java programmer. Once the class definition is available, that programmer, (*or other programmers*) , can use it to produce millions of nearly identical objects.

(*While millions may sound like a lot of objects, I'm confident that since Java was released into the programming world around 1997, Java programmers around the world have created millions of objects using the standard Java class named **Button** .*)

An instance of a class

If we were standing at the output end of the factory that produces car radios, we might pick up a brand new radio and say that it is an *instance* of the plans used to produce the radio. (*Unless they were object-oriented programmers, the people around us might think we were a little odd when they hear us say that.*)

However, it is common jargon to refer to a software object as an *instance of a class* .

To instantiate an object

Furthermore, somewhere along the way, someone turned the word instance into a verb, and it is also common jargon to say that when creating a new object, we are *instantiating* an object.

A little bit of code

It is time to view a little bit of Java code.

Assuming that you have access to a class definition, there are several different ways that you can create an object in Java. The most common way is using syntax similar to that shown in Listing 1 (p. 306) below.

Listing 1 . Instantiating a new Radio object.
<pre>Radio myObjRef = new Radio();</pre>

Table 3.1

What does this mean?

Technically, the expression on the right-hand side of the equal sign in Listing 1 (p. 306) applies the **new** operator to a *constructor* for the class named **Radio** in order to cause the new object to come into existence and to occupy memory.

(*Suffice it at this point to say that a constructor is code that assists in the creation of an object according to the plans contained in a class definition. The primary purpose of a constructor is to provide initial values for the new object, but the constructor is not restricted to that behavior alone.*)

A reference to the object

The right-hand expression in Listing 1 (p. 306) returns a *reference* to the new object.

What can you do with a reference?

The reference can later be used to send messages to the new object (*call methods belonging to the new object*) .

Saving the reference

In order to use the reference later, it is necessary to save it for later use.

The expression on the left-hand side of the equal sign in Listing 1 (p. 306) declares a variable of the type **Radio** named **myObjRef** .

(*Because this type of variable will ultimately be used to store a reference to an object, we often refer to it by the term **reference variable** .*)

What does this mean?

Declaring a variable causes memory to be set aside for use by the variable. Values can then be stored in that memory space and accessed later by calling up the name given to the variable when it was declared.

Assignment of values

The equal sign in Listing 1 (p. 306) causes the object's reference returned by the right-hand expression to be assigned to, or saved as a value in, the reference variable named **myObjRef** (*created by the left-hand expression*) . In Java, we refer to the equal sign (=) as the assignment operator.

Memory allocation

Once the code in Listing 1 (p. 306) has finished execution, two distinct and different chunks of memory have been allocated and populated.

One (*potentially large*) chunk of memory has been allocated (*by the right-hand expression*) to contain the object itself. This chunk of memory has been populated according to the plans contained in the definition of the class named **Radio** .

The other chunk of memory is a relatively small chunk allocated (*by the left-hand expression*) for the reference variable containing the reference to the object.

Calling a method on the object

Assume that the definition of the **Radio** class defines a method with the following format (*also assume that this method is intended to simulate pressing a frequency-selector button on the front of the radio*) :

```
public void playStation(int stationNumber)
```

What does this mean?

Generally, in our radio-object context, this format implies that the behavior of the method named **playStation** will cause the specific station identified by an integer value passed as **stationNumber** to be selected for play.

Public and void

The *void* return type means that the method doesn't return a value.

The *public* modifier means that the button can be pressed by anyone in the car who can reach it.

(*Car radios don't have frequency-selector buttons corresponding to the private modifier in Java.*)

The method signature

Continuing with our exposure of jargon, some authors would say that the following constitutes the *method signature* for the method identified above:

```
playStation(int stationNumber)
```

A little more Java code

Listing 2 (p. 308) shows the code from the earlier listing, expanded to cause the method named **playStation** to be called.

Listing 2 . Calling the playStation method.

```

    Radio myObjRef = new Radio();
myObjRef.playStation(3);

```

Table 3.2

The first statement in Listing 2 (p. 308) is a repeat of the statement from the earlier listing. It is repeated here simply to maintain continuity.

Method invocation syntax

The second statement in Listing 2 (p. 308) is new.

This statement shows the syntax used to send a message to a Java object, or to call a method on that object (*depending on whether you prefer OOP-speak or Java-speak*) .

Join the method name to the reference

The syntax required to call a method on a Java object joins the name of the method to the object's reference, using a period as the joining operator.

(*In this case, the object's reference is stored in the reference variable named **myObjRef** . However, there are cases where an object's reference may be created and used in the same expression without storing it in a reference variable. We often refer to such an object as an anonymous object.*)

Pressing a radio button

Given the previous discussion, the numeric value 3, passed to the method when it is called, simulates the pressing of the third button on the front of the radio (*or the fourth button if you elect to number your buttons 0, 1, 2, 3, 4, 5*) .

3.2.1.5 Summary

3.2.2.3 Preview

This module will concentrate primarily on a discussion of the Java **class** .

A simple Java program will be discussed to illustrate the definition and use of two different classes. Taken in combination, these two classes simulate the manufacture and the use of the car radio object discussed in an earlier module.

You will see how to write code to create a new **Radio** object by applying the **new** operator to the class named **Radio** . You will also see how to save that object's reference in a reference variable of type **Radio** .

You will see how to write code that is used to simulate the association of a radio button with a particular radio station.

You will see how to write code that is used to simulate the pressing of a radio button to play the radio station associated with that button.

You will see the definition of a class named **Radio01** . This class consists simply of the **main** method. The **main** method of a Java application is executed by the Java Virtual Machine when the application is run. Thus, it is the driver for the entire application.

You will see the definition of a class named **Radio** . This class includes one instance variable and two instance methods.

(The instance variable is a reference variable that refers to a special kind of object that I refer to as an array object. I will provide a very brief discussion on array objects in this module. I will have more to say about array objects in a subsequent module.)

I will also provide a short discussion of class variables, which are not used in this program. I will explain that the use of class variables can often lead to undesirable side effects.

Finally, I will provide a very brief discussion of the syntax of a simple class definition in Java.

3.2.2.4 Discussion and sample code

What is a class?

I explained in an earlier module that a class is a plan from which many objects can be created. I likened the class definition to the plans from which millions of nearly identical car radios can be produced.

A simple Java program

In order to help you to get started on the right foot, and in support of future discussions, it will be advantageous to provide and discuss a simple Java program in this module.

The car radio example

Harking back to an earlier module, Listing 9 (p. 319) , near the end of this module, shows the code for a simple Java application that simulates the manufacture and use of a car radio.

Explain in fragments

In order to help you to focus specifically on important sections of code, I will explain the code for this program in fragments.

Top-level classes

This program contains two top-level class definitions. *(Java also supports inner classes as opposed to top-level classes. Inner classes will be explained in detail in subsequent modules in this series.)*

The class named Radio01

One of those class definitions, named **Radio01** , is shown in its entirety in Listing 1 (p. 311) . The other class named **Radio** will be discussed later.

Listing 1 . The class named Radio01.

```
public class Radio01{
public static void main(
                String[] args){
    Radio myObjRef = new Radio();
    myObjRef.setStationNumber(3,93.5);
    myObjRef.playStation(3);
} //end main
} //end class Radio01
```

Table 3.3

The class named **Radio01** consists simply of the **main** method. The **main** method of a Java application is executed by the Java Virtual Machine when the application is run. Thus, it is the driver for the entire application.

The driver class

The code in Listing 1 (p. 311) simulates the manufacturer of the radio and the use of the radio by the end user. Without getting into a lot of detail regarding Java syntax, I will further subdivide and discuss this code in the following listings.

Constructing a Radio object

As discussed in a previous module, the code in Listing 2 (p. 312) applies the **new** operator to the constructor for the **Radio** class, causing a new object to be created according to the plans specified in the class named **Radio**.

Listing 2 . Constructing a Radio object.
<pre>Radio myObjRef = new Radio();</pre>

Table 3.4

Saving a reference to the Radio object

Also as discussed in a previous module, the code in Listing 2 (p. 312) declares a reference variable of type **Radio** and stores the new object's reference in that variable.

Programming the radio buttons

The code in Listing 3 (p. 312) is new to this discussion. This statement simulates the process of associating a particular radio station with a particular button - programming a button on the radio.

As I explained in a previous module, this is accomplished for my car radio by manually tuning the radio to a desired station and then holding the radio button down until it beeps. You have probably done something similar to this to the radio in your car.

Listing 3 . Programming the radio buttons.
<pre>myObjRef.setStationNumber(3, 93.5);</pre>

Table 3.5

The statement in Listing 3 (p. 312) accomplishes the association of a simulated button to a simulated radio station by calling the method named **setStationNumber** on the reference to the **Radio** object. *(Recall that this sends a message to the object asking it to change its state.)*

The parameters passed to the method cause radio button number 3 to be associated with the frequency 93.5 MHz. *(The value 93.5 is stored in the variable that represents button number 3.)*

Sending a message to the object

Using typical OOP jargon, the statement in Listing 3 (p. 312) sends a message to the **Radio** object, asking it to change its state according to the values passed as parameters.

Pressing a button on the radio

Finally, the code in Listing 4 (p. 313) calls the method named **playStation** on the **Radio** object, passing the integer value 3 *(the button number)* as a parameter.

Listing 4 . Pressing a button on the radio.

```
myObjRef.playStation(3);
```

Table 3.6**Another message**

This code sends a message to the object asking it to perform an action. In this case, the action requested by the message is:

- Tune yourself to the frequency previously associated with button number 3
- Play the radio station that you find at that frequency through the speakers

How does this simulated radio play?

This simple program doesn't actually play music. As you will see later, this causes the message shown in Figure 1 (p. 313) to appear on the computer screen, simulating the selection and playing of a specific radio station.

Figure 1 . Screen output.

```
Playing the station at 93.5 Mhz
```

Table 3.7**The Radio class**

Listing 5 (p. 314) shows the class definition for the **Radio** class in its entirety.

Listing 5 . The Radio class .

```

class Radio{
//This class simulates the plans from
// which the radio object is created.
protected double[] stationNumber =
                new double[5];

public void setStationNumber(
                int index,double freq){
    stationNumber[index] = freq;
} //end method setStationNumber

public void playStation(int index){
    System.out.println(
        "Playing the station at "
        + stationNumber[index]
        + " Mhz");
} //end method playStation

} //end class Radio

```

Table 3.8

Note that the code in Listing 5 (p. 314) does not contain an explicit constructor. If you don't define a constructor when you define a new class, a default version of the constructor is provided on your behalf. That is the case for this simple program.

(Constructors will be explained in detail in subsequent modules.)

The plans for an object

The code in Listing 5 (p. 314) provides the plans from which one or more objects that simulate physical radios can be constructed.

An object instantiated (*an object is an instance of a class*) from the code in Listing 5 (p. 314) simulates a physical radio. I will subdivide this code into fragments and discuss it in the following listings.

An instance variable

In a previous module, I explained that we often say that an object is an instance of a class. (*A physical radio is one instance of the plans used to produce it.*) The code in Listing 6 (p. 314) shows the declaration and initialization of what is commonly referred to as an *instance variable* .

Listing 6 . An instance variable.

```

protected double[] stationNumber =
                new double[5];

```

Table 3.9**Why call it an instance variable?**

The name instance variable comes from the fact that every instance of the class (*object*) has one. (Every radio produced from the same set of plans has the ability to associate a frequency with each selector button on the front of the radio.)

Class variables - an aside

Note that Java also supports something called a *class variable*, which is different from an instance variable.

Class variables are shared among all of the objects created from a given class. Stated differently, no matter how many objects are instantiated from a class definition, they all share a single copy of each class variable.

There is no analogy to a class variable in a physical radio object. Radios are installed in different cars separated from each other by thousands of miles. Therefore, there can be no sharing of anything among different physical radio objects.

(Well, that may not be entirely true. In today's technology, different radio objects could potentially share something at a common location via satellite communications, but my car radio doesn't do anything like that.)

Class variables can cause undesirable side effects

While class variables are relatively easy to use in Java, they are difficult to explain from an OOP viewpoint. Also, it is my opinion that from a good overall design viewpoint, class variables should be used very sparingly, if at all.

Therefore, for the first several modules, I will exclude the possibility of class variables in this series of modules. (I will explain the use of class variables in Java in a subsequent module.)

Reference to an array object

Now, let's get back to the instance variable named **stationNumber** shown in Listing 6 (p. 314). Without getting into a lot of detail, this variable is also a reference variable, referring to an array object.

The array object encapsulates a simple one-dimensional array with five elements of type **double**. (Java array indices begin with zero, so the index values for this array extend from 0 to 4 inclusive. I will also discuss array objects in more detail in a subsequent module.)

Persistence

The array object is where the data is stored that associates the frequency of a radio station with the simulated physical button on the front of the radio.

Each element in the array corresponds to one frequency-selector button on the front of the radio. Hence, the radio simulated by an object of the **Radio** class has five simulated frequency-selector buttons.

The array object exists when the code in Listing 6 (p. 314) has finished executing. Each element in the array has been automatically initialized to a value of 0.0 (*double-precision float value of zero*).

The setStationNumber method

Listing 7 (p. 315) shows the setStationNumber method in its entirety

Listing 7 . The setStationNumber method.

```
public void setStationNumber(
    int index,double freq){
    stationNumber[index] = freq;
} //end method setStationNumber
```

Table 3.10

Associates radio station with button

This is the method that is used to simulate the behavior of having the user associate a particular button with a particular radio station. (Recall that this is accomplished on my car radio by manually tuning the

radio to a specific station and then holding the button down until it beeps. Your car radio probably operates in some similar way.)

This method receives two incoming parameters:

- An integer that corresponds to a button number (*button numbers are assumed to begin with 0 and extend through 4 in order to match array indexes*)
- A frequency value to be associated with the indicated button.

Save the frequency value

The code in the method stores the frequency value in an element of the array object discussed earlier.

The element number is specified by the value of index shown in square brackets in the assignment expression. (*This syntax is similar to storing a value in an array element in most programming languages that I am familiar with.*)

Pressing a radio button to select a station

Listing 8 (p. 316) shows the `playStation` method. This is the method that simulates the result of having the user press a button on the front of the radio to select a particular radio station for play.

Listing 8 . The `playStation` method.

```
public void playStation(int index){
System.out.println(
    "Playing the station at "
    + stationNumber[index]
    + " Mhz");
} //end method playStation
```

Table 3.11

Selecting and playing a radio station

The method receives an integer index value as an incoming parameter. This index corresponds to the number of the button pressed by the user. This method simulates the playing of the radio station by

- extracting the appropriate frequency value from the array object, and
- displaying that value on the computer screen along with some surrounding text.

When called by code in the `main` method of this program, this method produces the message shown in Figure 1 (p. 313) on the computer screen

That summarizes the code and the behavior of this simple program.

Class definition syntax

There are a number of items that can appear in a class definition, including the following:

- Instance variables
- Class variables
- Instance methods
- Class methods
- Constructors
- Static initializer blocks
- Inner classes

Let's keep it simple

In order to make these modules as easy to understand as possible, the first several modules will ignore the possibility of class variables, class methods, static initializer blocks, and inner classes.

As mentioned in the earlier discussion of class variables, these elements aren't particularly difficult to use, but they create a lot of complications when attempting to explain OOP from the viewpoint of Java programming.

Therefore, the first several modules in the series will assume that class definitions are limited to the following elements:

- Instance variables
- Instance methods
- Constructors

A constructor

A constructor is used only once in the lifetime of an object. It participates in the task of creating (*instantiating*) and initializing the object. Following instantiation, the state and behavior of an object depends entirely on instance variables, class variables, instance methods, and class methods.

Instance variables and methods

The class named **Radio** discussed earlier contains

- one instance variable named **stationNumber** , and
- two instance methods named **setStationNumber** and **playStation** .

3.2.2.5 Summary

This module has concentrated primarily on a discussion of the Java class.

A simple Java program was discussed to illustrate the definition and use of two different classes. Taken in combination, these two classes simulate the manufacture and use of the car radio object introduced in an earlier module.

You saw how to write code to create a new **Radio** object by applying the **new** operator to the class named **Radio** .

You also saw how to save that object's reference in a reference variable of type **Radio** .

You saw how to write code (*in an instance method named **setStationNumber***) used to simulate the association of a radio button with a particular radio station.

You saw how to write code (*in an instance method named **playStation***) to simulate the pressing of a radio button to play the radio station associated with that button.

You saw the definition of the class named **Radio01** , which consists simply of the **main** method. The **main** method of a Java application is executed by the Java Virtual Machine when the application is run.

You saw the definition of the class named **Radio** . This class includes one instance variable and two instance methods. (*The instance variable is a reference variable that refers to a special kind of object that I refer to as an array object. I provided a very brief discussion on array objects. I will have more to say on this topic in a subsequent module.*)

I provided a short discussion of class variables, which are not used in this program. I explained that the use of class variables can often lead to undesirable side effects.

Finally, I provided a very brief discussion of the syntax of a simple class definition in Java.

3.2.2.6 What's next?

Recall that in order to understand OOP, you must understand the following three concepts:

- Encapsulation
- Inheritance

- Polymorphism

The next module will begin a discussion of inheritance. Overall, the discussion of inheritance will require more than one module. In the next module, I will discuss how the definition of a class defines a new data type. I will show you how to extend an existing class. I will explain what is inherited through inheritance. I will discuss code reuse and explicit constructors.

Finally, I will illustrate all of the above in a simple program that extends the **Radio** class discussed in this module into a new class named **Combo** that simulates an upgraded radio containing a tape player. (*Yes, at one point in history, car radios did contain tape players.*)

3.2.3.3 Preview

Extending a class

This module shows you how to extend an existing class to create a new class. The new class is the blueprint for a new type.

Inheritance and code reuse

The existing class is often called the *superclass* and the new class is often called the *subclass*. This is the mechanism for class inheritance in Java. Inheritance provides a formal mechanism for code reuse.

The subclass inherits all of the variables and all of the methods defined in the superclass.

Although not explicitly demonstrated in this module, whenever you declare a reference variable whose type is defined by a class, that variable can be used to store references to objects instantiated from that class or instantiated from any subclass of that class. Furthermore, that reference can be used to call methods defined in or inherited into that class with no requirement for a cast. If the method is defined in that class and overridden in the subclass, and if the object is actually of the subclass type, the overridden version will be executed. This is polymorphism.

Car radios with tape players

A class from a previous module (*whose objects represent car radios*) is extended to define a new class, whose objects represent expanded car radios that contain tape players. (*Yes, at one point in history, car radios did contain tape players instead of CDs.*)

Sending messages to the object

Objects of the new class know how to respond to messages for inserting, playing, and removing a tape, in addition to those messages that are appropriate for objects of the original Radio class.

3.2.3.4 Discussion and sample code

The three pillars of OOP

In an earlier module, I explained that most books on OOP will tell you that in order to understand OOP, you must understand the following three concepts:

- Encapsulation
- Inheritance
- Polymorphism

I agree with that assessment.

Encapsulation

The first module in this series provided an explanation of encapsulation.

Inheritance

This module (*and some modules to follow*) will provide an explanation of inheritance. I will use another simple program to explain the concept of inheritance.

Polymorphism

Polymorphism is the most complex of the three, and will be explained in future modules.

A new data type

Whenever you define a class in Java, you cause a new data type to become available to the program. Therefore, whenever you need a new data type, you can define a new class to make that type available.

Extending a class

Defining a new class (*to create a new type*) can involve a lot of effort. Sometimes you have an option that can greatly reduce the effort required to create your new type. If a class (*type*) already exists that is close to what you need, you can often extend that class to produce a new class that is closer to what you need.

In many cases, this will require much less effort than that required to start from scratch and define a new class to establish a new type. The ability to extend one class into another new class is the *essence of inheritance*.

According to the current jargon, the new class is called the *subclass* and the class that is extended is called the *superclass* .

Although not explicitly demonstrated in this module, whenever you declare a reference variable whose type is defined by a class, that variable can be used to store references to objects instantiated from that class or instantiated from any subclass of that class. Furthermore, that reference can be used to call methods defined in or inherited into that class with no requirement for a cast. If the method is defined in that class and overridden in the subclass, and if the object is actually of the subclass type, the overridden version will be executed. This is polymorphism.

What is inherited?

The subclass inherits all of the variables and all of the methods defined in (or inherited into) the superclass, almost as if you had completely defined the new class from scratch, and had reproduced all of the code already defined in the existing superclasses.

Code reuse

Therefore, inheritance often makes it possible to define a new class with a minimum requirement to write new code by formally reusing the code that was previously written into the superclasses. Sometimes you can get by with simply extending the existing class.

Sometimes, however, it is also necessary to make changes to the existing class to improve its ability to be extended in a meaningful way. (*That is the case with the sample program discussed in this module, but the next module will show you how to avoid that issue.*) It all depends on how the existing class was designed in the first place. Ideally the original design of the class will be such that modification of the original class is not necessary.

The Radio class

A previous program defined a class named **Radio** . Objects instantiated from the **Radio** class (see the previous modules for a discussion of instantiating objects) were intended to simulate car radios. (*Note that the car radios simulated by objects of the **Radio** class didn't have built-in tape players.*)

The Combo class

In this module, I will use inheritance to extend the **Radio** class into a new class named **Combo** . Objects instantiated from the **Combo** class are intended to simulate car radios with a built-in tape player.

A complete listing of the new program is shown in Listing 9 (p. 331) near the end of the module.

Will discuss in fragments

As usual, I will discuss this program in fragments. I will begin my discussion with the definition of the new class named **Combo** . Then I will come back and discuss the class named **Radio** and the driver class named **Radio02** .

The combo class

The code in Listing 1 (p. 322) shows the beginning of the class named **Combo** .

Listing 1 . Beginning of the Combo class.

```
class Combo extends Radio{

public Combo(){//constructor
    System.out.println(
        "Combo object constructed");
} //end constructor
```

Table 3.13

Two new items

There are two new items in Listing 1 (p. 322) that you did not see in the code in the previous modules.

Combo extends Radio

First, the class named **Combo** *extends* the class named **Radio** . This means that an object instantiated from the **Combo** class will contain all of the variables and all the methods defined in the **Combo** class, plus all the variables and methods defined in the **Radio** class, and its superclasses. *(The variables and methods of the superclass are inherited into the subclass.)*

An explicit constructor

Second, the class named **Combo** defines an explicit constructor.

Defining a constructor is optional

When defining a new class, it is not necessary to define a constructor. If you don't define a constructor, a default constructor will be provided automatically.

Why define a constructor?

The intended purpose of a constructor is to initialize the instance variables belonging to the new object. However, constructors can do other things as well. In this case, I used an explicit constructor to display a message when the object is instantiated from the class named **Combo** .

Brief discussion of constructors

I'm not going to discuss constructors in detail at this point. However, I will give you a few rules regarding constructors.

- Constructors *(like methods)* can be overloaded. *(I will explain what overloading means in a subsequent module.)*
- The names of constructors must match the names of the classes in which they are defined.
- A constructor signature never indicates a return type *(such as void or double)* .
- The code in a constructor never contains a return statement.

Instance methods

The new class named **Combo** defines three instance methods, each of which has to do with the handling of tape in the tape player:

- insertTape
- removeTape
- playTape

(If you feel ambitious, you could upgrade this class even further to add features such as rewind, fast forward, pause, etc.).

The insertTape method

The entire method named **insertTape** is shown in Listing 2 (p. 323) . This is the method that is used to simulate the insertion of a tape by the user.

Listing 2 . The insertTape method.

```
public void insertTape(){
System.out.println("Insert Tape");
tapeIn = true;
System.out.println("  Tape is in");
System.out.println(
        "      Radio is off");
} //end insertTape method
```

Table 3.14

The most significant thing about the code in Listing 2 (p. 323) is the assignment of the `true` value to the `boolean` variable named `tapeIn`. Other than setting the value of the `tapeIn` variable to `true`, the code in Listing 2 (p. 323) simply prints some messages to indicate what is going on.

What is `tapeIn` used for?

As you will see shortly, the value of the variable named `tapeIn` is used to determine if it is possible to play the tape or to play the radio.

According to that logic:

- If `tapeIn` is true, it is possible to play the tape but it is not possible to play the radio.
- If `tapeIn` is false, it is possible to play the radio, but it is not possible to play the tape.

`tapeIn` is not declared in the `Combo` class

It is also worthy of note that in this version of the program, the variable named `tapeIn` is not declared in the `Combo` class (*this will change in the next module where the program uses method overriding*). Rather, this variable is inherited from the `Radio` class that is extended by the `Combo` class.

The `removeTape` method

The `removeTape` method of the `Combo` class is shown in Listing 3 (p. 324). Its behavior is pretty much the reverse of the `insertTape` method, so I won't discuss it further.

Listing 3 . The `removeTape` method.

```
public void removeTape(){
System.out.println("Remove Tape");
tapeIn = false;
System.out.println(
    " Tape is out");
System.out.println(
    " Radio is on");
} //end removeTape method\
```

Table 3.15

The `playTape` method

Listing 4 (p. 324) shows the method named `playTape` defined in the new `Combo` class.

Listing 4 . The `playTape` method .

```
public void playTape(){
System.out.println("Play Tape");
if(!tapeIn){ //tapeIn is false
System.out.println(
    " Insert the tape first");
}else{ //tapeIn is true
System.out.println(
    " Tape is playing");
} //end if/else
} //end playTape
```

Table 3.16

Confirm that the tape is ready

Calling the method named **playTape** can be thought of as sending a message to the **Combo** object asking it to play the tape. The code in the **playTape** method checks to confirm that the value stored in the **tapeIn** variable is **true** before executing the request to play the tape.

If **tapeIn** is **false** , an error message is displayed advising the user to insert the tape first.

If **tapeIn** is **true** , the method prints a message indicating that the tape is playing.

Modified Radio class

Listing 5 (p. 325) shows the definition of the modified version of the class named **Radio** .

Listing 5 . Modified Radio class.

```

class Radio{
protected double[] stationNumber =
                    new double[5];
protected boolean tapeIn = false;
//-----//

public void setStationNumber(
        int index,double freq){
    stationNumber[index] = freq;
    System.out.println("Button "
        + index + " programmed");
} //end method setStationNumber
//-----//

public void playStation(int index){
    System.out.println("Play Radio");
    if(!tapeIn){ //tapeIn is false
        System.out.println(
            " Playing the station at "
            + stationNumber[index]
            + " Mhz");
    }else{ //tapeIn is true
        System.out.println(
            " Remove the tape first");
    } //end if/else
} //end method playStation

} //end class Radio

```

The first significant change that was made to the class named **Radio** is shown in Listing 6 (p. 326) below.

```

Table 3.18

The statement in Listing 6 (p. 326) declares and initializes a new instance variable named **tapeIn** . As explained earlier, this instance variable is used to indicate whether or not a tape is inserted. (*The Combo class inherits this variable.*)

Earlier in this module, I explained how the **playTape** method of the **Combo** class uses this value to determine whether or not to attempt to play a tape.

Change to the playStation method

The significant change that was made to the method named **playStation** of the **Radio** class is shown in Listing 7 (p. 326) below.

Listing 7 . Change to the playStation method.

```
    if(!tapeIn){//tapeIn is false
    System.out.println(
        "  Playing the station at "
        + stationNumber[index]
        + " Mhz");
    }else{//tapeIn is true
    System.out.println(
        "  Remove the tape first");
    }//end if/else
```

Table 3.19**Check the tape status**

The code in Listing 7 (p. 326) uses **tapeIn** to check the tape status before attempting to tune the radio station and play the radio. If a tape is inserted, this method simply displays an error message instructing the user to remove the tape first.

So, what's the big deal with inheritance?

The fact that it was necessary for me to make changes to the class named **Radio** greatly reduced the benefit of inheritance in this case. However, even in this case, the use of inheritance eliminated the need for me to define a new class that reproduces all of the code in the class named **Radio** .

(*In the next module, I will explain the process of overriding methods. I will show you how to use method overriding to accomplish these same purposes by extending the **Radio** class, without any requirement to modify the code in the **Radio** class. That will be a much better illustration of the benefits of inheritance.*)

The driver class

The new driver class named **Radio02** is shown in Listing 8 (p. 327) .

Listing 8 . The class named Radio02.

```

    public class Radio02{
//This class simulates the
// manufacturer and the human user
public static void main(
                String[] args){
    Combo myObjRef = new Combo();
myObjRef.setStationNumber(3,93.5);
myObjRef.playStation(3);
myObjRef.insertTape();
myObjRef.playStation(3);
myObjRef.removeTape();
myObjRef.playStation(3);
myObjRef.playTape();
myObjRef.insertTape();
myObjRef.playTape();
myObjRef.removeTape();
myObjRef.playStation(3);
} //end main
} //end class Radio02

```

Table 3.20**New object of the Combo class**

The most significant change in this class (*relative to the driver class named **Radio01** in a previous module*) is the statement that instantiates a new object of the **Combo** class (*instead of the Radio class*)

All of the other new code in Listing 8 (p. 327) is used to send messages to the new object in order to exercise its behavior.

Program output

The **Combo** object responds to those messages by producing the screen output shown in Figure 1 (p. 328) .

Figure 1 . Program output.
<pre> Combo object constructed Button 3 programmed Play Radio Playing the station at 93.5 Mhz Insert Tape Tape is in Radio is off Play Radio Remove the tape first Remove Tape Tape is out Radio is on Play Radio Playing the station at 93.5 Mhz Play Tape Insert the tape first Insert Tape Tape is in Radio is off Play Tape Tape is playing Remove Tape Tape is out Radio is on Play Radio Playing the station at 93.5 Mhz </pre>

Table 3.21

An exercise for the student

As the old saying goes, I will leave it as an exercise for the student to correlate the messages in Listing 8 (p. 327) with the output shown in Figure 1 (p. 328) .

3.2.3.5 Summary

Extending an existing class often provides an easy way to create a new type. This is primarily true when an existing class creates a type whose features are close to, but not identical to the features needed in the new type.

When an existing class is extended to define a new class, the existing class is often called the *superclass* and the new class is often called the *subclass* .

The subclass inherits all of the variables and all of the methods defined in the superclass and its super-classes.

Although not explicitly demonstrated in this module, whenever you declare a reference variable whose type is defined by a class, that variable can be used to store references to objects instantiated from that class or instantiated from any subclass of that class. Furthermore, that reference can be used to call methods defined in or inherited into that class with no requirement for a cast. If the method is defined in that class and overridden in the subclass, and if the object is actually of the subclass type, the overridden version will be executed. This is polymorphism.

Inheritance provides a formal mechanism for code reuse.

This module modifies slightly, and then extends the **Radio** class from a previous module to define a new class named **Combo**. Objects of the **Combo** class simulate car radios that contain tape players. Objects of the **Combo** class know how to respond to messages for inserting, playing, and removing a tape, in addition to those messages appropriate for an object of the **Radio** class.

The changes that were required in the definition of the **Radio** class provide for the fact that it is not possible to play a radio station and to play a tape at the same time. This change was necessary because the original designer of the **Radio** class (*this author*) didn't design that class with the idea of extending it to include a tape player. This points out the importance of thinking ahead when defining a new class.

3.2.3.6 What's next?

In the next module, I will show you how to use *method overriding* to cause the behavior of a method inherited into a subclass to be appropriate for an object instantiated from the subclass.

I will also show you how to use method overriding to eliminate the above requirement to modify the **Radio** class before extending it.

The primary difference between this program and the program in the earlier module (*whose objects simulate car radios*) is the inclusion in this program of a new class named **Combo**. 3.2.4.3 Preview

This module builds on the previous module ¹⁰⁵ . It is recommended that you study that module before embarking on this module.

The program discussed in this module extends a **Radio** class to produce a new class that simulates an upgraded car radio containing a tape player.

Method overriding is used to modify the behavior of a method of the **Radio** class named **playStation** , to cause that method to behave appropriately when a tape has been inserted into the tape player.

3.2.4.4 Discussion and sample code

Inheriting methods and variables

When you define a class that extends another class, an object instantiated from your new class will contain all of the methods and all of the variables defined in your new class. The object will also contain all of the methods and all of the variables defined in all of the superclasses of your new class.

The behavior of the methods

The behavior of the methods defined in a superclass and inherited into your new class may, or may not, be appropriate for an object instantiated from your new class. If those methods are appropriate, you can simply leave them alone.

Overriding to change behavior

If the behavior of one or more methods defined in a superclass and inherited into your new class is not appropriate for an object of your new class, you can change that behavior by *overriding* the method in your new class.

How do you override a method?

To override a method in your new class, simply reproduce the name, argument list, and return type of the original method in a new method definition in your new class. Then provide a body for the new method. Write code in that body to cause the behavior of the overridden method to be appropriate for an object of your new class.

Here is a more precise description of method overriding taken from the excellent book entitled *The Complete Java 2 Certification Study Guide* , by Roberts, Heller, and Ernest:

"A valid override has identical argument types and order, identical return type, and is not less accessible than the original method. The overriding method must not throw any checked exceptions that were not declared for the original method."

Any method that is not declared **final** can be overridden in a subclass.

Overriding versus overloading

Don't confuse method *overriding* with method *overloading* . Here is what Roberts, Heller, and Ernest have to say about overloading methods:

"A valid overload differs in the number or type of its arguments. Differences in argument names are not significant. A different return type is permitted, but is not sufficient by itself to distinguish an overloading method."

Car radios with built-in tape players

This module presents a sample program that duplicates the functionality of the program named **Radio02** discussed in the previous module. A class named **Radio** is used to define the specifics of objects intended to simulate car radios.

A class named **Combo** extends the **Radio** class to define the specifics of objects intended to simulate improved car radios having built-in tape players.

Modification of the superclass

In the program named **Radio02** in the previous module, it was necessary to modify the superclass before extending it to provide the desired functionality. *(The requirement to modify the superclass before extending it seriously detracts from the benefits of inheritance.)*

No superclass modification in this module

¹⁰⁵<http://cnx.org/contents/dzOvxPFw:ZMA3cfBy>

The sample program (named **Radio03**) in this module uses method overriding to provide the same functionality as the previous program named **Radio02** , without any requirement to modify the superclass before extending it. (Thus this program is more representative of the benefits available through inheritance than was the program in the previous module.)

Overridden playStation method

In particular, a method named **playStation** , defined in the superclass named **Radio** , is overridden in the subclass named **Combo** .

The original version of **playStation** in the superclass supports only radio operations. The overridden version of **playStation** defined in the subclass supports both radio operations and tape operations.

(The behavior of the version of **playStation** defined in the **Radio** class is not appropriate for an object of the **Combo** class. Therefore, the method was overridden in the **Combo** class to cause its behavior to be appropriate for objects instantiated from the **Combo** class.)

A complete listing of the program is shown in Listing 5 (p. 339) near the end of this module.

The class named Radio

As usual, I will discuss the program in fragments.

Listing 1 (p. 334) shows the superclass named **Radio** . This code is shown here for easy referral. It is identical to the code for the same class used in the program named **Radio01** discussed in an earlier module.

Listing 1 . The class named Radio.

```
class Radio{
protected double[] stationNumber =
                new double[5];

public void setStationNumber(
                int index,double freq){
    stationNumber[index] = freq;
} //end method setStationNumber

public void playStation(int index){
    System.out.println(
        "Playing the station at "
        + stationNumber[index]
        + " Mhz");
} //end method playStation

} //end class Radio
```

Table 3.23

Will override playStation

The class named **Combo** (discussed below) will extend the class named **Radio** . The method named **playStation** , shown in Listing 1 (p. 334) , will be overridden in the class named **Combo** .

If you examine the code for the **playStation** method in Listing 1 (p. 334) , you will see that it assumes radio operations only and doesn't support tape operations. That is the reason that it needs to be overridden. (For example, it doesn't know that it should refuse to play a radio station when a tape is being played.)

The Combo class

Listing 2 (p. 335) shows the beginning of the class definition for the class named **Combo** . The **Combo** class extends the class named **Radio** .

Listing 2 . Beginning of the Combo class.

```

class Combo extends Radio{

private boolean tapeIn = false;
//-----//

public Combo(){//constructor
    System.out.println(
        "Combo object constructed");
}//end constructor
//-----//

```

Table 3.24**The tapeIn variable**

The most important thing about the code in Listing 2 (p. 335) is the declaration of the instance variable named **tapeIn** .

(In the program named *Radio02* in the previous module, this variable was declared in the class named **Radio** and inherited into the class named **Combo** . That was one of the undesirable changes required for the class named **Radio** in that module.)

In this version of the program, the variable named **tapeIn** is declared in the subclass instead of in the superclass. Thus, it is not necessary to modify the superclass before extending it.

The constructor

The constructor in Listing 2 (p. 335) is the same as in the previous program named **Radio02** , so I won't discuss it further.

The overridden playStation method

The overridden version of the method named **playStation** is shown in Listing 3 (p. 335) . As you can see, this version of the method duplicates the signature of the **playStation** method in the superclass named **Radio** , but provides a different body.

Listing 3 . The overridden playStation method.

```

public void playStation(int index){
System.out.println("Play Radio");
if(!tapeIn){//tapeIn is false
    System.out.println(
        "    Playing the station at "
        + stationNumber[index]
        + " Mhz");
}else{//tapeIn is true
    System.out.println(
        "    Remove the tape first");
}
}
}

```

Table 3.25

Aware of the tape system

This overridden version of the `playStation` method in Listing 3 (p. 335) is aware of the existence of the tape system and behaves accordingly.

Depending on the value of the variable named `tapeIn`, this method will either

- tune and play a radio station, or
- display a message instructing the user to remove the tape.

Which version of `playStation` is executed?

When the `playStation` method is called on an object of the `Combo` class, the overridden version of the method (*and not the original version defined in the superclass named `Radio`*) is the version that is actually executed.

Although not particularly obvious in this example, this is one of the important characteristics of *runtime polymorphism*. When a method is called on a reference to an object, it is the type of the object (*and not the type of the variable containing the reference to the object*) that is used to determine which version of the method is actually executed.

Three other instance methods

The subclass named `Combo` defines three other instance methods:

- `insertTape`
- `removeTape`
- `playTape`

The code in these three methods is identical to the code in the methods having the same names in the program named `Radio02` in the previous module. I discussed that code in the previous module and won't repeat that discussion here. You can view those methods in the complete listing of the program shown in Listing 5 (p. 339) near the end of this module.

The driver class

Listing 4 (p. 336) shows the code for the driver class named `Radio03`.

Listing 4 . The driver class.

```
public class Radio03{
//This class simulates the
// manufacturer and the human user
public static void main(
        String[] args){
    Combo myObjRef = new Combo();
    myObjRef.setStationNumber(3,93.5);
    myObjRef.playStation(3);
    myObjRef.insertTape();
    myObjRef.playStation(3);
    myObjRef.removeTape();
    myObjRef.playStation(3);
    myObjRef.playTape();
    myObjRef.insertTape();
    myObjRef.playTape();
    myObjRef.removeTape();
    myObjRef.playStation(3);
} //end main
} //end class Radio03
```

Table 3.26

The code in Listing 4 (p. 336) is also identical to the code in the program named **Radio02** discussed in the previous module. Therefore, I won't discuss it in detail here.

A new object of the Combo class

I present this code here solely to emphasize that this code instantiates a new object of the **Combo** class. This assures that the overridden version of the method named **playStation** will be executed by the statements in Listing 4 (p. 336) that call the **playStation** method.

*(Although it is not the case in Listing 4 (p. 336) , even if the reference to the object of type **Combo** had been stored in a reference variable of type **Radio** , instead of a reference variable of type **Combo** , calling the **playStation** method on that reference would have caused the overridden version of the method to have been executed. That is the essence of runtime polymorphism based on overridden methods in Java.)*

Program output

This program produces the output shown in Figure 1 (p. 337) on the computer screen.

Figure 1 . Program output.
<pre> Combo object constructed Play Radio Playing the station at 93.5 Mhz Insert Tape Tape is in Radio is off Play Radio Remove the tape first Remove Tape Tape is out Radio is on Play Radio Playing the station at 93.5 Mhz Play Tape Insert the tape first Insert Tape Tape is in Radio is off Play Tape Tape is playing Remove Tape Tape is out Radio is on Play Radio Playing the station at 93.5 Mhz </pre>

Table 3.27

I will leave it as an exercise for the student to compare this output with the messages sent to the object by the code in Listing 4 (p. 336) .

3.2.4.5 Summary

An object instantiated from a class that extends another class will contain all of the methods and all of the variables defined in the subclass, plus all of the methods and all of the variables inherited into the subclass.

The behavior of methods inherited into the subclass may not be appropriate for an object instantiated from the subclass. You can change that behavior by overriding the method in the definition of the subclass.

To override a method in the subclass, reproduce the name, argument list, and return type of the original method in a new method definition in the subclass. Make sure that the overridden method is not less accessible than the original method. Also, make sure that it doesn't throw any checked exceptions that were not declared for the original method.

Provide a body for the overridden method, causing the behavior of the overridden method to be appropriate for an object of the subclass. Any method that is not declared **final** can be overridden in a subclass. The program discussed in this module extends a **Radio** class to produce a subclass that simulates an upgraded car radio containing a tape player.

Method overriding is used to modify the behavior of an inherited method named **playStation** to cause that method to behave appropriately when a tape has been inserted into the radio.

Method *overriding* is different from method *overloading*. Method *overloading* will be discussed in the next module.

3.2.4.6 What's next?

In the next module, I will explain the use of overloaded methods for the purpose of achieving compile-time polymorphism.

3.2.5.3 Preview

Previous modules introduced *overloading* and *overriding* methods. This module concentrates on the use of method overloading to achieve *compile-time polymorphism* .

Every class in Java is a direct or indirect subclass of the class named **Object** . Methods defined in the class named **Object** are inherited into all other classes. Inherited methods that are not declared **final** may be overridden to make their behavior more appropriate for objects instantiated from the new class.

Overloaded methods have the same name and different formal argument lists. They may or may not have the same return type.

Polymorphism manifests itself in Java in the form of multiple methods having the same name. This module concentrates on method overloading, sometimes referred to as *compile-time polymorphism* . Subsequent modules concentrate on method overriding, sometimes referred to as *runtime polymorphism* .

Overloaded methods may all be defined in the same class, or may be defined in different classes as long as those classes have a superclass-subclass relationship.

3.2.5.4 Discussion and sample code

Three concepts

In an earlier module, I explained that most books on OOP will tell you that in order to understand OOP, you must understand the following three concepts:

- Encapsulation
- Inheritance
- Polymorphism

I agree with that assessment.

Encapsulation and inheritance

Previous modules in this series have explained Encapsulation and Inheritance. This module will tackle the somewhat more complex topic of Polymorphism.

Overloading and overriding methods

In the modules on inheritance, you learned a little about overloading and overriding methods (*you will learn more about these concepts as you progress through these modules*) . This module concentrates on the use of overloaded methods to achieve *compile-time polymorphism*.

Real-world scenarios

The sample programs that I used in the previous modules in this series dealt with two kinds of car radios:

- Plain car radios
- Car radios having built-in tape players

I couched those programs in a real-world scenario in an attempt to convince you that encapsulation and inheritance really do have a place in the real world.

Programs were fairly long

However, even though those programs were simple in concept, they were relatively long. That made them somewhat difficult to explain due simply to the amount of code involved.

Keep it short and simple

Beginning with this module, I am going to back away from real-world scenarios and begin using sample programs that are as short and as simple as I know how to make them, while still illustrating the important points under discussion.

My objective in this and future modules is to make the polymorphic concepts as clear as possible without having those concepts clouded by other programming issues.

I will simply ask you to trust me when I tell you that polymorphism has enormous applicability in the real world.

A little more on inheritance

There is another aspect of inheritance that I didn't explain in the previous modules.

Every class extends some other class

Every class in Java extends some other class. If you don't explicitly specify the class that your new class extends, it will automatically extend the class named **Object** .

A class hierarchy

Thus, all classes in Java exist in a class hierarchy where the class named **Object** forms the root of the hierarchy.

Some classes extend **Object** directly, while other classes are subclasses of **Object** further down the hierarchy.

Methods in the Object class

The class named **Object** defines default versions of the following methods:

- clone()
- equals(Object obj)
- finalize()
- getClass()
- hashCode()
- notify()
- notifyAll()
- toString()
- **wait()**
- **wait(long timeout)**
- **wait(long timeout, int nanos)**

As you can see, this list includes three overloaded versions of the method named **wait** . The three versions have the same name but different formal argument lists. Thus, these three methods are *overloaded* versions of the method name **wait** .

Every class inherits these eleven methods

Because every class is either a direct or indirect subclass of **Object** , every class in Java, (*including new classes that you define*) , inherit these eleven methods.

To be overridden ...

Some of these eleven methods are intended to be overridden for various purposes. However, some of them, such as **getClass** , **notify** , and the three versions of **wait** , are intended to be used directly without overriding. (*Although not shown here, these five methods are declared to be **final** , meaning that they may not be overridden.*)

What is polymorphism?

The meaning of the word polymorphism is something like *one name, many forms*.

How does Java implement polymorphism?

Polymorphism manifests itself in Java in the form of multiple methods having the same name.

In some cases, multiple methods have the same name, but different formal argument lists (*overloaded methods*) . In other cases, multiple methods have the same name, same return type, and same formal argument list (*overridden methods*) .

Three distinct forms of polymorphism

From a practical programming viewpoint, polymorphism manifests itself in three distinct forms in Java:

- Method overloading
- Method overriding through inheritance
- Method overriding through the Java interface

Method overloading

I will begin the discussion of polymorphism with method overloading, which is the simplest of the three. I will cover method overloading in this module and will cover polymorphism based on overridden methods and interfaces in subsequent modules.

Method overloading versus method overriding

Don't confuse method *overloading* with method *overriding* .

Java allows you to have two or more method definitions in the same scope with the same name, provided that they have different formal argument lists.

More specifically, here is what Roberts, Heller, and Ernest have to say about overloading methods in their excellent book titled **The Complete Java 2 Certification Study Guide** :

"A valid overload differs in the number or type of its arguments. Differences in argument names are not significant. A different return type is permitted, but is not sufficient by itself to distinguish an overloading method."

Similarly, as a preview of things to come, here is what they have to say about method overriding:

"A valid override has identical argument types and order, identical return type, and is not less accessible than the original method. The overriding method must not throw any checked exceptions that were not declared for the original method."

You should read these two descriptions carefully and make certain that you recognize the differences.

Compile-time polymorphism

Some authors refer to method overloading as a form of *compile-time polymorphism* , as distinguished from *run-time polymorphism* .

This distinction comes from the fact that, with overloaded methods, for each method call, the compiler determines which method (*from a group of overloaded methods*) will be executed, and this decision is made when the program is compiled. (*In contrast, I will tell you later that the determination of which overridden method to execute isn't made until runtime.*)

Selection based on the argument list

In practice, the compiler simply examines the types, number, and order of the parameters being passed in an overloaded method call, and selects the overloaded method having a matching formal argument list.

A sample program

I will discuss a sample program named **Poly01** to illustrate method overloading. A complete listing of the program can be viewed in Listing 4 (p. 347) near the end of the module.

Within the class and the hierarchy

Method overloading can occur both within a class definition, and vertically within the class inheritance hierarchy. (*In other words, an overloaded method can be inherited into a class that defines other overloaded versions of the method.*) The program named **Poly01** illustrates both aspects of method overloading.

Class B extends class A, which extends Object

Upon examination of the program, you will see that the class named **A** extends the class named **Object** . You will also see that the class named **B** extends the class named **A** .

The class named **Poly01** is a driver class whose **main** method exercises the methods defined in the classes named **A** and **B** .

Once again, this program is not intended to correspond to any particular real-world scenario. Rather, it is a very simple program designed specifically to illustrate method overloading.

Will discuss in fragments

As is my usual approach, I will discuss this program in fragments. The code in Listing 1 (p. 343) defines the class named **A** , which explicitly extends **Object** .

Listing 1 . Definition of the class named A.

```
class A extends Object{
public void m(){
    System.out.println("m()");
} //end method m()
} //end class A
```

Table 3.29

Redundant code

Explicitly extending **Object** is not required (*but it also doesn't hurt anything to do it*).

By default, the class named **A** would extend the class named **Object** automatically, unless the class named **A** explicitly extends some other class.

The method named m()

The code in Listing 1 (p. 343) defines a method named **m()**. Note that this version of the method has an empty argument list (*it doesn't receive any parameters when it is executed*). The behavior of the method is simply to display a message indicating that it has been called.

The class named B

Listing 2 (p. 344) contains the definition for the class named **B**. The class named **B** extends the class named **A**, and inherits the method named **m** defined in the class named **A**.

Listing 2 . Definition of the class named B.

```

class B extends A{
public void m(int x){
    System.out.println("m(int x)");
} //end method m(int x)
//-----//

public void m(String y){
    System.out.println("m(String y)");
} //end method m(String y)
} //end class B

```

Table 3.30

Overloaded methods

In addition to the inherited method named **m**, the class named **B** defines two overloaded versions of the method named **m**:

- **m(int x)**
- **m(String y)**

(*Note that each of these two versions of the method receives a single parameter, and the type of the parameter is different in each case.*)

As with the version of the method having the same name defined in the class named **A**, the behavior of each of these two methods is to display a message indicating that it has been called.

The driver class

Listing 3 (p. 345) contains the definition of the driver class named **Poly01**.

Listing 3 . Definition of the driver class named Poly01.

```

public class Poly01{
public static void main(String[] args){
    B var = new B();
    var.m();
    var.m(3);
    var.m("String");
} //end main
} //end class Poly01

```

Table 3.31**Call all three overloaded methods**

The code in the `main` method

- Instantiates a new object of the class named `B` , and
- Successively calls each of the three overloaded versions of the method named `m` on the reference to that object.

One version is inherited

The overloaded version of the method named `m` , defined in the class named `A` , is inherited into the class named `B` . Therefore, it can be called on a reference to an object instantiated from the class named `B` .

Two versions defined in class B

The other two versions of the method named `m` are defined in the class named `B` . Thus, they also can be called on a reference to an object instantiated from the class named `B` .

The output

As you would expect, the output produced by sending messages to the object asking it to execute each of the three overloaded versions of the method named `m` is:

```

m()
m(int x)
m(String y)

```

Note that the values of the parameters passed to the methods do not appear in the output. Rather, in this simple example, the parameters are used solely to make it possible for the compiler to select the correct version of the overloaded method to execute.

This output confirms that each overloaded version of the method is properly selected for execution based on the matching of method parameters to the formal argument list of each method.

3.2.5.5 Summary

Previous modules introduced *overloading* and *overriding* methods. This module concentrates on the use of method *overloading* to achieve *compile-time polymorphism* .

All classes in Java form a hierarchy with a class named `Object` at the root of the hierarchy. Thus, every class in Java is a direct or indirect subclass of the class named `Object` .

If a new class doesn't explicitly extend some other class, it will, by default, automatically extend the class named `Object` .

The `Object` class defines default versions of eleven different methods. These methods are inherited into all other classes, and some (*those not declared `final`*) may be overridden to make their behavior more appropriate for objects instantiated from the new class.

Overloaded methods have the same name and different formal argument lists. They may or may not have the same return type.

Three of the eleven methods defined in the class named **Object** are overloaded versions of the method name **wait** . One version takes no parameters. A second version takes a single parameter of type **long** . The third version takes two parameters, one of type **long** , and one of type **int** .

The word *polymorphism* means something like *one name, many forms* . Polymorphism manifests itself in Java in the form of multiple methods having the same name.

Polymorphism manifests itself in three distinct forms in Java:

- Method overloading
- Method overriding through inheritance
- Method overriding through the Java interface

This module concentrates on method *overloading* , sometimes referred to as *compile-time polymorphism* . This form of polymorphism is distinguished by the fact that the compiler selects a specific method from two or more overloaded methods on the basis of the types and the number of parameters passed to the method when it is called. The selection is made when the program is compiled (*rather than being made later when the program is run*) .

Overloaded methods may all be defined in the same class, or may be defined in different classes as long as those classes have a superclass-subclass relationship in the class hierarchy.

The sample program in this module illustrates three overloaded versions of the same method name with two of the versions being defined in a single class, and the other version being defined in the superclass of that class.

3.2.5.6 What's next?

The next module in this collection teaches you about assignment compatibility, type conversion, and casting for both primitive and reference types.

It also teaches you about the relationship between reference types, method calls, and the location in the class hierarchy where a method is defined.

3.2.6.3 Preview

This module discusses type conversion for both *primitive* and *reference* types.

A value of a particular type may be *assignment compatible* with variables of other types, in which case the value can be assigned directly to the variable. Otherwise, it may be possible to perform a *cast* on the value to change its type and assign it to the variable as the new type.

With regard to reference types, whether or not a cast can be successfully performed

- depends on the relationships of the classes involved in the class hierarchy.

A reference to any object can be assigned to a reference variable of the type `Object`, because the `Object` class is a superclass of every other class.

When we cast a reference along the class hierarchy in a direction from the root class `Object` toward the leaves, we often refer to it as a *downcast*.

Whether or not a method can be called on a reference to an object depends on

- the current type of the reference, and
- the location in the class hierarchy where the method is defined.

In order to use a reference of a class type to call a method, the method must be defined at or above that class in the class hierarchy.

A sample program is provided that illustrates much of the detail involved in type conversion, method calls, and casting with respect to reference types.

3.2.6.4 Discussion and sample code

What is polymorphism?

As a quick review, the meaning of the word *polymorphism* is something like *one name, many forms*.

How does Java implement polymorphism?

Polymorphism manifests itself in Java in the form of multiple methods having the same name.

In some cases, multiple methods have the same name, but different formal argument lists (*overloaded methods, which were discussed in a previous module*).

In other cases, multiple methods have the same name, same return type, and same formal argument list (*overridden methods*).

Three distinct forms of polymorphism

From a practical programming viewpoint, polymorphism manifests itself in three distinct forms in Java:

- Method overloading
- Method overriding through inheritance
- Method overriding through the Java interface

I covered method overloading as one form of polymorphism in a previous module.

We need to backtrack

In this module, I will backtrack a bit and discuss the conversion of references from one type to another.

I will begin the discussion of polymorphism through method overriding and inheritance in the next module. I will cover interfaces in a future module.

Assignment compatibility and type conversion

As a background for polymorphism, you need to understand something about *assignment compatibility* and *type conversion*.

A value of a given type is assignment compatible with another type if

- a value of the first type
- can be successfully assigned to a variable of the second type.

Type conversion and the cast operator

In some cases, type conversion happens automatically. In other cases, type conversion must be forced through the use of a *cast operator* .

A cast operator is a *unary* operator, which has a single right operand. The physical representation of the cast operator is the name of a type inside a pair of matching parentheses, as in:

```
(int)
```

Applying a cast operator

Applying a cast operator to the name of a variable doesn't actually change the type of the variable. However, it does cause the contents of the variable to be treated as a different type for the evaluation of the expression in which the cast operator is contained. Thus, the application of a cast operator is a short-term operation.

Primitive values and type conversion

Assignment compatibility issues come into play for both *primitive* types and *reference* types.

Values of type **boolean** can only be assigned to variables of type **boolean** (*you cannot change the type of a **boolean***) .

Otherwise, a primitive value can be assigned to any variable of a type

- whose range is as wide or wider
- than the range of the type of the value.

In that case, the type of the value is automatically converted to the type of the variable.

(For example, types **byte** and **short** can be assigned to a variable of type **int** without the requirement for a cast because type **int** has a wider range than either type **byte** or type **short** .)

Conversion to narrower range

On the other hand, a primitive value of a given type cannot be assigned to a variable of a type with a narrower range than the type of the value, **unless the cast operator is used to force a type conversion**.

Oftentimes, such a conversion will result in the loss of data, and that loss is the responsibility of the programmer who performs the cast.

Assignment compatibility for references

Assignment compatibility, with respect to references, doesn't involve range issues, as is the case with primitives. Instead, the reference to an object instantiated from a given class can be assigned to:

- **Any reference variable** whose type is the same as the class from which the object was instantiated.
- Any reference variable whose type is a superclass of the class from which the object was instantiated.
- Any reference variable whose type is an interface that is implemented by the class from which the object was instantiated.
- Any reference variable whose type is an interface that is implemented by a superclass of the class from which the object was instantiated, and
- A few other cases involving the class and interface hierarchy.

Such an assignment does not require the use of a cast operator.

Type Object is completely generic

A reference to any object can be assigned to a reference variable of the type **Object** , because the **Object** class is a superclass of every other class.

Converting reference types with a cast

Assignments of references, other than those listed above (p. 350) , require the use of a cast operator to purposely change the type of the reference.

Doesn't work in all cases

However, it is not possible to perform a successful cast to convert the type of a reference in all cases.

Generally, a cast can only be performed among reference types that fall on the same ancestral line of the class hierarchy, or on an ancestral line of an interface hierarchy. For example, a reference cannot be successfully cast to the type of a sibling or a cousin in the class hierarchy.

Downcasting

When we cast a reference along the class hierarchy in a direction from the root class **Object** toward the leaves, we often refer to it as a *downcast*.

While it is also possible to cast in the direction from the leaves to the root, this happens automatically, and the use of a cast operator is not required.

A sample program

The program named **Poly02**, shown in Listing 11 (p. 357) near the end of the module, illustrates the use of the cast operator with references.

When you examine that program, you will see that two classes named **A** and **C** each extend the class named **Object**. Hence, we might say that they are siblings in the class hierarchy.

Another class named **B** extends the class named **A**. Thus, we might say that **A** is a child of **Object**, and **B** is a child of **A**.

The class named A

The definition of the class named **A** is shown in Listing 1 (p. 351). This class extends the class named **Object**.

*(Recall that it is not necessary to explicitly state that a class extends the class named **Object**. Any class that does not explicitly extend some other class will automatically extend **Object** by default. The class named **A** is shown to extend **Object** here simply for clarity of presentation.)*

Listing 1 . Definition of the class named A.

```
class A extends Object{
    //this class is empty
} //end class A
```

Table 3.33

The class named **A** is empty. It was included in this example for the sole purpose of adding a layer of inheritance to the class hierarchy.

The class named B

Listing 2 (p. 351) shows the definition of the class named **B**. This class extends the class named **A**.

Listing 2 . Definition of the class named B.

```
class B extends A{
    public void m(){
        System.out.println("m in class B");
    } //end method m()
} //end class B
```

Table 3.34

The method named m()

The class named **B** defines a method named **m()**. The behavior of the method is simply to display a message each time it is called.

The class named C

Listing 3 (p. 352) contains the definition of the class named **C**, which also extends **Object**.

Listing 3 . Definition of the class named C.

```
class C extends Object{
  //this class is empty
} //end class C
```

Table 3.35

The class named **C** is also empty. It was included in this example as a sibling class for the class named **A**. Stated differently, it was included as a class that is not in the ancestral line of the class named **B**.

The driver class

Listing 4 (p. 352) shows the beginning of the driver class named **Poly02**.

Listing 4 . Beginning of the class named Poly02.

```
public class Poly02{
  public static void main(String[] args){
    Object var = new B();
```

Table 3.36**An object of the class named B**

The code in Listing 4 (p. 352) instantiates an object of the class **B** and assigns the object's reference to a reference variable of type **Object**.

*(It is important to note that the reference to the object of type **B** was not assigned to a reference variable of type **B**. Instead, it was assigned to a reference variable of type **Object**.)*

This assignment is allowable because **Object** is a superclass of **B**. In other words, the reference to the object of the class **B** is assignment compatible with a reference variable of the type **Object**.

Automatic type conversion

In this case, the reference of type **B** is automatically converted to type **Object** and assigned to the reference variable of type **Object**. *(Note that the use of a cast operator was not required in this assignment.)*

Only part of the story

However, assignment compatibility is only part of the story. The simple fact that a reference is assignment compatible with a reference variable of a given type says nothing about what can be done with the reference after it is assigned to the reference variable.

An illegal operation

For example, in this case, the reference variable that was automatically converted to type **Object** cannot be used directly to call the method named **m()** on the object of type **B**. This is indicated in Listing 5 (p. 353).

Listing 5 . An illegal operation.

```
//var.m();
```

Table 3.37

An attempt to call the method named `m()` on the reference variable of type `Object` in Listing 5 (p. 353) resulted in a compiler error. It was necessary to convert the statement into a comment in order to get the program to compile successfully.

An important rule

In order to use a reference of a class type to call a method, the method must be defined at or above that class in the class hierarchy.

This case violates the rule

In this case, the method named `m()` is defined in the class named `B`, which is two levels down from the class named `Object`.

When the reference to the object of the class `B` was assigned to the reference variable of type `Object`, the type of the reference was automatically converted to type `Object`.

Therefore, because the reference is of type `Object`, it cannot be used directly to call the method named `m()`.

The solution is a downcast

In this case, the solution to the problem is a downcast. The code in Listing 6 (p. 353) shows an attempt to solve the problem by casting the reference down the hierarchy to type `A`.

Listing 6 . An ineffective downcast.

```
//((A)var).m();
```

Table 3.38**Still doesn't solve the problem**

However, this still doesn't solve the problem, and the result is another compiler error. Again, it was necessary to convert the statement into a comment in order to get the program to compile.

What is the problem here?

The problem is that the downcast simply didn't go far enough down the inheritance hierarchy.

The class named `A` neither defines nor inherits the method named `m()`. The method named `m()` is defined in class `B`, which is a subclass of class `A`.

Therefore, a reference of type `A` is no more useful than a reference of type `Object` insofar as calling the method named `m()` is concerned.

The real solution

The solution to the problem is shown in Listing 7 (p. 354).

Listing 7 . A downcast to type B.

```
((B)var).m();
```

Table 3.39

The code in Listing 7 (p. 354) casts (*temporarily converts*) the reference value contained in the **Object** variable named **var** down to type **B** .

The method named **m()** is defined in the class named **B** . Therefore, a reference of type **B** can be used to call the method.

The code in Listing 7 (p. 354) compiles and executes successfully. This causes the method named **m()** to execute, producing the following output on the computer screen.

```
m in class B
```

A few odds and ends

Before leaving this topic, let's look at a couple more issues. The code in Listing 8 (p. 354) declares and populates a new variable of type **B** .

Listing 8 . Declare a variable of type B.

```
B v1 = (B)var;
```

Table 3.40

The code in Listing 8 (p. 354) also uses a cast to:

- Convert the contents of the **Object** variable to type **B**
- **Assign the converted reference to the new reference variable of type B.**

A legal operation

This is a legal operation. In this class hierarchy, the reference to the object of the class **B** can be assigned to a reference variable of the types **B** , **A** , or **Object** .

Cannot be assigned to type C

However, the reference to the object of the class **B** cannot be assigned to a reference variable of any other type, including the type **C** . An attempt to do so is shown in Listing 9 (p. 354) .

Listing 9 . Cannot be assigned to type C.

```
//C v2 = (C)var;
```

Table 3.41

The code in Listing 9 (p. 354) attempts to cast the reference to type `C` and assign it to a reference variable of type `C`.

A runtime error

Although the program will compile, it won't execute. An attempt to execute the statement in Listing 9 (p. 354) results in a `ClassCastException` at runtime. As a result, it was necessary to convert the statement into a comment in order to execute the program.

Another failed attempt

Similarly, an attempt to cast the reference to type `B` and assign it to a reference variable of type `C`, as shown in Listing 10 (p. 355), won't compile.

Listing 10 . Another failed attempt.
<pre>//C v3 = (B)var;</pre>

Table 3.42

The problem here is that the class `C` is not a superclass of the class named `B`. Therefore, a reference of type `B` is not assignment compatible with a reference variable of type `C`.

Again, it was necessary to convert the statement into a comment in order to compile the program.

3.2.6.5 Summary

This module discusses type conversion for both primitive and reference types.

A value of a particular type may be assignment compatible with variables of other types.

If the type of a value is not assignment compatible with a variable of a given type, it may be possible to perform a cast on the value to change its type and assign it to the variable as the new type. For primitive types, this will often result in the loss of information.

Except for type `boolean`, values of primitive types can be assigned to any variable whose type represents a range that is as wide or wider than the range of the value's type. (*Values of type `boolean` can only be assigned to variables of type `boolean`.*)

With respect to reference types, the reference to an object instantiated from a given class can be assigned to any of the following without the use of a cast:

- Any reference variable whose type is the same as the class from which the object was instantiated.
- Any reference variable whose type is a superclass of the class from which the object was instantiated.
- Any reference variable whose type is an interface that is implemented by the class from which the object was instantiated.
- Any reference variable whose type is an interface that is implemented by a superclass of the class from which the object was instantiated.
- A few other cases involving the class and interface hierarchy.

Assignments of references, other than those listed above, require the use of a cast to change the type of the reference.

It is not always possible to perform a successful cast to convert the type of a reference. Whether or not a cast can be successfully performed depends on the relationship of the classes involved in the class hierarchy.

A reference to any object can be assigned to a reference variable of the type `Object`, because the `Object` class is a superclass of every other class.

When we cast a reference along the class hierarchy in a direction from the root class `Object` toward the leaves, we often refer to it as a *downcast*.

Whether or not a method can be called on a reference to an object depends on the current type of the reference and the location in the class hierarchy where the method is defined. In order to use a reference of a class type to call a method, the method must be defined at or above that class in the class hierarchy.

A sample program is provided that illustrates much of the detail involved in type conversion, method invocation, and casting with respect to reference types.

3.2.6.6 What's next?

I will begin the discussion of runtime polymorphism through method overriding and inheritance in the next module.

I will demonstrate that for runtime polymorphism, the selection of a method for execution is based on the actual type of object whose reference is stored in a reference variable, and not on the type of the reference variable on which the method is called.

What is polymorphism?

The meaning of the word *polymorphism* is something like *one name, many forms* .

How does Java implement polymorphism?

Polymorphism manifests itself in Java in the form of multiple methods having the same name.

In some cases, multiple methods have the same name, but different formal argument lists (*overloaded methods, which were discussed in a previous module*) .

¹¹²This content is available online at <<http://cnx.org/content/m44177/1.5/>>.

¹¹³<http://cnx.org/contents/dzOvxPFw>

¹¹⁴http://cnx.org/contents/-2RmHFs_

In other cases, multiple methods have the same name, same return type, and same formal argument list (*overridden methods*) .

Three distinct forms of polymorphism

From a practical programming viewpoint, polymorphism manifests itself in three distinct forms in Java:

- Method overloading
- Method overriding through class inheritance
- Method overriding through the Java interface

I covered method overloading as one form of polymorphism (*compile-time polymorphism*) in a previous module. I also explained automatic type conversion and the use of the cast operator for type conversion in a previous module.

In this module ...

I will begin the discussion of runtime polymorphism through method overriding and class inheritance in this module. I will cover interfaces in a future module.

The essence of runtime polymorphic behavior

With runtime polymorphism based on method overriding,

- the decision as to which version of a method will be executed is based on
- the actual type of the object whose reference is stored in the reference variable, and
- **not** on the type of the reference variable on which the method is called.

Late binding

The decision as to which version of the method to call cannot be made at compile time. That decision must be deferred and made at runtime. This is sometimes referred to as *late binding* .

3.2.7.4 Discussion and sample code

Operational description of runtime polymorphism

Here is an operational description of runtime polymorphism as implemented in Java through class inheritance and method overriding:

- Assume that a class named **SuperClass** defines a method named **method** .
- Assume that a class named **SubClass** extends **SuperClass** and overrides the method named **method** .
- Assume that a reference to an object of the class named **SubClass** is assigned to a reference variable named **ref** of type **SuperClass** .
- Assume that the method named **method** is then called on the reference variable using the following syntax:
 - **ref.method()**
- **Result:** The version of the method named **method** that will actually be executed is the *overridden* version in the class named **SubClass** , and is not the version that is defined in the class named **SuperClass**, even though the reference to the object of type **SubClass** is stored in a variable of type **SuperClass** .

This is runtime polymorphism in a nutshell, which is sometimes also referred to as late-binding.

Runtime polymorphism is very powerful

As you gain more experience with Java, you will learn that much of the power of OOP using Java is centered on runtime polymorphism using class inheritance, interfaces, and method overriding. (*The use of interfaces for polymorphism will be discussed in a future module.*)

An important attribute of runtime polymorphism

The decision as to which version of the method to execute

- is based on the actual type of object whose reference is stored in the reference variable, and
- is not based on the type of the reference variable on which the method is called.

Why is it called runtime polymorphism?

The reason that this type of polymorphism is often referred to as *runtime polymorphism* is because the decision as to which version of the method to execute cannot be made until runtime. The decision cannot be made at compile time.

Why defer the decision?

The decision cannot be made at compile time because the compiler has no way of knowing (*when the program is compiled*) the actual type of the object whose reference will be stored in the reference variable .

In an extreme case, for example, the object might be de-serialized at runtime from a network connection of which the compiler has no knowledge.

Could be either type

For the situation described above, that de-serialized object could just as easily be of type **SuperClass** as of type **SubClass** . In either case, it would be valid to assign the object's reference to the same superclass reference variable.

If the object were of the **SuperClass** type, then a call to the method named **method** on the reference would cause the version of the method defined in **SuperClass** , and not the version defined in **SubClass** , to be executed. (*The version executed is determined by the type of the object and not by the type of the reference variable containing the reference to the object.*)

Sample Program

Let's take a look at a sample program that illustrates runtime polymorphism using class inheritance and overridden methods. The name of the program is **Poly03** . A complete listing of the program is shown in Listing 7 (p. 366) near the end of the module.

Listing 1 (p. 360) shows the definition of a class named **A** , which extends the class named **Object** .

(*Remember that any class that doesn't extend some other class automatically extends **Object** by default, and it is not necessary to show that explicitly as I did in this example.*)

Listing 1 . Definition of the class named A.

```
class A extends Object{
public void m(){
    System.out.println("m in class A");
} //end method m()
} //end class A
```

Table 3.44

The class named **A** defines a method named **m()** .

Behavior of the method

The behavior of the method, as defined in the class named **A** , is to display a message indicating that it has been called, and that it is defined in the class named **A** .

This message will allow us to determine which version of the method is executed in each case discussed later.

The class named B

Listing 2 (p. 361) shows the definition of a class named **B** that extends the class named **A** .

Listing 2 . Definition of the class named B.

```

class B extends A{
public void m(){
    System.out.println("m in class B");
} //end method m()
} //end class B

```

Table 3.45

The class named **B** overrides (*redefines*) the method named **m()** , which it inherits from the class named **A** .

Behavior of the overridden version of the method

Like the inherited version, the overridden version displays a message indicating that it has been called. However, the message is different from the message displayed by the inherited version discussed above. The overridden version tells us that it is defined in the class named **B** . (*The behavior of the overridden version of the method is appropriate for an object instantiated from the class named B .*)

Again, this message will allow us to determine which version of the method is executed in each case discussed later.

The driver class

Listing 3 (p. 361) shows the beginning of the driver class named **Poly03** .

Listing 3 . Beginning of the driver class named Poly03.

```

public class Poly03{
public static void main(String[] args){
    Object var = new B();
    ((B)var).m();
}
}

```

Table 3.46**A new object of the class B**

The code in the **main** method begins by instantiating a new object of the class named **B** , and assigning the object's reference to a reference variable of type **Object** .

(*Recall that this is legal because an object's reference can be assigned to any reference variable whose type is a superclass of the class from which the object was instantiated. The class named **Object** is the superclass of all classes.*)

Downcast and call the method

If you read the earlier module on casting, it will come as no surprise to you that the second statement in the **main** method, which casts the reference down to type **B** and calls the method named **m()** on it, will compile and execute successfully.

Which version is executed?

The execution of the method produces the following output on the computer screen:

```
m in class B
```

By examining the output, you can confirm that the version of the method that was overridden in the class named **B** is the version that was executed.

Why was this version executed?

This should also come as no surprise to you. The cast converts the type of the reference from type **Object** to type **B**.

You can always call a public method belonging to an object using a reference to the object whose type is the same as the class from which the object was instantiated.

Not runtime polymorphic behavior

Just for the record, the above call to the method does not constitute runtime polymorphism (*in my opinion*). I included that call to the method to serve as a backdrop for what follows.

Runtime polymorphic behavior

However, the following call to the method does constitute runtime polymorphism.

The statement in Listing 4 (p. 362) casts the reference down to type **A** and calls the method named **m()** on that reference.

It may not come as a surprise to you that the call to the method shown in Listing 4 (p. 362) also compiles and runs successfully.

Listing 4 . Polymorphic behavior.
<pre>((A)var).m();</pre>

Table 3.47

The method output

Here is the punch line. Not only does the statement in Listing 4 (p. 362) compile and run successfully, it produces the following output, (*which is exactly the same output as before*):

```
m in class B
```

Same method executed in both cases

It is important to note that this output, (*produced by casting the reference variable to type **A** instead of type **B***), is exactly the same as that produced by the earlier call to the method when the reference was cast to type **B**. This means that the same version of the method was executed in both cases.

This confirms that, even though the type of the reference was converted to type **A**, (*rather than type **Object** or type **B***), the overridden version of the method defined in class **B** was actually executed.

This is an example of runtime polymorphic behavior.

The version of the method that was executed was based on

- the actual type of the object, **B**, and
- not on the type of the reference, **A**.

This is an extremely powerful and useful concept.

Another call to the method

Now take a look at the statement in Listing 5 (p. 363). Will this statement compile and execute successfully? If so, which version of the method will be executed?

Listing 5 . Source of a compiler error.

```
var.m();
```

Table 3.48**Compiler error**

The code in Listing 5 (p. 363) attempts, unsuccessfully, to call the method named `m()` using the reference variable named `var`, which is of type `Object`. The result is a compiler error, which, depending on your version of the JDK, will be similar to the following:

```
Poly03.java:40: cannot resolve symbol
symbol   : method m ()
location: class java.lang.Object
    var.m();
        ^
```

Some important rules

The `Object` class does not define a method named `m()`. Therefore, the overridden method named `m()` in the class named `B` is not an overridden version of a method that is defined in the class named `Object`.

Necessary, but not sufficient

Runtime polymorphism based on class inheritance requires that the type of the reference variable be a superclass of the class from which the object (*on which the method will be called*) is instantiated.

However, while necessary, that is not sufficient.

The type of the reference variable must also be a class that either *defines or inherits* the method that will ultimately be called on the object.

This method is not defined in the Object class

Since the class named `Object` neither defines nor inherits the method named `m()`, a reference of type `Object` does not qualify as a participant in runtime polymorphic behavior in this case. The attempt to use it as a participant resulted in the compiler error given above.

One additional scenario

Before leaving this topic, let's look at one additional scenario to help you distinguish what is, and what is not, runtime polymorphism. Consider the code shown in Listing 6 (p. 363).

Listing 6 . A new object of type A.

```
var = new A();
((A)var).m();
```

Table 3.49**A new object of type A**

The code in Listing 6 (p. 363) instantiates a new object of the class named `A`, and stores the object's reference in the original reference variable named `var` of type `Object`.

(As a side note, this overwrites the previous contents of the reference variable with a new reference and causes the object whose reference was previously stored there to become eligible for garbage collection.)

Downcast and call the method

Then the code in Listing 6 (p. 363) casts the reference down to type **A** , (*the type of the object to which the reference refers*) , and calls the method named **m()** on the downcast reference.

The output

As you would probably predict, this produces the following output on the computer screen:

```
m in class A
```

In this case, the version of the method defined in the class named **A** , (*not the version defined in **B***) was executed.

Not polymorphic behavior

In my view, this is not polymorphic behavior (*at least it isn't a very useful form of polymorphic behavior*) . This code simply converts the type of the reference from type **Object** to the type of the class from which the object was instantiated, and calls one of its methods. Nothing special takes place regarding a selection among different versions of the method.

Some authors may disagree

While some authors might argue that this is technically runtime polymorphic behavior, in my view at least, it does not illustrate the real benefits of runtime polymorphic behavior. The benefits of runtime polymorphic behavior generally accrue when the actual type of the object is a subclass of the type of the reference variable containing the reference to the object.

Once again, what is runtime polymorphism?

As I have discussed in this module, runtime polymorphic behavior based on class inheritance occurs when

- The type of the reference is a superclass of the class from which the object was instantiated.
- The version of the method that is executed is the version that is either defined in, or inherited into, the class from which the object was instantiated.

More than you ever wanted to hear

And that is probably more than you ever wanted to hear about runtime polymorphism based on class inheritance.

A future module will discuss runtime polymorphism based on the Java interface. From a practical viewpoint, you will find the rules to be similar but somewhat different in the case of the Java interface.

A very important concept

As an example of the importance of runtime polymorphism in Java, the entire event-driven graphical user interface structure of Java is based on runtime polymorphism involving the Java interface.

3.2.7.5 Summary

Polymorphism manifests itself in Java in the form of multiple methods having the same name.

From a practical programming viewpoint, polymorphism manifests itself in three distinct forms in Java:

- Method overloading
- Method overriding through class inheritance
- Method overriding through the Java interface

This module discusses method overriding through class inheritance.

With runtime polymorphism based on method overriding, the decision as to which version of a method will be executed is based on the actual type of object whose reference is stored in the reference variable, and not on the type of the reference variable on which the method is called.

The decision as to which version of the method to call cannot be made at compile time. That decision must be deferred and made at runtime. This is sometimes referred to as late binding.

This is illustrated in the sample program discussed in this module.

3.2.7.6 What's next?

In the next module, I will continue my discussion of the implementation of polymorphism using method overriding through class inheritance, and I will concentrate on a special case in that category.

Specifically, I will discuss the use of the **Object** class as a completely generic type for storing references to objects of subclass types, and explain how that results in a very useful form of runtime polymorphism.

What is polymorphism?

If you have studied the earlier modules in this collection, you should already know what polymorphism is, how it is implemented in Java, the three distinct forms of polymorphism in Java, etc.

I discussed runtime polymorphism implemented through method overriding and class inheritance in a previous module. However, before leaving that topic, I need to discuss an important special case.

¹¹⁵This content is available online at <<http://cnx.org/content/m44190/1.7/>>.

¹¹⁶<http://cnx.org/contents/dzOvxPFw>

¹¹⁷http://cnx.org/contents/-2RmHF_s_

In this module, I will discuss the use of the **Object** class as a completely generic type for storing references to objects of subclass types, and will explain how that results in a very useful form of runtime polymorphism.

I will briefly discuss the default versions of eleven methods defined in the **Object** class, and will explain that in many cases, those default versions are meant to be overridden.

3.2.8.4 Discussion and sample code

The Java Collections Framework

Java supports a framework, known as the Java Collections Framework, which you can read about here ¹¹⁸.

Without getting into a lot of detail, the framework provides several concrete implementations of interfaces with names like **list**, **set**, and **map**.

The classes that provide the implementations have names like **LinkedList**, **TreeSet**, **ArrayList**, **Vector**, and **Hashtable**. As you might recognize, the framework satisfies the requirements for what we might refer to as classical data structures.

Not the purpose ...

However, it is not the purpose of this module to discuss either the Java Collections Framework, or classical data structures. Rather, they are mentioned here simply because the framework provides a good example of the use of the **Object** class as a generic type for runtime polymorphic behavior.

(Also beyond the scope of this module is the fact that the framework provides an outstanding example of the implementation of polymorphic behavior through the use of the Java interface. The use of the Java interface is a topic for a future module)

References of type Object

The classes mentioned above store references to objects created according to interfaces, contracts, and stipulations provided by the framework. More importantly for the purposes of this module, those references are stored as type **Object**. (See *Java4210: Getting Started with Generics* ¹¹⁹ for additional information on this topic.)

The **Object** type is a completely generic type, which can be used to store a reference to any object that can be instantiated in Java.

Methods defined in the Object class

In an earlier module, I told you that the class named **Object** defines default versions of the following methods:

- clone()
- equals(Object obj)
- finalize()
- getClass()
- hashCode()
- notify()
- notifyAll()
- toString()
- wait()
- wait(long timeout)
- wait(long timeout, int nanos)

Every class inherits these methods

Because every class is either a direct or indirect subclass of **Object**, every class in Java, (*including new classes that you define*), inherits these eleven methods.

To be overridden ...

¹¹⁸<http://cnx.org/contents/dzOvxPFw:BaPSYl18>

¹¹⁹http://cnx.org/contents/-2RmHFs_:Ss0r2-1m

Some of these eleven methods are intended to be overridden for various purposes.

Calling methods of the **Object** class

You can store a reference to any object in a reference variable of type **Object** .

If you have studied the previous modules in this collection, you also know how runtime polymorphism based on class inheritance works.

Given the above, you should know that you can call any of the methods defined in the **Object** class on any reference to any object stored in a reference variable of type **Object** (*including the references stored in the concrete implementations of the Java Collections Framework*) .

And the behavior will be ...

If the class from which that object is instantiated inherits or defines an overridden version of one of the methods in the above list, calling that method on the reference will cause the overridden version to be executed.

Otherwise, calling that method on the reference will cause the default version defined in the **Object** class to be executed.

A sample program

This is illustrated in the program named **Poly04** , which you can view in its entirety in Listing 7 (p. 375) near the end of this module.

For purposes of illustration, this program deals specifically with the method named **toString** from the above list, but it could deal just as well with other non-final methods in the list.

The class named **A**

Listing 1 (p. 369) defines a class named **A** , which extends the class named **Object** (*recall that it is not necessary to explicitly show that a class extends **Object***).

Listing 1 . Definition of the class named **A**.

```
class A extends Object{
    //This class is empty
} //end class A
```

Table 3.51

Does not override the **toString** method

The most important thing to note about the class named **A** is that it does not override any of the methods that it inherits from the class named **Object** .

For purposes of this illustration, we will say that it inherits the default version of the method named **toString** , from the class named **Object** . (*We will see an example of the behavior of the default version of the **toString** method shortly.*)

The class named **B**

Listing 2 (p. 369) contains the definition of a class named **B** . This class extends the class named **A** .

Listing 2 . Definition of the class named **B**.

continued on next page

```

class B extends A{
public String toString(){
    return "toString in class B";
} //end overridden toString()
} //end class B

```

Table 3.52

Overrides the `toString` method

Of particular interest, for purposes of this module, is the fact that the class named **B** does override the inherited `toString` method.

*(The class named **B** inherits the default version of the method, because its superclass named **A**, which extends **Object**, does not override the `toString` method.)*

Purpose of the `toString` method

The purpose of the `toString` method is to return a reference to an object of the class **String** that represents an object instantiated from a class that overrides the method.

Here is part of what Sun has to say about the `toString` method:

"Returns a string representation of the object. In general, the `toString` method returns a string that textually represents" this object. The result should be a concise but informative representation that is easy for a person to read. It is recommended that all subclasses override this method."

Behavior of the overridden version

As you can see, I didn't follow Sun's advice very closely in this program. To begin with, I didn't override the `toString` method in the class named **A**.

Further, the behavior of my overridden version of the `toString` method in the class named **B** doesn't provide much in the way of a textual representation of an object instantiated from class **B**.

My overridden version simply returns a reference to a **String** object, containing text that indicates that the overridden version of the method defined in the class named **B** has been executed. *(Of course, there wasn't much about an object instantiated from the class named **B** that could be represented in a textual way.)*

Will be useful later

The reference to the **String** object returned by the overridden version of the `toString` method will prove useful later when we need to determine which version of the method is actually executed.

The class named **C**

Listing 3 (p. 370) shows the definition of a class named **C**, which extends the class named **B**, and overrides the method named `toString` again. *(A non-final method can be overridden by every class that inherits it, resulting in potentially many different overridden versions of a method in a class hierarchy.)*

Listing 3 . Definition of the class named **C**.

```

class C extends B{
public String toString(){
    return "toString in class C";
} //end overridden toString()
} //end class C

```

Table 3.53

Behavior of overridden version

The behavior of this overridden version of the method is similar to, but different from the overridden version in the class **B** .

In this case, the method returns a reference to a **String** object that can be used to confirm that this overridden version of the method has been executed.

The driver class

Finally, Listing 4 (p. 371) shows the beginning of the driver class named **Poly04** .

Listing 4 . Beginning of the class named Poly04.

```
public class Poly04{
public static void main(String[] args){
    Object varA = new A();
    String v1 = varA.toString();
    System.out.println(v1);
}
```

Table 3.54**A new object of the class A**

The **main** method of the driver class begins by instantiating a new object of the class **A** , and saving the object's reference in a reference variable of type **Object** , named **varA** .

Call toString method on the reference

Then the code in Listing 4 (p. 371) calls the **toString** method on the reference variable named **varA** , saving the returned reference to the **String** in a reference variable of type **String** named **v1** .

Display the returned String

Finally, that reference is passed to the **println** method, causing the **String** returned by the **toString** method to be displayed on the computer screen.

(In a future module, you will learn that some of the code in Listing 4 (p. 371) (p. 371) is redundant.)

This causes the following text to be displayed on the computer screen:

```
A@111f71
```

Pretty ugly, huh?

Nowhere does our program explicitly show the creation of any text that looks anything like this. Where did it come from?

Default toString behavior

What you are seeing here is the **String** produced by the default version of the **toString** method, as defined by the class named **Object** .

Class A does not override toString

Recall that our new class named **A** does not override the **toString** method. Therefore, when the **toString** method is called on a reference to an object of the class **A** , the default version of the method is executed, producing output similar to that shown above (p. 371) .

What does Sun have to say?

Here is more of what Sun has to say about the default version of the **toString** method

*"The **toString** method for class **Object** returns a string consisting of the name of the class of which the object is an instance, the at-sign character '@', and the unsigned hexadecimal representation of the hash code of the object."*

You should recognize this as a description of the output produced by calling the **toString** method on the reference to the object of the class **A** . That explains the ugliness of the screen output shown above (p. 371) (*hexadecimal representations of hashcodes are usually pretty ugly*) .

A new object of the class B

Now consider the code shown in Listing 5 (p. 372) , which instantiates a new object of the class named **B** , and stores the object's reference in a reference variable of type **Object** .

Listing 5 . A new object of the class named B.

```
Object varB = new B();
String v2 = varB.toString();
System.out.println(v2);
```

Table 3.55

Call toString and display the result

The code in Listing 5 (p. 372) calls the **toString** method on the reference of type **Object** , saving the returned reference in the reference variable named **v2** . (Recall that the **toString** method is overridden in the class named B.)

As before, the reference is passed to the **println** method, which causes the following text to be displayed on the computer screen.

```
toString in class B
```

Do you recognize this?

You should recognize this as the text that was encapsulated in the **String** object by the overridden version of the **toString** method defined in the class named **B** .

Overridden version of toString was executed

This verifies that even though the reference to the object of the class **B** was stored in a reference variable of type **Object** , the overridden version of the **toString** method defined in the class named **B** was executed (instead of the default version defined in the class named **Object**) . This is a good example of *runtime polymorphic behavior* , as described in a previous module.

As you learned in the previous module, the selection of a method for execution is based on the *actual type of object* whose reference is stored in a reference variable, and **not** on the *type of the reference variable* on which the method is called.

An object of the class C

Finally, the code in Listing 6 (p. 372)

- Instantiates a new object of the class **C** .
- Stores the object's reference in a reference variable of type **Object** .
- Calls the **toString** method on the reference.
- Displays the returned string on the computer screen.

Listing 6 . A new object of the class named C.

```
Object varC = new C();
String v3 = varC.toString();
System.out.println(v3);
```

Table 3.56

What will the output look like?

By now, you should know what to expect in the way of text appearing on the computer screen. The code in Listing 6 (p. 372) causes the following text to be displayed:

```
toString in class C
```

Overridden version of toString was called

This confirms what you should already have known by now. In particular, even though the reference to the object of the class `C` is stored in a reference variable of type `Object`, the overridden version of the `toString` method defined in the class named `C` was executed. Again, this is *runtime polymorphic behavior* based on class inheritance and method overriding.

No downcasting was required

It is also very important to note that no downcasting was required in order to call the `toString` method in any of the cases shown above.

Because a default version of the `toString` method is defined in the `Object` class, the `toString` method can be called without a requirement for downcasting on a reference to any object stored in a variable of type `Object`. This holds true for any of the eleven methods defined in the class named `Object` (*although some of those methods are declared `final` and therefore may not be overridden*).

3.2.8.5 Summary

Polymorphism manifests itself in Java in the form of multiple methods having the same name.

From a practical programming viewpoint, polymorphism manifests itself in three distinct forms in Java:

- Method overloading
- Method overriding through class inheritance
- Method overriding through the Java interface

In this module, I have continued my discussion of the implementation of polymorphism using method overriding through class inheritance, and have concentrated on a special case in that category.

More specifically, in this module, I have discussed the use of the `Object` class as a completely generic type for storing references to objects of subclass types, and have explained how that results in a very useful form of runtime polymorphism.

I briefly mentioned the default version of the eleven methods defined in the `Object` class, and explained that in some cases, those default versions are meant to be overridden.

I provided a sample program that illustrates the overriding of the `toString` method, which is one of the eleven methods defined in the `Object` class.

3.2.8.6 What's next?

In the next module, I will embark on an explanation of runtime polymorphic behavior based on the Java interface and method overriding.

In my opinion, this is one of the most important concepts in Java OOP, and the one that seems to give students the greatest amount of difficulty.

3.2.9.3 Preview

Method overloading

I covered method overloading as one form of polymorphism (*compile-time polymorphism*) in a previous module. I also explained automatic type conversion and the use of the cast operator for type conversion in a previous module.

Method overriding and class inheritance

I also discussed runtime polymorphism implemented through method overriding and class inheritance in previous modules.

Using the Java interface

In this module and the next, I will explain runtime polymorphism as implemented using method overriding and the Java interface.

A very important concept

In my opinion, this is one of the most important concepts in Java OOP, and the one that seems to give students the greatest amount of difficulty. Therefore, I will try to take it slow and easy. As usual, I will illustrate the concept using sample programs.

I will also tie this concept back to the concept of polymorphism using method overriding through inheritance.

A skeleton program

In this module, I will present a simple skeleton program that illustrates many of the important aspects of polymorphic behavior based on the Java interface.

Multiple inheritance and the cardinal rule

I will explain how the implementation of interfaces in Java is similar to multiple inheritance. I will explain the cardinal rule of interface implementation.

A new relationship

I will explain that objects instantiated from classes that implement the same interface have a new relationship that goes beyond the relationship imposed by the standard class hierarchy.

One object, many types

I will explain that due to the combination of the class hierarchy and the fact that a class can implement many different interfaces, a single object in Java can be treated as many different types. However, for any given type, there are restrictions on the methods that can be called on the object.

Many classes, one type

I will explain that because different classes can implement the same interface, objects instantiated from different classes can be treated as a common interface type.

Interfaces are critical to Java programming

I will suggest that there is little if anything useful that can be done in Java without understanding and using interfaces.

In support of this suggestion, I will discuss several real-world examples of the use of the Java interface, including the Delegation Event Model, the Model View Control paradigm, and iterators in Java data structures.

3.2.9.4 Discussion and sample code

Listing 6 (p. 386) near the end of the module contains a very simple program named **Poly05** .

The purpose of this program is to illustrate polymorphic behavior using interfaces in addition to class inheritance.

Designed to illustrate structure

This is a skeleton program designed solely to illustrate the inheritance and interface implementation structure in as simple a program as possible. (*I will put some meat on this skeleton using another program in the next module.*)

Empty methods

Except for the two methods that return type **String** , all of the methods in the program are empty. (Methods that return type **String** cannot be empty. They must contain a **return** statement in order to compile successfully.)

Interface definitions

Listing 1 (p. 378) shows the definition of two simple interfaces named **I1** and **I2** .

Listing 1 . Definition of interfaces named I1 and I2.

```
interface I1{
    public void p();
} //end interface I1

//=====//

interface I2 extends I1{
    public void q();
} //end interface I2
```

Table 3.58

Similar but different

An interface definition is similar to a class definition. However, there are some very important differences.

No single hierarchy

To begin with, unlike the case with classes, there is no single interface hierarchy. Also, multiple inheritance is allowed when extending interfaces.

A new interface can extend none, one, or more existing interfaces. In Listing 1 (p. 378) , **I2** extends **I1** , but **I1** doesn't extend any other interface (and unlike classes, an interface doesn't automatically extend another interface by default) .

Two kinds of members allowed

Only two kinds of members are allowed in an interface definition:

- Methods, which are implicitly abstract
- Variables, which are implicitly constant (*final*)

Each of the interfaces in Listing 1 (p. 378) declares an implicitly abstract method (an abstract method does not have a body) .

Neither of the interfaces in Listing 1 (p. 378) declares any variables (they aren't needed for the purpose of this module) .

A new data type

I told you earlier that when you define a new class, you cause a new data type to become available to your program. The same is true of an interface definition. Each interface definition constitutes a new type.

The class named A

Listing 2 (p. 379) defines a very simple class named **A** , which in turn defines two methods named **toString** and **x** .

Listing 2 . Definition of the class named A.

```

class A extends Object{
public String toString(){
    return "toString in A";
} //end toString()
//-----//

public String x(){
    return "x in A";
} //end x()
//-----//
} //end class A

```

Table 3.59**Overridden toString**

The method named **toString** in Listing 2 (p. 379) is actually an overridden version of the method having the same name that is defined in the class named **Object** . (Recall that a previous module made heavy use of overridden versions of the **toString** method.)

New method

The method named **x** is newly defined in the class named **A** . (The method named **x** is not inherited into the class named **A** , because the class named **Object** does not define a method named **x** .)

The class named B

Listing 3 (p. 379) contains material that is new to this module.

Listing 3 . Definition of the class named B.

```

class B extends A implements I2{
public void p(){
} //end p()
//-----//

public void q(){
} //end q();
//-----//
} //end class B

```

Table 3.60**Implementing an interface**

Listing 3 (p. 379) defines a class named **B** , which *extends* the class named **A** , and *implements* the interface named **I2** .

As you already know, a class in Java can extend only one other class. However, a Java class can implement any number of interfaces. (Multiple inheritance is allowed with interfaces.)

Similar to an abstract class

An interface is similar, but not identical, to an **abstract** class. (*An abstract class may contain abstract methods or concrete methods, or a combination of the two while all of the methods in an interface are implicitly abstract.*)

Restrictions

An abstract class cannot be instantiated. Thus, an abstract class is only useful when it is extended by another class.

An interface also cannot be instantiated.

Implicitly abstract methods

As mentioned above, all methods declared in an interface are implicitly abstract, but that is not true for an abstract class. An abstract class can also contain fully-defined (*concrete*) methods. Regardless, an abstract class cannot be instantiated.

A totally abstract class

At the risk of offending the purists, I will coin a new term here and say that an interface is similar to a totally abstract class (*one that contains only abstract method declarations and final variables*) .

To a first degree of approximation then, we might say that the class named **B** is not only a subclass of the class named **A** , it is also a subclass of the *totally abstract* class named **I2** . (*This is pretty far out with respect to terminology, so to avoid being embarrassed, you probably shouldn't repeat it to anyone else.*)

Since **I2** extends **I1** , we might also say that the class named **B** is a subclass of the *totally abstract* class named **I1** .

A different kind of thinking

With this kind of thinking, we have suddenly make it possible for Java classes to support *multiple inheritance* , with the stipulation that all but one of the inherited classes must be *totally abstract classes* .

Be very careful with this way of thinking

However, we need to be very careful with this kind of thinking. While it may help some students to understand the role of interfaces in Java, there are probably some hidden dangers lurking here.

Back to the safety zone

The safest course of action is to simply say that the class named **B** :

- Extends the class named **A**
- Implements the interface named **I2** directly
- Implements the interface named **I1** through inheritance

Java does not support multiple inheritance, but it does allow you to extend one class and implement any number of interfaces.

The cardinal rule regarding interface implementation

The cardinal rule in implementing interfaces is:

If a class implements an interface, it must provide a concrete definition for all the methods declared by that interface, and all the methods inherited by that interface. Otherwise, the class must be declared abstract and the definitions must be provided by a class that extends the abstract class.

The cardinal rule regarding class inheritance

A similar rule exists for defining classes that inherit abstract methods from other classes:

If a class inherits one or more abstract methods from its superclasses, it must provide concrete definitions for all the inherited abstract methods. Otherwise, the class must be declared abstract and the concrete definitions must be provided by a class that extends the abstract class.

What does that mean in this case?

In this case, this means that the class named **B** must provide concrete definitions for the methods named **p** and **q** , because:

- The class named **B** implements the interface named **I2** .
- The method named **q** is declared in the interface named **I2** .
- The interface named **I2** extends the interface named **I1** .

- The method named `p` is declared in the interface named `I1`.

As in method overriding, the signature of the concrete method in the defining class must match the signature of the method as it is declared in the interface.

Class B satisfies the cardinal rule

As you can see from Listing 3 (p. 379), the class named `B` does provide concrete (but empty) definitions of the methods named `p` and `q`.

(As mentioned earlier, I made the methods empty in this program for simplicity. However, it is not uncommon to define empty methods in classes that implement interfaces that declare a large number of methods, such as the `MouseListener` interface. See my tutorials on event-driven programming here ¹²³ for examples.)

The class named C

Listing 4 (p. 381) defines a class named `C`, which extends `Object`, and also implements `I2`. As in the case of the class named `B`, this class must, and does, provide concrete (but empty) definitions for the methods named `p` and `q`.

Listing 4 . Definition of the class named C.

```
class C extends Object implements I2{
public void p(){
} //end p()
//-----//

public void q(){
} //end q();
//-----//
} //end class C
```

Table 3.61

A driver class

Finally, the driver class named `Poly05` shown in Listing 5 (p. 381) defines an empty `main` method.

Listing 5 . The driver class named Poly05.

```
public class Poly05{
public static void main(String[] args){
} //end main
} //end class Poly05
```

Table 3.62

Doesn't do anything

As mentioned earlier, the purpose of this program is solely to illustrate an inheritance and interface structure. This program can be compiled and executed, but it doesn't do anything useful.

¹²³http://cnx.org/contents/-2RmHFs_:qfO9iJX-

A new relationship

At this point, it might be useful for you to sketch out the structure in a simple hierarchy diagram.

If you do, you will see that implementation of the interface named **I2** by the classes named **B** and **C**, has created a relationship between those two classes that is totally independent of the normal class hierarchical relationship.

What is the new relationship?

By declaring that both of these classes implement the same interface named **I2**, we are guaranteeing that an object of either class will contain concrete definitions of the two methods declared in the interfaces named **I2** and **I1**.

Furthermore, we are guaranteeing that objects instantiated from the two classes can be treated as the common type **I2**.

(**Important**: references to any objects instantiated from classes that implement **I2**, can be stored in reference variables of the type **I2**, and any of the interface methods can be called on those references.)

We know the user interface

The signatures of the interface methods in the two classes must match the signatures declared in the interfaces.

This means that if we have access to the documentation for the interfaces, we also know the signatures of the interface methods for objects instantiated from any class that implements the interfaces.

Different behavior

However, and this is extremely important, the behavior of the interface methods as defined in the class named **B** may be (*and often will be*) entirely different from the behavior of the interface methods having the same signatures as defined in the class named **C**.

Possibly the most powerful concept in Java

This is possibly the most powerful (*and most difficult*) concept embodied in the Java programming language.

If you don't understand interfaces ...

I usually tell my students several times each semester that if they don't understand interfaces, they don't really understand Java.

It is unlikely that you will ever be successful as a Java programmer without an understanding of interfaces.

There are very few worthwhile programs that can be written in Java without an understanding of interfaces.

The core aspect

So, what is the core aspect of this concept that is so powerful?

I told you earlier that each interface definition constitutes a new type. As a result, a reference to any object instantiated from any class that implements a given interface can be treated as the type of the interface.

So what!

When a reference to an object is treated as an interface type, any method declared in, or inherited into that interface can be called on the reference to the object.

However, the behavior of the method when called on references to different objects of the same interface type may be very different. In the current jargon, the behavior is *appropriate for the object on which it is called*.

One object, many types

Furthermore, because a single class can implement any number of different interfaces, a single object instantiated from a given class can be treated as any of the interface types implemented by the class from which it is instantiated. Therefore, a single object in Java can be treated as many different types.

(*However, when an object is treated as an interface type, only those methods declared in that interface can be called on the object. To call other methods on the object, it necessary to cast the object's reference to a different type.*)

Treating different types of objects as a common type

All of this also makes it possible to treat objects instantiated from widely differing classes as the same type, provided that all of those classes implement the same interface.

Important : When an interface method is called on one of the objects using the reference of the interface type, the behavior of the method will be as defined by the author of the specific class that implemented the interface. The behavior of the method will often be different for different objects instantiated from different classes that implement the same interface.

Receiving parameters as interface types

Methods can receive parameters that are references of interface types. In this case, the author of the code that calls interface methods on the incoming reference doesn't need to know, and often doesn't care, about the name of the class from which the object was instantiated. (*For a discussion of this capability, see my tutorials on the Java Collections Framework, which you can read about here* ¹²⁴ .)

A common example

A very common example is to store references to objects instantiated from different classes, (*which implement the same interface*) in some sort of data structure (*such as list or a set*) and then to call the same methods on each of the references in the collection.

Heart of the Delegation Event Model

For example, this methodology is at the heart of the *Delegation Event Model* , which forms the basis of Graphical User Interfaces and event-driven programming in Java.

This often entails defining classes that implement standard interfaces such as **MouseListener** , **WindowListener** , **TextListener** , etc. In this case, the programmer defines the interface methods to be appropriate for a listener object instantiated from a specific class. Then a reference to the listener object is registered on an event source *as the interface type* .

Later when an event of that type occurs, the source object calls one or more interface methods on the listener object using the reference of the interface type. The event source object doesn't know or care about the class from which the object was instantiated. In fact, it doesn't even care how the interface method behaves when it is called. The responsibility of the source object ends when it calls the appropriate interface method on the listener object.

Model View Control

This same methodology is also critical to the use of the *Model View Control* paradigm in Java using the **Observer** interface and the **Observable** class. In this case, view objects instantiated from different classes that implement the **Observer** interface can register themselves on a model object that extends the **Observable** class. Then each time the data being maintained in the model changes, each of the views will be notified so that they can update themselves.

JavaBeans Components

This concept is also critical to the use of *bound* and *constrained* properties in JavaBeans Components. One bean can register itself on other beans to be notified each time the value of a bound or constrained property changes. In the case of constrained properties, the bean that is notified has the option of vetoing the change.

Java Collections Framework

The Java Collections Framework is also totally dependent on the use of interfaces. As I mentioned earlier, you can read all about this in my tutorials on the Java Collections Framework, which you can read about here ¹²⁵ .

Iterators and Enumerators

If you appreciate data structures, you will also appreciate iterators. In Java, **Iterator** is an interface, and an object that knows how to iterate across a data structure is an object of a class that implements the **Iterator** interface.

As a result, the users of the concrete implementations in the Java Collections Framework don't need to know any of the implementation details of the collection to create and use an iterator. All of the work necessary to properly create an iterator is done by the author of the class that implements the appropriate

¹²⁴<http://cnx.org/contents/dzOvxPFw:BaPSYl18>

¹²⁵<http://cnx.org/contents/dzOvxPFw:BaPSYl18>

Collection interfaces. All the user needs to understand is the behavior of the three methods declared in the **Iterator** interface.

3.2.9.5 Summary

Polymorphic behavior, based on the Java interface, is one of the most important concepts in Java OOP

In this module, I began my discussion of runtime polymorphism as implemented using method overriding and the Java interface.

I presented a simple skeleton program that illustrated many of the important aspects of polymorphic behavior based on the Java interface.

By using a nonstandard notation of my own design, (*a totally abstract class*), I explained how the implementation of interfaces in Java is similar to multiple inheritance.

I explained the cardinal rule, which is:

If a class implements an interface, it must provide a concrete definition for all the methods declared by that interface, and all the methods inherited by that interface. Otherwise, the class must be declared abstract and the definitions must be provided by a class that extends the abstract class.

I explained that objects instantiated from classes that implement the same interface have a new relationship that goes beyond the relationship imposed by the standard class hierarchy.

I explained that due to the combination of the class hierarchy and the fact that a class can implement many different interfaces, a single object in Java can be treated as many different types. However, for any given type, there are restrictions on the methods that can be called on the object.

I also explained that because different classes can implement the same interface, objects instantiated from different classes can be treated as a common interface type.

I suggested that there is little if anything useful that can be done in Java without understanding and using interfaces.

Finally I discussed some real-world examples of the use of the Java interface:

- Delegation event model
- Model View Control paradigm
- Bound and constrained properties in JavaBeans Components
- Java Collections Framework Iterators and Enumerators

3.2.9.6 What's next?

In the next module, I will explain a more substantive program as I continue my discussion of polymorphic behavior using the Java interface.

Method overloading

I covered method overloading as one form of polymorphism (*compile-time polymorphism*) in a previous module.

Method overriding and class inheritance

I discussed *runtime polymorphism* implemented through method overriding and class inheritance in more than one previous module.

Using the Java interface

In this and the previous module, I am explaining runtime polymorphism as implemented using method overriding and the Java interface.

A very important concept

In my opinion, this is one of the most important concepts in Java OOP, and the one that seems to give students the greatest amount of difficulty. Therefore, I am trying to take it slow and easy. As usual, I am illustrating the concept using sample programs.

A skeleton program

In the previous module, I presented a simple skeleton program that illustrated many of the important aspects of polymorphic behavior based on the Java interface.

Multiple inheritance and the cardinal rule

I explained how the implementation of interfaces in Java is similar to multiple inheritance. I explained the cardinal rule of interface implementation.

A new relationship

I explained that objects instantiated from classes that implement the same interface have a new relationship that goes beyond the relationship imposed by the standard class hierarchy.

One object, many types

I explained that due to the combination of the class hierarchy and the fact that a class can implement many different interfaces, a single object in Java can be treated as many different types. However, for any given type, there are restrictions on the methods that can be called on the object.

Many classes, one type

I explained that because different classes can implement the same interface, objects instantiated from different classes can be treated as a common interface type.

Interfaces are critical to Java programming

I suggested that there is little if anything useful that can be done in Java without understanding and using interfaces. In support of this suggestion, I discussed several real-world examples of the use of the Java interface, including the Delegation Event Model and the Model View Control paradigm.

Another sample program

In this module, I will present another sample program that will take you deeper into the world of polymorphism as implemented using the Java interface.

The sample program that I will discuss in this module will illustrate (*in a very basic form*) some of the things that you can do with interfaces, along with some of the things that you cannot do with interfaces. In order to write programs that do something worthwhile, you will need to extend the concepts illustrated by this sample program into real-world requirements.

3.2.10.4 Discussion and sample code

Now, let's take a look at a sample program named **Poly06** that is much simpler than any of the real-world examples that you will see in future modules.

This program is designed to be very simple, while still illustrating runtime polymorphism using interfaces, class inheritance, and overridden methods.

You can view a complete listing of the program in Listing 15 (p. 398) near the end of the module.

Same structure as before

Note that this program has the same structure as **Poly05** discussed in the previous module ¹²⁹. (*I strongly recommend that you study the previous module before continuing with this module.*) However, unlike the program in the previous module, the methods in this version of the program are not empty. When a method is called in this version, something happens. (*Admittedly not much happens. Text is displayed on the computer screen, but that is something.*)

The interface definitions

Listing 1 (p. 389) shows the definition of the two interfaces named **I1** and **I2**.

Listing 1 . Definition of the interfaces named I1 and I2.

```

    interface I1{
    public void p();
    }//end interface I1

//=====//

interface I2 extends I1{
    public void q();
    }//end interface I2

```

Table 3.64

Since the methods declared in an interface are not allowed to have a body, these interface definitions are identical to those shown in the program from the previous module.

The class named A

Similarly, Listing 2 (p. 389) shows the definition of the class named **A** along with the definition of the method named **x**, and the overridden method named **toString**.

Listing 2 . Definition of the class named A.

```

    class A extends Object{

    public String toString(){
        return "toString in A";
    }//end toString()
    //-----//

    public String x(){
        return "x in A";
    }//end x()
    //-----//
    }//end class A

```

¹²⁹<http://cnx.org/contents/dzOvxPFw:LAUK4UwQ>

Table 3.65

These two methods were also fully defined in the program from the previous module, so there is no change here either.

The method named B

Listing 3 (p. 390) defines the class named **B** , which extends **A** , and implements **I2** .

Listing 3 . Definition of the class named B.

```

class B extends A implements I2{
public void p(){
    System.out.println("p in B");
} //end p()
//-----//

public void q(){
    System.out.println("q in B");
} //end q();
//-----//
} //end class B

```

Table 3.66

Actually implements two interfaces

Although it isn't obvious from an examination of Listing 3 (p. 390) alone, the class named **B** actually implements both **I2** and **I1** . This is because the interface named **I2** extends **I1** . Thus, the class named **B** implements **I2** directly, and implements **I1** through interface inheritance.

The cardinal rule

In case you have forgotten it, the cardinal rule for implementing interfaces is:

If a class implements an interface, it must provide a concrete definition for all the methods declared by that interface, and all the methods inherited by that interface. Otherwise, the class must be declared abstract and the definitions must be provided by a class that extends the abstract class.

Must define two methods

As a result, the class named **B** must provide concrete definitions for the methods **p** and **q** . (*The method named **p** is declared in interface **I1** and the method named **q** is declared in interface **I2** .*)

As you can see from Listing 3 (p. 390) , the behavior of each of these methods is to display a message indicating that it has been executed. This will be useful later to tell us exactly which method is executed when we exercise the objects in the **main** method of the driver class.

The class named C

Listing 4 (p. 390) shows the upgraded version of the class named **C** .

Listing 4 . Definition of the class named C.

continued on next page

```

    class C extends Object implements I2{
public void p(){
    System.out.println("p in C");
} //end p()
//-----//

public void q(){
    System.out.println("q in C");
} //end q();
//-----//
} //end class C

```

Table 3.67

In this upgraded version, the methods named **p** and **q** each display a message indicating that they have been executed. Again, this will be useful later to let us know exactly which version of the methods named **p** and **q** get executed when we exercise the objects.

The driver class

Listing 5 (p. 391) shows the beginning of the class named **Poly06**. The **main** method in this class instantiates objects of the classes named **B** and **C**, and exercises them to illustrate what can, and what cannot be done with them.

Listing 5 . Beginning of the class named Poly06.

```

public class Poly06{
public static void main(
    String[] args){
    I1 var1 = new B();
    var1.p();//OK

```

Table 3.68

A new data type

As explained in the previous module, when you define a new interface, you create a new data type.

You can store the reference to any object instantiated from any class that implements the interface in a reference variable of that type.

A new object of the class B

The code shown in Listing 5 (p. 391) instantiates a new object of the class **B**.

Important: stored as type I1

It is important to note that the code in Listing 5 (p. 391) stores the object's reference in a reference variable of the interface type **I1** (*not as the class type B*).

Call an interface method

Following this, the code in Listing 5 (p. 391) successfully calls the method named **p** on the reference, producing the following output on the computer screen:

```
p in B
```

Why is this allowed?

This is allowable because the method named `p` is declared in the interface named `I1` .

Which version of the method was executed?

It is also important to note, (*by observing the output*) , that the version of the method defined in the class named `B` (*and not the version defined in the class named `C`*) was actually executed.

Attempt unsuccessfully to call `q`

Next, the code in Listing 6 (p. 392) attempts, unsuccessfully, to call the method named `q` on the same reference variable of type `I1` .

Listing 6 . Try unsuccessfully to call the method named `q`.

```
var1.q();//won't compile
```

Table 3.69**Why did it fail?**

Even though the class named `B` , from which the object was instantiated, defines the method named `q` , that method is neither declared nor inherited into the interface named `I1` .

Therefore, a reference of type `I1` cannot be used to call the method named `q` .

The solution is a type conversion

Listing 7 (p. 392) shows the solution to the problem presented by Listing 6 (p. 392) .

Listing 7 . Successfully call the method named `q`.

```
((I2)var1).q();//OK
```

Table 3.70

As in the case of polymorphism involving class inheritance, the solution is to change the type of the reference to a type that either declares or inherits the method named `q` .

In this case, this takes the form of using a cast operator to temporarily convert the type of the reference from type `I1` , to type `I2` , and then calling the method named `q` on that reference of a new type.

This produces the following output:

```
q in B
```

Using type `I2` directly

Listing 8 (p. 392) instantiates a new object of the class `B` and stores the object's reference in a reference variable of the interface type `I2` .

Listing 8 . Instantiate a new object of the class `B`.

continued on next page

```
I2 var2 = new B();
var2.p();//OK
var2.q();//OK
```

Table 3.71

Call both methods successfully

Then the code successfully calls both the methods `p` and `q` on that reference, producing the following output:

```
p in B
q in B
```

Why does this work?

This works because:

- The interface named `I2` declares the method named `q`
- The interface named `I2` inherits the declaration of the method named `p`
- The class named `B` implements the interface named `I2` and provides concrete definitions of both the methods `p` and `q`.

Attempt, unsuccessfully, to call `x` on `var2`

Following this, the code in Listing 9 (p. 393) attempts, unsuccessfully, to call the method named `x` on the reference variable named `var2` of type `I2`. This code produces a compiler error.

Listing 9 . Try unsuccessfully to call the method named `x`.

```
String var3 = var2.x();
```

Table 3.72

The object of class `B` has a method named `x`

At this point, the reference variable named `var2` contains a reference to an object instantiated from the class named `B`.

Furthermore, the class named `B` inherits the method named `x` from the class named `A`.

Necessary, but not sufficient

However, the fact that the object contains the method is not sufficient to make it executable in this case.

Same song, different verse

The interface named `I2` neither declares nor inherits the method named `x`.

Therefore, the method named `x` cannot be called using the reference stored in the variable named `var2` unless the reference is converted either to type `A` (where the method named `x` is defined) or type `B` (where the method named `x` is inherited).

Do the type conversion

The required type conversion is accomplished in Listing 10 (p. 394) where the reference is temporarily converted to type `A` using a cast operator. (It would also work to cast it to type `B`.)

Listing 10 . Successfully call the method named x.

```
String var3 = ((A)var2).x();//OK
System.out.println(var3);
```

Table 3.73

The String produced by the first statement in Listing 10 (p. 394) is passed to the **println** method causing the following text to be displayed on the computer screen:

```
x in A
```

Get ready for a surprise

If you have now caught onto the general scheme of things, the next thing that I am going to show you may result in a little surprise.

Successfully call the toString method on var2

The first statement in Listing 11 (p. 394) successfully calls the **toString** method on the object of the class **B** whose reference is stored as type **I2** .

Listing 11 . Call the toString method.

```
var3 = var2.toString();//OK
System.out.println(var3);
```

Table 3.74**How can this work?**

How can this work when the interface named **I2** neither declares nor inherits a method named **toString** .

A subtle difference in behavior

I am unable to point you to any Oracle documentation to verify the following. (*I also admit that I haven't spent a large amount of time searching for such documentation*).

With respect to the eleven methods declared in the **Object** class (*listed in an earlier module*) , a reference of an interface type acts like it is also of type **Object** .

And the end result is ...

This allows the methods declared in the **Object** class to be called on references held as interface types without a requirement to cast the references to type **Object** . (*Later, I will show you that the reverse is not true.*)

The output

Therefore, the two statements shown in Listing 11 (p. 394) cause the following to be displayed on the computer screen:

```
toString in A
```

Polymorphism applies

Note that the object whose reference is held in **var2** was instantiated from the class named **B** , which extends the class named **A** .

Due to polymorphism, the `toString` method that was actually executed in Listing 11 (p. 394) was the overridden version defined in class `A`, and not the default version defined in the `Object` class. The overridden version in class `A` was inherited into class `B`.

The reverse is not true

While a reference of an interface type also acts like type `Object`, a reference of type `Object` does not act like an interface type.

Store a reference as type `Object`

The code in Listing 12 (p. 395) instantiates a new object of type `B` and stores it in a reference of type `Object`.

Attempt unsuccessfully to call `p`

Then it attempts, unsuccessfully, to call the method named `p` on the reference.

Listing 12 . Try unsuccessfully to call the method named `p`.

```
Object var4 = new B();
var4.p(); //won't compile
```

Table 3.75

Same song, an even different verse

The code in Listing 12 (p. 395) won't compile, because the `Object` class neither defines nor inherits the method named `p`.

In order to call the method named `p` on the reference of type `Object`, the type of the reference must be changed to either:

- The class in which the method is defined
- An interface that declares the method, which is implemented by the class in which the method is defined
- A couple of other possibilities involving subclasses or sub-interfaces

Convert reference to type `I1`

The code in Listing 13 (p. 395) uses a cast operator to temporarily convert the reference from type `Object` to type `I1`, and calls the method named `p` on the converted reference.

Listing 13 . Successfully call the method named `p`.

```
((I1)var4).p(); //OK
```

Table 3.76

The output

The code in Listing 13 (p. 395) compiles and executes successfully, producing the following text on the computer screen:

```
p in B
```

A walk in the park

If you understand all of the above, understanding the code in Listing 14 (p. 396) should be like a walk in the park on a sunny day.

Listing 14. A walk in the park.

```

var2 = new C();
var2.p();//OK
var2.q();//OK

```

Table 3.77**Class C implements I2**

Recall that the class named **C** also implements the interface named **I2**.

The code in Listing 14 (p. 396) instantiates a new object of the class named **C**, and stores the object's reference in the existing reference variable named **var2** of type **I2**.

Then it calls the methods named **p** and **q** on that reference, causing the following text to be displayed on the computer screen:

```

p in C
q in C

```

Which methods were executed?

This confirms that the methods that were actually executed were the versions defined in the class named **C** (*and not the versions defined in the class named **B***).

Same method name, different behavior

It is important to note that the behavior of the methods named **p** and **q**, as defined in the class named **C**, is different from the behavior of the methods having the same signatures defined in the class named **B**. Therein lies much of the power of the Java interface.

The power of the Java interface

Using interface types, it is possible to collect many objects instantiated from many different classes (*provided all the classes implement a common interface*), and store each of the references in some kind of collection as the interface type.

Appropriate behavior

Then it is possible to call any of the interface methods on any of the objects whose references are stored in the collection.

To use the current jargon, when a given interface method is called on a given reference, the behavior that results will be *appropriate* to the class from which that particular object was instantiated.

This is runtime polymorphism based on interfaces and overridden methods.

3.2.10.5 Summary**If you don't understand interfaces ...**

If you don't understand interfaces, you don't understand Java, and it is highly unlikely that you will be successful as a Java programmer.

Interfaces are indispensable in Java

Beyond writing "Hello World" programs, there is little if anything that can be accomplished using Java without understanding and using interfaces.

What can you do with interfaces?

The sample program that I discussed in this module has illustrated (*in a very basic form*) some of the things that you can do with interfaces, along with some of the things that you cannot do with interfaces.

In order to write programs that do something worthwhile, you will need to extend the concepts illustrated by this sample program into real-world requirements.

3.2.10.6 What's next?

Java supports the use of **static** member variables and **static** methods in class definitions.

While **static** members can be useful in some situations, the existence of **static** members tends to complicate the overall object-oriented structure of Java.

Furthermore, the overuse of **static** members can lead to problems similar to those experienced in languages like C and C++ that support global variables and global functions.

The use of static members will be discussed in the next module.

Static members

There is another aspect of OOP in Java that I have avoided up to this point in the discussion: **static** variables and **static** methods.

Tends to complicate ...

I have avoided this topic because, while not particularly difficult, the existence of **static** members tends to break up the simple structures that I have discussed in previous modules in this collection.

While **static** members can be useful in some situations, the existence of **static** members tends to complicate the overall object-oriented structure of Java.

Avoid overuse of static members

Furthermore, the overuse of **static** members can lead to problems similar to those experienced in languages like C and C++ that support global variables and global functions.

When to use static members

I will discuss the use of **static** members in this module, and will provide some guidelines for their use.

The class named Class

I will also introduce the class named **Class** and discuss how it enters into the use of **static** variables and methods.

Instance members versus class members

I will describe the differences between *instance* members and *class* members with particular emphasis being placed on their accessibility.

Three kinds of objects

From a conceptual viewpoint, there are at least three kinds of objects involved in a Java program:

- Ordinary objects
- Array objects
- Class objects

Ordinary objects

All (*or at least most*) of the discussion up to this point in the collection deals with what I have referred to in the above list as *ordinary objects* .

These are the objects that you instantiate in you code by applying the **new** operator to a constructor for a class in order to create a new instance (*object*) of that class. (*There are also a couple of other ways to create ordinary objects, but I'm not going to get into that at this time.*)

Array objects

I haven't discussed *array objects* thus far in this collection. (*I will discuss them in a future module.*)

Suffice it for now to say that array objects are objects whose purpose is to encapsulate a one-dimensional array structure that can contain either primitive values, or references to other objects (*including other array objects*).

I will discuss Class objects in this module.

3.2.11.4 Discussion and sample code

Class objects

Let me emphasize at the beginning that the following discussion is **conceptual** in nature. In this discussion, I will describe how the Java system behaves, not necessarily how it is implemented. In other words, however it is implemented, it behaves as though it is implemented in the manner described below.

The class named `Class`

There is a class whose name is `Class`. The purpose of this class is to encapsulate information about some other class (*actually, it can also be used to encapsulate information about primitive types as well as class types*).

Here is part of what Sun has to say about this class:

"Instances of the class `Class` represent classes and interfaces in a running Java application. ...

`Class` has no public constructor. Instead `Class` objects are constructed automatically by the Java Virtual Machine as classes are loaded ..."

What does this mean?

As a practical matter, when one or more objects are instantiated from a given class, an extra object of the `Class` class is also instantiated automatically. This object contains information about the class from which the objects were instantiated. (*Note that it is also possible to cause a `Class` object that describes a specific class to be created in the absence of objects of that class, but that is a topic that will be reserved for more advanced modules.*)

A real-world analogy

Here is an attempt to describe a real-world analogy. Remember that a class definition contains the blueprint for objects instantiated from that class.

A certain large construction company is in the business of building condominium projects. This contractor builds condos of many different sizes, types, and price ranges. However, each different condo project contains condos of only two or three different types or price ranges.

A library of blueprints

There is a large library of blueprints at the contractor's central office. This library contains blueprints for all of the different types of condos that the contractor has built or is building. (*This library is analogous to the class libraries available to the Java programmer.*)

A subset from the blueprint library

When a condo project begins, the contractor delivers copies of several sets of blueprints to the construction site. The blueprints delivered to that site describe only the types of condos being constructed on that site.

Condo is analogous to an object

Each condo unit is analogous to an *ordinary Java object*.

Each set of blueprints delivered to the construction site is roughly analogous to an *object of the class named `Class`*. In other words, each set of blueprints describes one or more condo units constructed from that set of blueprints.

When construction is complete

When the construction project is complete, the contractor delivers a set of blueprints for each type of condo unit to the management firm that has been hired to manage the condo complex. Each set of blueprints continues to be analogous to an object of the class named `Class`. The blueprints remain at the site of the condo units.

RTTI

Thus, information regarding the construction, wiring, plumbing, air conditioning, etc., for each condo unit (*object*) continues to be available at the site even after the construction has been completed. (*This is*

somewhat analogous to something called runtime type information and often abbreviated as RTTI. A Class object contains RTTI for objects instantiated from that class.)

What are those analogies again?

In the above scenario, each condo unit is (*roughly*) analogous to an object instantiated from a specific class (*set of blueprints*).

Each set of blueprints remaining onsite after construction is complete is roughly analogous to a **Class** object that describes the characteristics of one or more condo units.

What do you care?

Until you get involved in such advanced topics as *reflection* and *introspection*, you don't usually have much involvement or much interest in **Class** objects. They are created automatically, and are primarily used by the Java virtual machine during runtime to help it do the things that it needs to do.

An exception to that rule

However, there is one area where you will be interested in the use of these **Class** objects from early on. You will be interested whenever variables or methods in the class definition are declared to be **static**.

Class variables and class methods

According to the current jargon, declaring a member variable to be **static** causes it to be a *class variable*. (*Note that local variables cannot be declared **static**. Only member variables can be declared **static**.*) Similarly, declaring a method to be **static** causes it to be a *class method*.

Instance variables and methods

On the other hand, according to the current jargon, not declaring a variable to be **static** causes it to be an *instance variable*, and not declaring a method to be **static** causes it to be an *instance method*.

In general, we can refer to them as *class members* and *instance members*.

What is the difference?

Here are some of the differences between *class* and *instance* members insofar as this discussion is concerned.

How many copies of member variables exist?

Every object instantiated from a given class has its own copy of each *instance variable* defined in the class. (*Instance variables are not shared among objects.*) However, every object instantiated from a given class shares the same copy of each *class variable* defined in the class. (*It is as though the class variable belongs to the single **Class** object and not to the individual objects instantiated from that class.*)

Access to an instance variable

Every object has its own copy of each instance variable (*the object owns the instance variable*). Therefore, the only way that you can access an instance variable is to use that object's reference to send a message to the object requesting access to the variable (*even then, you may not be given access, depending on access modifiers*).

Why call it an instance variable?

According to the current jargon, **an object is an instance of a class**. (*I probably told you that somewhere before in this collection.*) Each object has its own copy of each non-static variable. Hence, they are often called instance variables. (*Every instance of the class owns one and they are not implicitly shared among instances.*)

Access to a class variable

You can also send a message to an object requesting access to a class variable that the object shares with other objects instantiated from the same class. (*Again, you may or may not gain access, depending on the access modifiers*).

Access using the Class object

More importantly, you can also access a class variable without a requirement to go through an object instantiated from the class. (*In fact, a class variable can be accessed in the total absence of objects of that class.*) (*Remember, this discussion is conceptual in nature, and may not represent an actual implementation.*)

Assuming that a class variable is otherwise accessible, you can access the class variable by sending an access request message to the **Class** object to which the variable belongs.

One way to think of this

To help you keep track of things in a message-passing sense, you can pretend that there is a global reference variable whose name is the same as the name of a class.

This (*hypothetical*) reference variable contains a reference to the **Class** object that owns the class variable. Using standard Java message-passing syntax, you can access the class variable by joining the name of the reference variable to the name of the class variable with a period. Example syntax is shown below:

```
ReferenceVariableName.ClassVariableName
```

As a result of the hypothetical substitution process that I described above, this is equivalent to the following:

```
ClassName.ClassVariableName
```

We will see an example of this in the sample program that I will discuss later.

Be careful with this thought process

*While this thought process may be useful when thinking about **static** variables and methods, I want to point out, that the thought process breaks down very quickly when dealing with **Class** objects in a deeper sense.*

*For example, when calling the **getName** method on a **Class** object, an actual reference of type **Class** is required to access the members of the **Class** object. The name of the class will not suffice.*

If this discussion of a global reference variable whose name matches the name of the class is confusing to you, just forget it. Simply remember that you can access class variables by joining the name of the class to the name of the class variable using a period as the joining operator.

Characteristics of class methods

I'm not going to talk very much about instance methods and class methods in this module. However, there are a couple of characteristics of class methods that deserve a brief discussion in this context.

Cannot access instance members

First, the code in a class method has direct access only to other **static** members of the class. (*A class method does not have direct access to instance variables or instance methods of the class.*) This is sort of like saying that a class method has access to the methods and variables belonging to the **Class** object, but does not have access to the methods and variables belonging to the *ordinary objects* instantiated from the class described by the **Class** object.

Once again, be careful

*Once again, this thinking breaks down very quickly once you get beyond **static** members. A **Class** object also has instance methods, such as **getName**, which can only be accessed using an actual reference to the **Class** object.*

Now you are probably beginning to understand why I deferred this discussion until after I finished discussing the easy stuff.

No object required

Another important characteristic is that a class method can be accessed without a requirement for an object of the class to exist.

As with class variables, class methods can be accessed by joining the name of the class to the name of the method with a period.

I will illustrate much of this with a sample program named **MyClass01**.

Discuss in fragments

I will discuss the program in fragments. You will find a complete listing of the program in Listing 13 (p. 415) near the end of the module.

Listing 1 (p. 404) shows the beginning of the class definition.

Listing 1 . Beginning of the class named MyClass01.

```
class MyClass01{
static Date v1 = new Date();
Date v2 = new Date();
```

Table 3.79**Two member variables**

The code in Listing 1 (p. 404) declares two member variables, named **v1** and **v2**, and initializes each of those variables with a reference to a new object of the **Date** class. (*When instantiated using the constructor with no arguments, the new **Date** object encapsulates the current date and time from the system clock.*)

Note the static keyword

The important thing to note here is the use of the **static** keyword when declaring the variable named **v1**. This causes **v1** to be a *class variable*, exhibiting the characteristics of class variables described earlier.

An instance variable

On the other hand, the variable named **v2** is not declared **static**. This causes it to be an *instance variable*, as described above.

The main method is a class method

Listing 2 (p. 404) shows the signature for the **main** method.

Listing 2 . Signature of the main method.

```
public static void main(String[] args){
```

Table 3.80

The important thing to note here is that the **main** method is declared **static**. That causes it to be a *class method*.

As a result, the **main** method can be called without a requirement for an object of the class to exist. (*Also, the main method has direct access only to other **static** members.*)

How a Java application starts running

In fact, that is how the Java Virtual Machine starts an application running.

First the JVM finds the specified file having an extension of **.class**. Then it examines that file to see if it has a **main** method with the correct signature. If not, an error occurs.

If the JVM finds a **main** method with the correct signature, it calls that method without instantiating an object of the class. That is how the Java Virtual Machine causes a Java application to start running.

A side note regarding applets

*For those of you who are familiar with Java applets, you should know that this is not the case for an applet. An applet does not use a **main** method. When an applet is started, an object of the controlling class is instantiated by the browser, by the **appletviewer** program, or by whatever program is being used to control the execution of the applet.*

A poor programming technique

Basically, this entire sample program is coded inside the **main** method. As a practical manner, this is a very poor programming technique, but it works well for this example.

Display some text

The code in Listing 3 (p. 405) , which is the first executable statement in the **main** method, causes the words **Static variable** to appear on the computer screen. I will come back and discuss the details of this and similar statements later in the module.

Listing 3 . Display some text.

```
System.out.println("Static variable");
```

Table 3.81**Display date information**

Continuing with the code in the **main** method, the code in Listing 4 (p. 405) causes the current contents of the **Date** object referred to by the contents of the class variable named **v1** to be displayed on the computer screen.

Listing 4 . Display date information.

```
System.out.println(MyClass01.v1);
```

Table 3.82**No object required**

For the moment, concentrate on the text inside the parentheses in the statement in Listing 4 (p. 405) .

Because the variable named **v1** is a class variable, it's value is accessed by joining the name of the class to the name of the variable with a period.

What was the output?

I will discuss the remaining portion of statements of this sort later. For now, just be aware that the code in Listing 4 (p. 405) caused the output shown in Figure 1 (p. 405) to be displayed on my computer screen when I ran the program.

Figure 1 . Output date and time.

```
Mon Sep 17 09:52:27 CDT 2001
```

Table 3.83**Displays date and time**

Obviously, the date and time displayed will depend on when you run the program. As you can see, I first wrote this module and ran this program in 2001.

Pay particular attention to the seconds portion of the time. I will refer back to this later.

A five-second delay

The code in Listing 5 (p. 406) (*still in the **main** method*) causes the main thread of the program to go to sleep for five seconds. Don't worry about it if you don't understand this code. The only reason that I included it in the program was to force a five-second delay in the execution of the program.

Listing 5 . A five-second delay.

```

try{
    Thread.currentThread().sleep(5000);
}catch(InterruptedException e){}

```

Table 3.84**Instantiate a new object**

Having caused the program to sleep for five seconds, the code in Listing 6 (p. 406) instantiates a new object of the class named **MyClass01** . This code stores the new object's reference in the reference variable named **ref1** .

Listing 6 . Instantiate a new object .

```

MyClass01 ref1 = new MyClass01();

```

Table 3.85**A new Date object also**

Recall from Listing 1 (p. 404) above that the class declares an instance variable named **v2** of the type **Date** .

When the new object is instantiated by the code in Listing 6 (p. 406) , a new **Date** object is also instantiated. A reference to that object is stored in the instance variable named **v2** . *(In other words, the new object of the class **MyClass01** owns a reference to a new object of the class **Date** . That reference is stored in an instance variable named **v2** in the new **MyClass01** object.)*

Display the new Date object

The code in Listing 7 (p. 406) causes a textual representation of the new **Date** object referred to by the reference variable named **v2** belonging to the object referred to by the reference variable named **ref1** , to be displayed on the standard output device.

Listing 7 . Display the new Date object .

```

System.out.println(ref1.v2);

```

Table 3.86**Five seconds later**

This code caused the date and time shown in Figure 2 (p. 407) to appear on the computer screen when I ran the program:

Figure 2 . Five seconds later.

Mon Sep 17 09:52:32 CDT 2001

Table 3.87

The date and time shown in Figure 2 (p. 407) is five seconds later than the time reflected in the **Date** object referred to by the *class variable* named **v1** (see Figure 1 (p. 405)) . That time was displayed by the code in Listing 4 (p. 405) earlier.

So, what does this mean?

It means that the **Date** object referred to by the **static** reference variable named **v1** was created five seconds earlier than the **Date** object referred to by the instance variable named **v2** .

When is a class variable created?

I can't tell you precisely when a class variable comes into existence. All I can say is that the virtual machine brings it into existence as soon as it is needed.

My guess is that it comes into existence at the first mention (*in the program*) of the class to which it belongs.

When is an instance variable created?

An instance variable doesn't come into existence until the object to which it belongs is created. (*An instance variable cannot exist until the object to which it belongs exists.*)

If the instance variable is initialized with a reference to a new object (*such as a new **Date** object in this sample program*), that new object comes into existence when the object to which it belongs comes into existence.

A five-second delay

In this program, I purposely inserted a five-second delay between the first mention of the class named **MyClass01** in Listing 4 (p. 405) , and the instantiation of the object of the class named **MyClass01** in Listing 6 (p. 406) .

As a result, the **Date** object referred to by the instance variable named **v2** was created about five seconds later than the **Date** object referred to by the class variable named **v1** .

This is reflected in the date and time values displayed and discussed above.

Accessing class variable via an object

While it is possible to access a class variable using the name of the class joined to the name of the variable, it is also possible to access a class variable using a reference to any object instantiated from the class.

(*As mentioned earlier, if two or more objects are instantiated from the same class, they share the same class variable.*)

The code in parentheses in Listing 8 (p. 407) uses the reference variable named **ref1** to access the class variable named **v1** , and to cause the contents of the **Date** object referred to by the class variable to be displayed.

Listing 8 . Accessing class variable via an object.

<code>System.out.println(ref1.v1);</code>

Table 3.88**The output**

This caused the date and time shown in Figure 3 (p. 408) to be displayed on my computer screen.

Figure 3 . Same date and time as before.
Mon Sep 17 09:52:27 CDT 2001

Table 3.89**Same date and time as before**

As you have probably already surmised, this is the same date and time shown earlier in Figure 1 (p. 405) . This is because the code in Listing 8 (p. 407) refers to the same class variable as the code in Listing 4 (p. 405) .

Nothing has caused the contents of that class variable to change, so both Figure 1 (p. 405) and Figure 3 (p. 408) display the contents of the same **Date** object.

*(Only one class variable exists and it doesn't matter how you access it. Either way, you gain access to the same **Date** object whose reference is stored in the class variable. Thus, the same date and time is shown in both cases.)*

Another new object

If you examine the code in Listing 13 (p. 415) near the end of the program, you will see that an additional five-second delay is introduced at this point in the program.

Following that delay, the code in Listing 9 (p. 408) instantiates another new object of the class named **MyClass01** , and stores the object's reference in a new reference variable named **ref2** .

*(The object referred to by **ref1** is a different object than the object referred to by **ref2** . Each object has its own instance variable named **v2** , and in this case, each instance variable is initialized to instantiate and refer to a new **Date** object when the new **MyClass01** object is instantiated.)*

Listing 9 . Another new object .
<code>MyClass01 ref2 = new MyClass01();</code>

Table 3.90**Display the date and time**

Then, the code in Listing 10 (p. 408) causes the contents of the **Date** object referred to by the instance variable named **v2** in the second object of the class named **MyClass01** to be displayed.

Listing 10 . Display the date and time .
<code>System.out.println(ref2.v2);</code>

Table 3.91

This caused the output shown in Figure 4 (p. 409) to be displayed on my computer screen when I ran the program.

(Once again, you will get different results if you compile and run the program because the date and time shown is the date and time that you run the program.)

Figure 4 . A new date and time.

Mon Sep 17 09:52:37 CDT 2001

Table 3.92**Five seconds later**

As you have probably figured out by now, the time encapsulated in this `Date` object is five seconds later than the time encapsulated in the `Date` object displayed in Figure 2 (p. 407) . This is because the program was put to sleep for five seconds between the instantiation of the two objects referred to by `ref1` and `ref2` .

Every object has one

Every object instantiated from a given class has its own copy of each instance variable declared in the class definition. There is no sharing of instance variables among objects.

Each instance variable comes into existence when the object to which it belongs comes into existence, and ceases to exist when the object to which it belongs ceases to exist.

Eligible for garbage collection

If the instance variables are reference variables holding references to other objects, as is the case here, and if there are no other reference variables holding references to those same objects, the secondary objects cease to exist when the primary objects cease to exist.

Technically, the objects may not actually cease to exist. Technically they become eligible for garbage collection, which means that the memory that they occupy becomes eligible for reuse. However, as a practical matter, they cease to exist insofar as the program is concerned because they are no longer accessible.

A five-second difference in the time of creation

Since the two objects referred to by `ref1` and `ref2` came into existence with a five-second delay, the `Date` objects belonging to those two object reflect a five-second difference in the time encapsulated in the objects.

Only one copy of class variable exists

Also remember that if a variable is a class variable, only one copy of the variable exists, and all objects instantiated from the class share that one copy.

This is illustrated by the code in Listing 11 (p. 409) , which uses the reference to the second object instantiated from the class named `MyClass01` , to cause the contents of the class variable named `v1` to be displayed.

Listing 11 . Display date information.

<pre> System.out.println(ref2.v1); } //end main </pre>
--

Table 3.93

The output produced by the code in Listing 11 (p. 409) is shown in Figure 5 (p. 410) .

Figure 5 . Same date and time as before.

Mon Sep 17 09:52:27 CDT 2001

Table 3.94**Same output as before**

As you can see, this is the same as the output shown in Figure 1 (p. 405) and Figure 3 (p. 408) earlier.

Accessing the same physical class variable

Since only one class variable named `v1` exists, and all objects instantiated from the class named `MyClass01` share that single copy, it doesn't matter whether you access the class variable using the name of the class, or access it using a reference to either of the objects instantiated from the class. In all three cases, you are accessing the same physical class variable.

Since nothing was done to cause the contents of the class variable to change after it came into existence and was initialized, Figure 1 (p. 405) , Figure 3 (p. 408) , and Figure 5 (p. 410) are simply three different displays of the date and time encapsulated in the same `Date` object whose reference is stored in the class variable.

Let's revisit System.out.println...

Now, I want to revisit the statement originally shown in Listing 8 (p. 407) and repeated in Listing 12 (p. 410) for viewing convenience.

Listing 12 . Revisiting System.out.println.

<code>System.out.println(ref1.v1);</code>

Table 3.95**Java programmer wanted**

I sometimes tell my students that if I were out in industry interviewing prospective Java programmers, my first question would be to ask the prospective employee to tell me everything that she knows about the statement in Listing 12 (p. 410) .

Covers a lot of Java OOP technology

This is not because there is a great demand for the use of this statement in real-world problems. (*In fact, in a GUI-driven software product world, there is probably very little demand for the use of this statement.*) Rather, it is because a lot of Java object-oriented technology is embodied in this single statement.

In that scenario, I would expect to receive a verbal dissertation of fifteen to twenty minutes in length to cover all the important points.

The short version

Let me give you the short version. There is a class named `System` . The `System` class declares three `static` (*class*) variables having the following types, names, and modifiers:

- `public static final PrintStream out`
- `public static final InputStream in`
- `public static final PrintStream err`

(*Note that these class variables are also declared `final` , causing them to behave as constants.*)

A ccess the out variable without an object

Because `out` is a class variable, `System.out` returns the contents of the class variable named `out` (an object of the `System` class is not required in order to access a class variable of the `System` class).

In general, (ignoring the possibility of subclasses and interfaces) because `out` is a reference variable of type `PrintStream`, the returned value must either be `null` (no object reference) or a reference to a valid `PrintStream` object.

Object of the `PrintStream` class

When the Java Virtual Machine starts an application running, it automatically instantiates an object of the `PrintStream` class and connects it to the **standard output device**. (By default, the standard output device is typically the computer screen, but it can be redirected at the operating system level to be some other device. The following discussion assumes that the screen is the standard output device.)

Assign object's reference to `out` variable

When the `PrintStream` object is instantiated by the virtual machine, the object's reference is assigned to the class variable of the `System` class named `out`. (Because the variable named `out` is final, the contents of the variable cannot be modified later.)

Reference to a `PrintStream` object

Therefore, the expression `System.out` returns a reference to the `PrintStream` object, which is connected to the standard output device.

Many instance methods

An object of the `PrintStream` class contains many instance methods. This includes numerous overloaded versions of a method named `println`. The signature of one of those overloaded **versions of the `println` method** follows :

```
public void println(Object x)
```

Textual representation of an object

The purpose of this overloaded version of the `println` method is to:

- Create a textual representation of the object referred to by the incoming parameter of type `Object` (because `Object` is a totally generic type, this version of the `println` method can accept an incoming parameter that is a reference to any type of object)
- Send that textual representation to the output device

In general...

A new `PrintStream` object can be connected to a variety of output devices when it is instantiated. However, in the special case of the `PrintStream` object instantiated by the virtual machine when the program starts, whose reference is stored in the class variable named `out` of the `System` class, the purpose of the object is to provide a display path to the standard output device.

Our old friend, the `toString` method

To accomplish this, the code in the version of the `println` method shown above (p. 411) calls the `toString` method on the incoming reference. (I discussed the `toString` method in detail in earlier modules in this collection.) The `toString` method may, or may not, have been overridden in the definition of the class from which the object was instantiated, or in some superclass of the class from which the object was instantiated.

Default version of `toString`

If not overridden, the default version of the `toString` method defined in the `Object` class is used to produce a textual representation of the object. As we learned in an earlier module, that textual representation looks something like the following:

```
ClassName@HexHashCode
```

Overridden version of `toString` method

If the class from which the object was instantiated (or some superclass of that class) contains an overridden version of the `toString` method, runtime polymorphism kicks in and the overridden version of the method is executed to produce the textual representation of the object.

The Date class overrides toString

In the case of this sample program, the object was instantiated from the `Date` class. The `Date` class does override the `toString` method.

When the overridden `toString` method is called on a `Date` object's reference, the `String` returned by the method looks something like that shown in Figure 6 (p. 412) .

You will recall that this is the output that was produced by the code shown in Listing 8 (p. 407) and Listing 12 (p. 410) .

More than you ever wanted to know ...

And that is probably more than you ever wanted to know about the expression `System.out.println...`

It is also probably more than you ever wanted to know about class variables, class methods, instance variables, and instance methods.

Some cautions

Before leaving this topic, I do want to express some cautions. Basically, I want to suggest that you use `static` members very sparingly, if at all.

Static variables

To begin with, don't ever use `static` variables without declaring them `final` unless you understand exactly why you are declaring them `static` .

(`static final` variables, or constants, are often very appropriate. See the fields in the `Color` class for example.)

I can think of only a very a few situations in which the use of a non-final `static` variable might be appropriate.

(One appropriate use might be to count the number of objects instantiated from a specific class.)

Static methods

Don't declare methods `static` if there is any requirement for the method to remember anything from one call to the next.

There are many appropriate uses for `static` methods, but in most cases, the purpose of the method will be to completely perform some action with no requirement to remember anything from that call to the next.

The method should probably also be self-contained. By this I mean that all information that the method needs to do its job should either come from incoming parameters or from `final static` member variables (*constants*). The method probably should not depend on the values stored in non-final `static` member variables, which are subject to change over time.

(A `static` method only has access to other `static` members of the class, so it cannot depend on instance variables defined in the class.)

An appropriate example of a `static` method is the `sqrt` method of the `Math` class. This method computes and *"Returns the correctly rounded positive square root of a double"* where the `double` value is provided as a parameter to the method. Each time the method is called, it completes its task and doesn't attempt to save any values from that call to the next. Furthermore, it gets all the information that it needs to do its job from an incoming parameter.

3.2.11.5 Summary

Added complexity

The existence of **static** members tends to break up the simple OOP structures that I have discussed in previous modules in this collection.

While **static** members can be useful in some situations, the existence of **static** members tends to complicate the overall object-oriented structure of Java.

Furthermore, the overuse of **static** members can lead to problems similar to those experienced in languages like C and C++ that support global variables and global functions.

The class named **Class**

I discussed the class named **Class** and how a *conceptual* object of type **Class** exists in memory following a reference to a specific class in the program code.

The **Class** object represents the referenced class in memory, and contains the **static** variables and **static** methods belonging to that class. (*It contains some other information as well, such as the name of the superclass.*)

Class members and instance members

Class variables and *class methods* are declared **static** (*declaring a member **static** in the class definition causes to be called a class member*) .

Instance variables and instance methods are not declared **static** .

Each object has its own copy ...

Every object instantiated from a given class has its own copy of each instance variable declared in the class definition. (*Instance variables are not shared among objects.*)

Every object instantiated from a given class acts like it has its own copy of every instance method declared in the class definition. (*Although instance methods are actually shared among objects in order to reduce the amount of memory required, they are shared in such a way that they don't appear to be shared.*)

Every object shares ...

Every object instantiated from a given class shares the same single copy of each class variable declared in the class definition. Similarly, every object instantiated from a given class shares the same copy of each class method.

Accessing an instance member

An instance variable or an instance method can only be accessed by using a reference to the object that owns it. Even then, it may or may not be accessible depending on the access modifier assigned by the programmer.

Accessing a class member

The single shared copy of a class variable or a class method can be accessed in either of two ways:

- Via a reference to any object instantiated from the class.
- By simply joining the name of the class to the name of the class variable or the class method.

Again, the variable or method may or may not be accessible, depending on the access modifiers assigned by the programmer.

When to use class variables

It is very often appropriate to use **final static** variables, as constants in your programs. It is rarely, if ever, appropriate to use non-final **static** variables in your programs. The use of non-final **static** variables should definitely be minimized.

When to use static methods

It is often appropriate to use **static** methods in your programs, provided there is no requirement for the method to remember anything from one call to the next. **Static** methods should be self-contained.

3.2.12.3 Preview

This module explains how array objects fit into the grand scheme of things in Object-Oriented Programming (OOP) using Java.

A different syntax is required to create array objects than the syntax normally used to create ordinary objects.

Array objects are accessed via references. Any of the methods of the **Object** class can be called on a reference to an array object.

Array objects encapsulate a group of variables. The variables don't have individual names. They are accessed using positive integer index values. The integer indices of a Java array object always extend from **0** to **(n-1)** where **n** is the **length** of the array encapsulated in the object.

All array objects in Java encapsulate one-dimensional arrays. The component type of an array may itself be an array type. This makes it possible to create array objects whose individual components refer to other array objects. This is the mechanism for creating *multi-dimensional* or *ragged* arrays in Java.

3.2.12.4 Discussion and sample code

Three kinds of objects

In an earlier module, I told you that from a conceptual viewpoint, there are at least three kinds of objects involved in a Java program:

- Ordinary objects
- Class objects
- Array objects

Ordinary objects

Most of the discussion up to that point in the collection dealt with what I have referred to in the above list as *ordinary objects*.

These are the objects that you instantiate in your code by applying the **new** operator to a constructor for a class in order to create a new instance (*object*) of that class.

Class objects

In that module that discussed **Class** objects, I emphasized that my discussion of **Class** objects was conceptual in nature and did not necessarily represent an actual implementation. I went on to discuss the class named **Class**, and discussed how the use of that class fits into the grand scheme of OOP in Java. I explained how the existence of *class variables* and *class methods* tends to complicate the rather simple OOP structure consisting only of ordinary objects.

Array objects

I haven't discussed *array objects* up to this point in this collection. That is the purpose of this module.

Also tends to complicate

The existence of array objects also tends to complicate the OOP structure of a Java program consisting only of ordinary objects. Even if you don't consider array objects to be a different kind of object, you must at least consider them to be a *special* kind of object. A completely different syntax is required to create array objects than the syntax normally used to instantiate ordinary objects.

References to array objects

Arrays are objects in Java (*at least, arrays are always encapsulated in objects*). Array objects are dynamically created. Like ordinary objects, array objects are accessed via references. The reference to an array object may be assigned to a reference variable whose type is specified as:

```
TypeName[]
```

For example, Listing 1 (p. 418) shows some unrelated declarations for variables that are capable of storing references to array objects.

Listing 1 . Sample variable declarations for array objects.

```
int[] x1;
Button[] x2;
Object[] x3;
```

Table 3.98

Note the empty square brackets that are required in the variable declarations in Listing 1 (p. 418) .

The special case of type Object

In addition, a reference to an array object may be assigned to a reference variable of type **Object** as shown in Listing 2 (p. 418) , where **x4** is a reference to an array object.

Listing 2 . The special case of type Object.

```
Object x4;
```

Table 3.99

Note that there are *no square brackets* in the statement in Listing 2 (p. 418) .

What does this mean?

This means that like ordinary objects, a reference to an array object *can be treated* as type **Object** (*with no square brackets*).

This further means that any of the methods defined in the **Object** class (*such as the `toString` and `getClass` methods*) can be called on a reference to an array object.

The String representation of an array object's reference

For example, when the `toString` method is called on a reference to an array object containing data of type **int** , the resulting string will be similar to the following:

```
[I@73d6a5
```

Pretty ugly, huh?

You may recognize this as being similar to the default **String** returned by calling the `toString` method on an ordinary object with the name of the class for the ordinary object being replaced by **[I** .

For example, the **String** returned by calling the `toString` method on an object of the class named **Array04** , (*with no overridden `toString` method*), looks something like the following.

```
Array04@73d6a5
```

(*Note that the hexadecimal numeric values following the @ in both of the above examples will change from one case to the next.*)

Calling the getClass method

Similarly, calling the `getClass` method on references to array objects containing data of the types **Array04** , **Button** , and **int** , respectively, and then calling the `toString` method on the **Class** objects returned by the `getClass` method, produces the following:

```

class [LArray04;
class [Ljava.awt.Button;
class [I

```

Complicating the OOP structure

I made the following statement in an earlier paragraph:

"The existence of array objects also tends to complicate the OOP structure of a Java program consisting only of ordinary objects."

Array object is not a subclass of class Object

An array object can be treated as type **Object** for purposes of calling the methods of the **Object** class on the reference to the array object. However, it would probably be misleading to say that an array object is instantiated from a subclass of the **Object** class.

The new operator and the constructor name

Ordinary objects are created by applying the **new** operator to the constructor for a class, where the name of the constructor is always the same as the name of the class. That is not the case with array objects. Array objects are created by applying the **new** operator to the name of the type of data to be encapsulated in the array object.

Passing parameters versus square-bracket notation

In addition, whereas the instantiation of ordinary objects involves parameters passed in parentheses, a square-bracket notation is used instead of parentheses to create an array object. The value in the square brackets specifies the **length** of the array.

Creating an array object

Array objects (*with default initialization values*) are created by applying the **new** operator to the name of the data type to be stored in the array, using a square-bracket notation. An example is shown by the right-hand portion of the first statement in Listing 3 (p. 419) .

Listing 3 . Creating array objects.

```

int[] x1 = new int[5];

int[] x2 = {1,2,3,4,5};

```

Table 3.100

A five-element array object

The first statement in Listing 3 (p. 419) creates an array object capable of storing five values of type **int** . The statement also assigns the array object's reference to the newly-declared reference variable named **x1** .

Default initial values

Each element in the array is initialized to the default value zero.

*(All array elements created in this manner receive a default initial value. Numeric primitive types receive an initial value of zero. Elements of type **boolean** receive an initial value of **false** . Elements whose type is the name of a class or the name of an interface receive an initial value of **null** .)*

Explicit initialization

The second statement in Listing 3 (p. 419) also creates an array object capable of storing five values of type **int** , but in this case, the values in the elements are explicitly initialized to the values shown.

*(Note that the **new** operator is not used in the second statement in Listing 3 (p. 419) . This is also a significant departure from the syntax used to instantiate ordinary objects.)*

This array object's reference is assigned to the reference variable named **x2** .

Note the empty square brackets in the variable declarations

The syntax of the type specification for the reference variable in each statement in Listing 3 (p. 419) is different from the syntax used in the type specification for either a primitive variable or an ordinary class type reference variable (*note the square brackets on the left in Listing 3 (p. 419)*). In Listing 3 (p. 419), the type specifications indicate that each variable is capable of holding a reference to an array object.

The size of the array

Furthermore, the empty square brackets (*in the declaration of the reference variable*) indicate that the reference variable doesn't know (*and doesn't care*) about the size of the array to which it may refer. Each of the reference variables declared in Listing 3 (p. 419) can refer to a one-dimensional array object of any size. Also, each of the reference variables can refer to different array objects at different points in time during the execution of the program.

The Array class As an aside, let me mention that there is a class named **Array**, which provides **static** methods to dynamically create and access Java arrays. The use of the methods of this class makes it possible to handle arrays with a programming style similar to the programming style typically used with ordinary objects. However, the use of the methods of the **Array** class tends to require more programming effort than the square-bracket notation discussed in this module. I will discuss a sample program that illustrates the methods of the **Array** class in a future module.

Encapsulating a group of variables

As is the case with other languages that support arrays, array objects in Java encapsulate a group of variables.

Zero or more variables may be encapsulated in an array object. If the number is zero, the array object is said to be empty.

(An example of an empty array object is the **String[]** array passed to the **main** method in a Java application when the user doesn't enter any arguments at the command line.)

No individual names

Also, as with other languages that support arrays, the variables encapsulated in an array object don't have individual names. Rather, they are referenced using positive integer index values.

(Typically, in Java, the index is placed in square brackets, which are applied to the name of the reference variable holding a reference to the array object.)

Elements or components?

It is common in the literature to refer to the variables that make up an array as its *elements*. However, the Java specification refers to them as *components*. The specification ascribes a different meaning to the word element, as shown in the following quotation from the specification:

"The value of an array component of type **float** is always an element of the **float** value set ...; similarly, the value of an array component of type **double** is always an element of the **double** value set."

Another quotation from Sun (*shown later in this module*) provides a somewhat clearer distinction between the words *component* and *element*.

(However, from force of habit, I will probably use *component* and *element* interchangeably in this module.)

The length of an array

If an array has **n** components, the **length** of the array is **n**. The components of the array are referenced using integer indices from 0 to (n - 1), inclusive.

Another quotation from Sun

Here is another quotation from the Java specification that explains the type specifications for the variable declarations in Listing 1 (p. 418) and Listing 3 (p. 419).

"All the components of an array have the same type, called the component type of the array. If the component type of an array is *T*, then the type of the array itself is written *T[]*."

Components may be of an array type

As of this writing, all array objects in Java encapsulate one-dimensional arrays (*I have read that this may change in the future*).

The component type of an array may itself be an array type. This makes it possible to create array objects whose individual components refer to other array objects.

Multi-dimensional or ragged arrays

One way to think of this is to think of the second level of array objects as being sub-arrays of the original array object. This construct can be used to create multi-dimensional array structures.

(The geometry of such multi-dimensional array structures is not constrained to be rectangles, cubes, etc., as is the requirement in many other languages. Some authors may refer to this as ragged arrays.)

Tree structures

This process of having the components of an array contain references to sub-arrays can be continued indefinitely (*well, maybe not indefinitely, but further than I care to contemplate*).

(This can be thought of as a tree structure where each array object containing references to other array objects is a node in the tree.)

The leaves of the tree

Eventually, the components (*the leaves of the tree structure*) must refer to a component type that is not an array type. According to Sun:

*"... this is called the element type of the original array, and the **components** at this level of the data structure are called the **elements** of the original array."*

Component versus element

Hopefully, the above quotation provides a somewhat clearer distinction between the use of the words *component* and *element* than was presented earlier but then again, maybe not.

Generic references

Any array object's reference can also be assigned to reference variables of the types **Object** , **Cloneable** , or **Serializable** .

*(**Object** is the class at the top of the inheritance hierarchy. **Cloneable** and **Serializable** are interfaces, which are implemented by all array objects. Thus, a reference to an array object can be treated as any of these three types.)*

Generic array objects

Therefore, if the element type of an array object is one of these types, the elements in the array can refer to:

- Other array objects
- Ordinary objects
- A mixture of the two

This is illustrated in the sample program named **Array05** shown in Listing 9 (p. 426) near the end of the module.

Will explain in fragments

I will explain this program in fragments. Listing 4 (p. 421) shows the beginning of the controlling class and the beginning of the **main** method for the program named **Array05** ..

Listing 4 . The beginning of the class named Array05.

```
public class Array05{
    public static void main(String[] args){
        int[] v1 = {1,2,3,4,5};
        Object[] v2 = new Object[2];
```

Table 3.101

Listing 4 (p. 421) creates two array objects.

An array of type `int`

The first array object is a five-element array of element type `int`, with the element values initialized as shown by the values within the curly brackets. The reference to this array object is assigned to the reference variable named `v1`.

An array of element type `Object`

The second array object is a two-element array of element type `Object`, with each of the element values initialized to their default value of `null`. The reference to the array object is assigned to the reference variable named `v2`.

(Note that unlike the previous discussion of `Object`, the declaration of the reference variable in this case does include empty square brackets. I will have more to say about this later.)

A new object of this class

Listing 5 (p. 422) creates a new *ordinary object* of class `Array05`. The code assigns the object's reference to the first element in the array object of element type `Object`, referred to by the reference variable named `v2`.

Listing 5 . A new ordinary object of class `Array05`.

```
v2[0] = new Array05();
```

Table 3.102

This is allowable because the reference to an object of any class can be assigned to a reference variable of type `Object`.

(The array object referred to by `v2` contains two elements, each of which is a reference variable of type `Object`.)

Populate the second element

The code in Listing 6 (p. 422) assigns the reference that points to the existing array object of the element type `int` to the second element in the array object of element type `Object`.

Listing 6 . Populate the second element.

```
v2[1] = v1;
```

Table 3.103

This is allowable because a reference to any array object can be assigned to a reference variable of type `Object`.

Array contains two references

At this point, the array object of element type `Object` contains two references.

(Each of the elements in an array of the declared type `Object[]` is a reference of type `Object`.)

The first element refers to an ordinary object of the class `Array05`.

The second element refers to an array object of type `int`, having five elements, populated with the integer values of 1 through 5 inclusive.

(Note that this is not a multi-dimensional array in the traditional sense. I will discuss the Java approach to such multi-dimensional arrays in the next module. This is simply a generic array of element type **Object**, one element of which happens to contain a reference to an array object of type **int**.)

Print some data

The code in Listing 7 (p. 423) passes each of the references to the **println** method of the **PrintStream** class.

Listing 7 . Print some data.

```
System.out.println(v2[0]);
System.out.println(v2[1]);
```

Table 3.104

The **println** method causes the **toString** method to be called on each reference. The **String** returned by the **toString** method is displayed on the computer screen in each case.

This is allowable because any method defined in the **Object** class (including the **toString** method) can be called on any reference stored in a reference variable of type **Object**.

This is true regardless of whether that reference is a reference to an ordinary object or a reference to an array object.

The output

Listing 7 (p. 423) causes the following two lines of text to be displayed:

```
Array05073d6a5
[I@111f71
```

Pretty ugly, huh?

In both cases, this is the value of the **String** returned by the default version of the **toString** method defined in the **Object** class. Here is what Sun has to say about that default behavior:

*"Returns a string representation of the object. In general, the **toString** method returns a string that textually represents this object. The result should be a concise but informative representation that is easy for a person to read. It is recommended that all subclasses override this method.*

*The **toString** method for class **Object** returns a string consisting of the name of the class of which the object is an instance, the at-sign character '@', and the unsigned hexadecimal representation of the hash code of the object."*

Doesn't address array objects

Obviously, this description of behavior doesn't address the case where the object is an array object, unless the characters **[I** are considered to be the name of a class. (I will have a little more to say about this later.)

Produce some more output

Finally, Listing 8 (p. 423) shows the last statement in this simple program.

Listing 8 . Produce some more output.

    }//end main
} //end class Array05

```

Table 3.105

What does this mean?

As you can see, the syntax of this statement is pretty ugly.

Values are accessed from an array object by following the array's reference with a pair of square brackets containing an integer index value as follows:

```
v2[1]
```

Get the value at index 1 as type Object

This code begins by accessing the component at index value 1 of the array object referred to by the reference variable named `v2`.

The value retrieved is a reference, and is retrieved as type `Object`, (*because the variable named `v2` was declared to be of type `Object[]`*).

A cast is required

A cast is used to convert from type `Object[]` to type `int[]` using the following code:

```
(int[])
```

This produces a reference to an array object capable of containing values of type `int`.

Apply index to the int array

After the type of the reference has been converted, the accessor `[4]` is applied to the reference. This causes the `int` value stored in the array object of type `int` (*at index value 4*) to be returned.

(*If you refer back to Listing 4 (p. 421), you will see that the integer value 5 was stored in the element at index value 4 of this array object.*)

You should try to remember this syntax and compare it with the syntax used in the Java approach to traditional multi-dimensional arrays, which I will discuss in the next module.

The output

Thus, the code in Listing 8 (p. 423) causes the number 5 to be displayed on the computer screen.

Let's recap

To recap, the program named `Array05` creates a two-element array object capable of storing references of type `Object`.

Object is generic

Because `Object` is a completely generic type, each of the elements in the array is capable of storing a reference to any ordinary object, or storing a reference to any array object.

Store reference to ordinary object in generic array

The first element in the array is populated with a reference to an ordinary object instantiated from the class named `Array05`.

(*Important: The actual object does not occupy the array element. Rather, the actual object exists someplace else in memory, and a reference to the object occupies the array element.*)

Store a reference to an array object in the generic array

The second element in the array of element type `Object` is populated with a reference to another array object capable of containing elements of type `int`.

As above, the actual array object of type `int` does not occupy the second element. Rather, that array object exists someplace else in memory, and a reference to the array object occupies the second element in the array of element type `Object`.

Display some data

After the array object of element type **Object** is created and populated, three print statements are executed to display information about the array object and its contents (*those print statements are shown in Listing 7 (p. 423) and Listing 8 (p. 423)*).

The print statements produce the following output on the computer screen:

```
Array05@73d6a5
[Ljava.lang.Object;
5
```

Default textual representation of ordinary object

The first line of output is the default textual representation of the ordinary object, achieved by calling the default **toString** method on the reference to the ordinary object.

Default textual representation of array object

The second line of output is the textual representation of the array object of type **int[]**, achieved by calling the default **toString** method on the reference to the array object.

Primitive value stored in array object

The third line of text is the value stored in element index 4 of the **int[]** array object whose reference is stored in element index 1 of the array object of element type **Object**.

Primitive versus non-primitive array element contents

References to objects are stored in the elements of non-primitive array objects. The objects themselves exist somewhere else in memory.

Actual primitive values are stored in the elements of a primitive array object.

Thus, the elements of an array object contain actual primitive values, null references, or actual references to ordinary or array objects, depending on the type of the elements of the array object.

3.2.12.5 Summary

This module begins the discussion of array objects in Java.

The existence of array objects tends to complicate the OOP structure of a Java program otherwise consisting only of ordinary objects.

A completely different syntax is required to create array objects than the syntax normally used to instantiate ordinary objects. Ordinary objects are normally instantiated by applying the **new** operator to the constructor for the target class passing parameters between a pair of matching parentheses.

Array objects (*with default initialization*) are created using the **new** operator, the type of data to be encapsulated in the array, and a square-bracket notation to specify the **length** of the array encapsulated in the object.

Array objects with explicit initialization are created using a comma-separated list of expressions enclosed in curly brackets.

Arrays in Java are objects, which are dynamically created and allocated to dynamic memory.

Like ordinary objects, array objects are accessed via references. The type of such a reference is considered to be **TypeName[]** (*note the empty square brackets in the type specification*).

A reference to an array object can also be assigned to a reference variable of type **Object** (*note the absence of square brackets*). Thus, any of the methods of the **Object** class can be called on a reference to an array object.

As is the case with other languages that support arrays, array objects in Java encapsulate a group of zero or more variables. The variables encapsulated in an array object don't have individual names. Rather, they are accessed using positive integer index values.

The integer indices of a Java array object always extend from **0** to **(n-1)** where **n** is the **length** of the array object.

As of the time of this writing, all array objects in Java encapsulate one-dimensional arrays. However, the component type of an array may itself be an array type. This makes it possible to create array objects whose individual components refer to other array objects. This is the mechanism for creating *multi-dimensional* or *ragged* arrays in Java.

The reference to any array object can be assigned to reference variables of the types **Object** , **Cloneable** , or **Serializable** . If the element type of an array object is one of these types, the elements in the array can refer to:

- Other array objects
- Ordinary objects
- A mixture of the two

3.2.13.3 Preview

This module explains various details regarding the use of array objects in Java, and illustrates many of those details through the use of sample code.

A sample program shows you three ways to emulate traditional two-dimensional rectangular arrays, and also shows you how to create and use ragged arrays.

3.2.13.4 Discussion and sample code

Array objects

A different syntax is required to create array objects than the syntax normally used to create ordinary objects.

Array objects are accessed via references.

Any of the methods of the `Object` class can be called on a reference to an array object.

The indices of a Java array object

Array objects encapsulate a group of variables, which don't have individual names. They are accessed using positive integer index values. The integer indices of a Java array object always extend from `0` to `(n-1)` where `n` is the **length** of the array encapsulated in the object.

Multidimensional arrays

Array objects in Java encapsulate one-dimensional arrays. However, the component type of an array may itself be an array type. This makes it possible to create array objects whose individual components refer to other array objects. This is the mechanism for creating *multi-dimensional* or *ragged* arrays in Java.

Such a structure of array objects can be thought of as a tree of array objects, with the data being stored in the array objects that make up the leaves of the tree.

Array types

When declaring a reference variable capable of referring to an array object, the array type is declared by writing the name of an element type followed by some number of empty pairs of square brackets `[]`. This is illustrated in Listing 1 (p. 429), which declares a reference variable named `v1`, capable of storing a reference to a *two-dimensional* array of type `int`.

Listing 1 . Reference variable declaration.

```
int[][] v1;
```

Table 3.107

(Note that Listing 1 (p. 429) doesn't really declare a two-dimensional array in the traditional sense of other programming languages. Rather, it declares a reference variable capable of storing a reference to a one-dimensional array object, which in turn is capable of storing references to one-dimensional array objects of type `int`.)

Multiple pairs of square brackets are allowed

The components in an array object may refer to other array objects. The number of bracket pairs used in the declaration of the reference variable indicates the depth of array nesting (*in the sense that array elements can refer to other array objects*). This is one of the ways that Java implements the concept of traditional multi-dimensional arrays (*I will show you some other ways later in this module*).

The code in Listing 1 (p. 429) shows two levels of nesting for the reference variable of type

```
int[][]
```

Length not part of variable declaration

Note that an array's length is not part of its type or reference variable declaration.

Ragged arrays

Note also that multi-dimensional arrays, when implemented in this fashion, are not required to represent rectangles, cubes, etc. For example, the number of elements in each row of a Java two-dimensional array can be different. Some authors refer to this as a *ragged array*.

Allowable types

The specified element type of an array may be any primitive or reference type. Note, however, that all elements of the array must be of the same type (*consistent with the type-conversion rules discussed below*).

Listing 2 (p. 430) shows the declaration of a reference variable capable of referring to a three-dimensional array object of element type **Button** (*Button is one of the classes in the standard class library*).

Listing 2 . A three-dimensional array object of element type Button.
<pre>Button[][][] v2;</pre>

Table 3.108

Rules of type conversion and assignment compatibility apply

The normal rules of *type conversion* and *assignment compatibility* apply when creating and populating array objects. For example, if the specified type is the name of a non-abstract class, a null reference or a reference to any object instantiated from that class or any subclass of that class may be stored in the array element.

The generic class Object

For example, Listing 3 (p. 430) shows the declaration of a reference variable capable of referring to a one-dimensional array object of element type **Object**.

Since **Object** is the superclass of all other classes, this array object is capable of storing references to objects instantiated from any other class. (*As we saw in the previous module, it is also capable of storing a reference to any other array object as well.*)

Listing 3 . The generic class Object.
<pre>Object[] v3;</pre>

Table 3.109

Primitive type conversions

Similarly, if the declared element type for the array object is one of the primitive types, the elements of the array can be used to store values of any primitive type that is *assignment compatible* with the declared type (*without the requirement for a cast*).

For example, the code in Listing 4 (p. 431) shows the creation of a one-dimensional array object capable of storing values of type **int**. The array object has a length of 3 elements, and the object's reference is stored in a reference variable named **v1**.

Listing 4 . Primitive type conversions.

```

int[] v1;
v1 = new int[3];
byte x1 = 127;
short x2 = 16384;
int x3 = 32000;
v1[0] = x1;
v1[1] = x2;
v1[2] = x3;

```

Table 3.110**Assignment-compatible assignments**

Values of the types **byte** , **short** , and **int** , are stored in the elements of the array object in Listing 4 (p. 431) .

Actual type is lost in the process

It should be noted that the **byte** and **short** values are converted to type **int** as they are stored. When retrieved later, they will be retrieved as type **int** . Any indication that these values were ever of any type other than **int** is lost in the process of storing and retrieving the values.

What about class types?

If the declared element type is the name of a class, (*which may or may not be abstract*), a null reference or a reference to any object instantiated from the class or any subclass of the class may be stored in the array element.

(*Obviously you can't store a reference to an object instantiated from an abstract class, because you can't instantiate an abstract class.*)

What about an interface type?

If the declared element type is an interface type, a null reference or a reference to any object instantiated from any class that implements the interface can be stored in the array element.

(*This is an extremely powerful concept, allowing references to objects instantiated from many different classes to be collected into an array as the interface type.*)

Array reference variables

All array objects are accessed via references. A reference variable whose declared type is an array type *does not contain an array*. Rather, it contains either null, or a reference to an array object.

Allocation of memory

Declaring the reference variable does not create an array, nor does it allocate any space for the array components. It simply causes memory to be allocated for the reference variable itself, which may later contain a reference to an array object.

Initialization

In the same sense that it is possible to declare a reference variable for an ordinary object, and initialize it with a reference to an object when it is declared, it is also possible to declare a reference to an array object and initialize it with a reference to an array object when it is declared. This is illustrated in Listing 5 (p. 432) , which shows the following operations combined into a single statement:

- Declaration of a variable to contain a reference to an array object
- Creation of the array object
- Storage of the array object's reference in the reference variable

Listing 5 . Initialization.

```
int[] v1 = new int[3];
```

Table 3.111**Can refer to different array objects**

The **length** of an array is not established when the reference variable is declared. As with references to ordinary objects, a reference to an array object can refer to different array objects at different points in the execution of a program.

For example, a reference variable that is capable of referring to an array of type **int[]** can refer to an array object of a given **length** at one point in the program and can refer to a different array object of the same type but a different **length** later in the program.

Placement of square brackets

When declaring an array reference variable, the square brackets **[]** may appear as part of the type, or following the variable name, or both. This is illustrated in Listing 6 (p. 432) .

Listing 6 . Placement of square brackets.

```
int[][] v1;
int[] v2[];
int v3[][];
```

Table 3.112**Type and length**

Once an array object is created, its type and length never changes. A reference to a different array object must be assigned to the reference variable to cause the reference variable to refer to an array of different length.

Creating the actual array object

An array object is created by an array creation expression or an array initializer.

An array creation expression (*or an array initializer*) specifies:

- The element type
- The number of levels of nested arrays
- The length of the array for at least one of the levels of nesting

Two valid array creation expressions are illustrated by the statements in Listing 7 (p. 432) .

Listing 7 . Creating the actual array object.

continued on next page

```

int[][] v1;
int[] v2[];

v1 = new int[2][3];
v2 = new int[10][];

```

Table 3.113

A two-dimensional rectangular array

The third statement in Listing 7 (p. 432) creates an array object of element type `int` with two levels of nesting. This array object can be thought of as a traditional two-dimensional rectangular array having two rows and three columns. (*This is a somewhat arbitrary choice as to which dimension specifies the number of rows and which dimension specifies the number of columns. You may prefer to reverse the two.*)

A ragged array

The fourth statement also creates an array object of element type `int` with two levels of nesting. However, the number of elements in each column is not specified at this point, and it is not appropriate to think of this as a two-dimensional rectangular array. In fact, once the number of elements in each column has been specified, it may not describe a rectangle at all. Some authors refer to an array of this type as a *ragged array*.

The length of the array

The **length** of the array is always available as a **final** instance variable named **length**. I will show you how to use the value of **length** in a sample program later in this module.

Accessing array elements

An array element is accessed by an *array access expression*. The access expression consists of an expression whose value is an array reference followed by an indexing expression enclosed by matching square brackets.

The expression in parentheses in Listing 8 (p. 433) illustrates an array access expression (*or perhaps two concatenated array access expressions*).

Listing 8 . An array access expression.

```

int[][] v1 = new int[2][3];
System.out.println(v1[0][1]);

```

Table 3.114

First-level access

This *array access expression* first accesses the contents of the element at index 0 in the array object referred to by the reference variable named `v1`. This element contains a reference to a second array object (*note the double matching square brackets, `[[]]` in the declaration of the variable named `v1`*).

Second-level access

The *array access expression* in Listing 8 (p. 433) uses that reference to access the value stored in the element at index value 1 in the second array object. That value is then passed to the `println` method for display on the standard output device.

(*In this case, the value 0 is displayed, because array elements are automatically initialized to default values when the array object is created. The default value for all primitive numeric values is zero.*)

Zero-based indexing

All array indexes in Java begin with **0** . An array with length **n** can be indexed by the integers **0** to **(n-1)** . Array accesses are checked at runtime. If an attempt is made to access the array with any other index value, an **ArrayIndexOutOfBoundsException** will be thrown.

Index value types

Arrays must be indexed by integer values of the following types: **int** , **short** , **byte** , or **char** . For any of these types other than **int** , the value will be promoted to an **int** and used as the index.

An array cannot be accessed using an index of type **long** . Attempting to do so results in a compiler error.

Default initialization

If the elements in an array are not purposely initialized when the array is created, the array elements will be automatically initialized with default values. The default values are:

- All reference types: null
- Primitive numeric types: 0
- Primitive boolean type: false
- Primitive char type: the Unicode character with 16 zero-valued bits

Explicit initialization of array elements

The values in the array elements may be purposely initialized when the array object is created using a comma-separated list of expressions enclosed by matching curly brackets. This is illustrated in Listing 9 (p. 434) .

Listing 9 . Explicit initialization of array elements.

```
int[] v1 = {1,2,3,4,5};
```

Table 3.115

No new operator

Note that this format does not use the **new** operator. Also note that the expressions in the list may be much more complex than the simple literal values shown in Listing 9 (p. 434) .

Length and order

When this format is used, the length of the constructed array will equal the number of expressions in the list.

The expressions in an array initializer are executed from left to right in the order that they occur in the source code. The first expression specifies the value at index value zero, and the last expression specifies the value at index value $n-1$ (*where n is the length of the array*).

Each expression must be assignment-compatible with the array's component type, or a compiler error will occur.

A sample program

The previous paragraphs in this module have explained some of the rules and characteristics regarding array objects. They have also illustrated some of the syntax involved in the use of array objects in Java.

More powerful and complex

Many aspiring Java programmers find the use of array objects to be something less than straightforward, and that is understandable. In fact, Java array objects are somewhat more powerful than array structures in many other programming languages, and this power often manifests itself in additional complexity.

A traditional two-dimensional rectangular array

Some of that complexity is illustrated by the program named **Array07** , shown in Listing 26 (p. 449) near the end of this module. This program illustrates three different ways to accomplish essentially the same

task using array objects in Java. That task is to emulate a traditional two-dimensional rectangular array as found in other programming languages. Two of the ways that are illustrated are essentially ragged arrays with sub-arrays having equal length.

Ragged arrays

The program also illustrates two different ways to work with array objects and ragged arrays.

Will discuss in fragments

As is my practice, I will discuss and explain the program in fragments.

All of the interesting code in this program is contained in the **main** method, so I will begin my discussion with the first statement in the **main** method.

Create a two-dimensional rectangular array structure

Listing 10 (p. 435) creates an array structure that emulates a traditional rectangular array with two rows and three columns.

Listing 10 . Create a two-dimensional rectangular array structure.
<pre>Object[][] v1 = new Object[2][3];</pre>

Table 3.116

(Note that unlike the ragged array structures to be discussed later, this approach requires all rows to be the same length and all columns to be the same length.)

Reference variable declaration

The code to the left of the equal sign (=) in Listing 10 (p. 435) declares a reference variable named **v1** . This reference variable is capable of holding a reference to an array object whose elements are of the type **Object[]** .

In other words, this reference variable is capable of

- holding a reference to an array object,
- whose elements are capable of holding references to other array objects,
- whose elements are of type **Object** .

Two levels of nesting

The existence of double matching square brackets in the variable declaration in Listing 10 (p. 435) indicates two levels of nesting.

Restrictions

The elements in the array object referred to by **v1** can only hold references to other array objects whose element type is **Object** (or references to array objects whose element type is a subclass of **Object**).

The elements in the array object referred to by **v1** cannot hold references to ordinary objects instantiated from classes, or array objects whose element type is a primitive type.

In other words, the elements in the array object referred to by **v1** can only hold references to other array objects. The element types of those array objects must be *assignment compatible* with the type **Object** (this includes interface types and class types but not primitive types).

A tree of empty array objects

The code to the right of the equal sign (=) in Listing 10 (p. 435) creates a *tree structure* of array objects. The object at the root of the tree is an array object of type **Object[]** , having two elements (a *length* of two).

The reference variable named **v1** refers to the array object that forms the root of the tree.

Each of the two elements in the root array object is initialized with a reference to another array object.

(These two objects might be viewed as sub-arrays, or as child nodes in the tree structure).

Each of the child nodes is an array object of type **Object** , and has a **length** of three.

Each element in each of the two child node array objects is initialized to the value **null** (*this is the default initialization for array elements of reference types that don't yet refer to an object*).

Recap

To recap, the reference variable named **v1** contains a reference to a two-element, one-dimensional array object. Each element in that array object is capable of storing a reference of type **Object[]** (a reference to another one-dimensional array object of type **Object**).

Two sub-array objects

Two such one-dimensional sub-array (or child node) objects, of element type **Object** , are created. References to the two sub-array objects are stored in the elements of the two-element array object at the root of the tree.

Each of the sub-array objects has three elements. Each element is capable of storing a reference to an object as type **Object** .

The leaves of the tree

These two sub-array objects might be viewed as the leaves of the tree structure.

Initialize elements to null

However, the objects of type **Object** don't exist yet. Therefore, each element in each of the sub-array objects is automatically initialized to **null** .

Arrays versus sub-arrays

Note that there is no essential difference between an array object and a sub-array object in the above discussion. The use of the sub prefix is used to indicate that an ordinary array object belongs to another array object, because the reference to the sub-array object is stored in an element of the owner object.

Many dimensions are possible

Multi-dimensional arrays of any (reasonable) depth can be emulated in this manner. An array object may contain references to other array objects, which may contain references to other array objects, and so on.

The leaves of the tree structure

Eventually, however, the elements of the leaves in the tree structure must be specified to contain either primitive values or references to ordinary objects. This is where the data is actually stored.

(Note however, that if the leaves are specified to contain references of type **Object** , they may contain references to other array objects of any type, and the actual data could be stored in those array objects.)

The length of an array

Every array object contains a public **final** instance variable named **length** , which contains an integer value specifying the number of elements in the array.

Once created, the length of the array encapsulated in an array object cannot change. Therefore, the value of **length** specifies the length of the array throughout the lifetime of the array object.

Using length to populate the leaves of the tree structure

The value of **length** is very handy when processing array objects. This is illustrated in Listing 11 (p. 436) , which uses a nested **for** loop to populate the elements in the leaves of the tree structure referred to by **v1** . (The elements in the leaf objects are populated with references to objects of type **Integer** . Note that **Integer** is not a primitive type. Instead, it is a wrapper class for primitive data of type **int** .)

Listing 11 . Using length to populate the leaves of the tree structure.

```

for(int i=0;i<v1.length;i++){
  for(int j=0;j<v1[i].length;j++){
    v1[i][j] =
      new Integer((i+1)*(j+1));
  }//end inner loop
} //end outer loop

```

Table 3.117**Using length in loop's conditional expressions**

Hopefully by now you can read and understand this code without a lot of help from me. I will point out, however, that the value returned by `v1.length` (in the conditional expression for the outer loop) is the number of leaves in the tree structure (this tree structure has two leaves).

I will also point out that the value returned by `v1[i].length` (in the conditional expression for the inner loop) is the number of elements in each leaf array object (each leaf object in this tree structure has three elements).

Finally, I will point out that the expression `v1[i][j]` accesses the *j*th element in the *i*th leaf, or sub-array. In the traditional sense of a rectangular array, this could be thought of as the *j*th column of the *i*th row. This mechanism is used to store object references in each element of each of the leaf array objects.

Populate with references to Integer objects

Thus, each element in each leaf array object is populated with a reference to an object of the type `Integer`. Each object of the type `Integer` encapsulates an `int` value calculated from the current values of the two loop counters.

Display leaf object contents

In a similar manner, the code in Listing 12 (p. 437) uses the `length` values in the conditional expressions of nested `for` loops to access the references stored in the elements of the leaf array objects, and to use those references to access and display the values encapsulated in the `Integer` objects whose references are stored in those elements.

Listing 12 . Display leaf object contents.

```

for(int i=0;i<v1.length;i++){
  for(int j=0;j<v1[i].length;j++){
    System.out.print(
      v1[i][j] + " ");
  }//end inner loop
  System.out.println();//new line
} //end outer loop

```

Table 3.118**The rectangular output**

The code in Listing 12 (p. 437) produces the following output on the screen.

```

1 2 3
2 4 6

```

As you can see, this emulates a traditional two-dimensional array having two rows and three columns.

A ragged array with two rows and three columns

The second approach to emulating a traditional two-dimensional rectangular array will create a *ragged array* where each row is the same length.

(It is very important to note that, unlike this case, with a ragged array, the number of elements in each row or the number of elements in each column can be different.)

The most significant thing about this approach is the manner in which the tree of array objects is created (see Listing 13 (p. 438)).

Listing 13 . Beginning of a ragged array with two rows and three columns.

```
Object[][] v2 = new Object[2][];
```

Table 3.119

Three statements required

With this approach, three statements are required to replace one statement from the previous approach. *(Two additional statements are shown in Listing 14 (p. 438) .)*

A single statement in the previous approach (Listing 10 (p. 435)) created all three array objects required to construct the tree of array objects, and initialized the elements in the leaf array objects with **null** values.

Create only the root array object

However, the code in Listing 13 (p. 438) creates only the array object at the root of the tree. That array object is an array object having two elements capable of storing references of type **Object[]** .

Empty square brackets

If you compare this statement with the statement in Listing 10 (p. 435) , you will notice that the right-most pair of square brackets in Listing 13 (p. 438) is empty. Thus, Listing 13 (p. 438) creates only the array object at the root of the tree, and initializes the elements in that array object with **null** values.

Leaf array objects don't exist yet

The leaf array objects don't exist at the completion of execution of the statement in Listing 13 (p. 438) .

Create the leaf array objects

The statements in Listing 14 (p. 438) create two array objects of element type **Object** .

Listing 14 . Create the leaf array objects.

```
v2[0] = new Object[3];
v2[1] = new Object[3];
```

Table 3.120

Save the references to the leaves

References to these two leaf objects are stored in the elements of the array object at the root of the tree, *(which was created in Listing 13 (p. 438))*. Thus, these two array objects become the leaves of the tree structure of array objects.

This completes the construction of the tree structure. Each element in each leaf object is initialized with **null** .

Why bother?

You might ask why I would bother to use this approach, which requires three statements in place of only one statement in the previous approach.

The answer is that I wouldn't normally use this approach if my objective is to emulate a traditional rectangular array. However, this approach is somewhat more powerful than the previous approach.

The lengths of the leaf objects can differ

With this approach, the **length** values of the two leaf array objects need not be the same. Although I caused the **length** value of the leaf objects to be the same in this case, I could just as easily have caused them to be different lengths (*I will illustrate this capability later in the program*).

Populate and display the data

If you examine the complete program in Listing 26 (p. 449) near the end of the module, you will see that nested **for** loops, along with the value of **length** was used to populate and display the contents of the leaf array objects. Since that portion of the code is the same as with the previous approach, I won't show and discuss it here.

The rectangular output

This approach produced the following output on the screen, (*which is the same as before*):

```
1 2 3
2 4 6
```

Now for something really different

The next approach that I am going to show you for emulating a two-dimensional rectangular array is significantly different from either of the previous two approaches.

Not element type **Object[]**

In this approach, I will create a one-dimensional array object of element type **Object** (*not element type **Object[]***) . I will populate the elements of that array object with references to other array objects of element type **Object** . In doing so, I will create a tree structure similar to those discussed above.

The length of the leaf objects

As with the second approach above, the array objects that make up the leaves of the tree can be any length, but I will make them the same length in order to emulate a traditional rectangular two-dimensional array.

Create the array object

First consider the statement shown in Listing 15 (p. 439) . Compare this statement with the statements shown earlier in Listing 10 (p. 435) and Listing 13 (p. 438) .

Listing 15 . Create the array object.
<pre>Object[] v3 = new Object[2];</pre>

Table 3.121

No double square brackets

Note in particular that the statement in Listing 15 (p. 439) does not make use of double square brackets, as was the case in Listing 10 (p. 435) and Listing 13 (p. 438) . Thus, the statement show in Listing 15 (p. 439) is entirely different from the statements shown in Listing 10 (p. 435) and Listing 13 (p. 438) .

Declare a reference variable

That portion of the statement to the left of the equal sign (=) declares a reference variable capable of storing a reference to an array object whose elements are capable of storing references of the type **Object** (not type **Object[]** as in the previous examples).

Refer to the root object

This reference variable will refer to an array object that forms the root of the tree structure. However, the root object in this case will be considerably different from the root objects in the previous two cases.

In the previous two cases, the elements of the root object were required to store references of type **Object[]** (note the square brackets). In other words, an array object whose elements are of type **Object[]** can only store references to other array objects whose elements are of type **Object**.

A more general approach

However, an array object whose elements are of type **Object** (as is the case here), can store:

- References to any object instantiated from any class
- References to array objects whose elements are of any type (primitive or reference)
- A mixture of the two kinds of references .

Therefore, this is a much more general, and much more powerful approach.

A price to pay

However, there is a price to pay for the increased generality and power. In particular, the programmer who uses this approach must have a much better understanding of Java object-oriented programming concepts than the programmer who uses the two approaches discussed earlier in this module.

Particularly true relative to first approach

This is particularly true relative to the first approach discussed earlier. That approach is sufficiently similar to the use of multi-dimensional arrays in other languages that a programmer with little understanding of Java object-oriented programming concepts can probably muddle through the syntax based on prior knowledge. However, it is unlikely that a programmer could muddle through this approach without really understanding what she is doing.

Won't illustrate true power

Although this approach is very general and very powerful, this sample program won't attempt to illustrate that power and generality. Rather, this sample program will use this approach to emulate a traditional two-dimensional rectangular array just like the first two approaches discussed earlier. (Later, I will also use this approach for a couple of ragged arrays.)

Populate the root object

The two statements in Listing 16 (p. 440) create two array objects, each having three elements. Each element is capable of storing a reference to any object that is *assignment compatible* with the **Object** type.

(Assignment compatibility includes a reference to any object instantiated from any class, or a reference to any array object of any type (including primitive types), or a mixture of the two.)

Listing 16 . Populate the root object.
<pre style="margin: 0;">v3[0] = new Object[3]; v3[1] = new Object[3];</pre>

Table 3.122

References to the two new array objects are stored in the elements of the array object that forms the root of the tree structure. The two new array objects form the leaves of the tree structure.

Populate the leaf array objects

As in the previous two cases, the code in Listing 17 (p. 440) uses nested **for** loops to populate the array elements in the leaf objects with references to new **Integer** objects. (The **Integer** objects encapsulate **int** values based on the loop counter values for the outer and inner loops.)

Listing 17 . Populate the leaf array objects.

```
for(int i=0;i<v3.length;i++){
  for(int j=0;j<((Object[])v3[i]).length;j++){
    ((Object[])v3[i])[j] = new Integer((i+1)*(j+1));
  }//end inner loop
};//end outer loop
```

Table 3.123

Added complexity

The added complexity of this approach manifests itself in

- The *cast operators* shown in Listing 17 (p. 440)
- The attendant required grouping of terms within parentheses

Inside and outside the parentheses

Note that within the inner loop, one of the square-bracket accessor expressions is inside the parentheses and the other is outside the parentheses.

Why are the casts necessary?

The casts are necessary to convert the references retrieved from the array elements from type **Object** to type **Object[]** . For example, the reference stored in **v3[i]** is stored as type **Object** .

Get length of leaf array object

The cast in the following expression converts that reference to type **Object[]** before attempting to get the value of **length** belonging to the array object whose reference is stored there.

```
((Object[])v3[i]).length
```

Assign a value to an element in the leaf array object

Similarly, the following expression converts the reference stored in **v3[i]** from type **Object** to type **Object[]** . Having made the conversion, it then accesses the **jth** element of the array object whose reference is stored there (*in order to assign a value to that element*).

```
((Object[])v3[i])[j]=
```

Display data in leaf array objects

Listing 18 (p. 441) uses similar casts to get and display the values encapsulated in the **Integer** objects whose references are stored in the elements of the leaf array objects.

Listing 18 . Display data in leaf array objects.

```

    for(int i=0;i<v3.length;i++){
    for(int j=0;j<((Object[])v3[i]).length;j++){
        System.out.print(((Object[])v3[i])[j] + " ");
    }//end inner loop
    System.out.println();//new line
} //end outer loop

```

Table 3.124**The rectangular output**

This approach produced the following output on the screen, (*which is the same as the previous two approaches*):

```

  1 2 3
  2 4 6

```

Ragged arrays

All the code in the previous three cases has been used to emulate a traditional rectangular two-dimensional array. In the first case, each row was required to have the same number of elements by the syntax used to create the tree of array objects.

In the second and third cases, each row was not required to have the same number of elements, but they were programmed to have the same number of elements in order to emulate a rectangular two-dimensional array.

A triangular array, sort of ...

Now I am going to show you some cases that take advantage of the *ragged-array* capability of Java array objects. In the next case, (*beginning with Listing 19 (p. 442)*), I will create a ragged array having two rows. The first row will have two elements and the second row will have three elements. (*This array object might be thought of as being sort of triangular.*)

Listing 19 . A triangular array.

```

Object[][] v4 = new Object[2][];
v4[0] = new Object[2];
v4[1] = new Object[3];

```

Table 3.125**You have seen this before**

You saw code like this in the second case discussed earlier. However, in that case, the second and third statements created new array objects having the same length. In this case, the second and third statements create array objects having different lengths. This is one of the ways to create a ragged array in Java (*you will see another way in the next case that I will discuss*).

Populate the leaf array objects

Listing 20 (p. 442) populates the elements of the leaf array objects with references to objects of the class **Integer** .

Listing 20 . Populate the leaf array objects.

```

    for(int i=0;i<v4.length;i++){
    for(int j=0;j<v4[i].length;j++){
        v4[i][j] =
            new Integer((i+1)*(j+1));
    }//end inner loop
    }//end outer loop

```

Table 3.126**You have seen this before also**

You have also seen the code in Listing 20 (p. 442) before. I repeated it here because this case clearly emphasizes the value of the **length** constant that is available in all Java array objects. In the earlier case, the **length** of the two leaf array objects was the same, so it would have been feasible to simply hard-code that value into the conditional expression of the inner **for** loop.

The length is not the same now

However, in this case, the **length** of the two leaf array objects is not the same. Therefore, it wouldn't work to hard-code a limit into the conditional expression of the inner **for** loop. However, because the **length** of each leaf array object is available as a public member of the array object, that value can be used to control the number of iterations of the inner loop for each separate leaf array object.

The triangular output

The next section of code in the program shown in Listing 26 (p. 449) near the end of the module uses the same code as before to display the **int** values encapsulated in the **Integer** objects whose references are stored in the leaf array objects. Since it is the same code as before, I won't repeat it here.

The output produced by this case is shown below:

```

1 2
2 4 6

```

Note that this is not the same as before, and this output does not describe a rectangular array. Rather, it describes a ragged array where the rows are of different lengths.

(As I indicated earlier, it is sort of triangular. However, it could be any shape that you might want it to be.)

A more general approach

The next case, shown in Listing 21 (p. 443) , is the same as the third case discussed earlier, except that the lengths of the leaf array objects are not the same.

As before, this case creates a one-dimensional array object of type **Object** (*having two elements*) that forms the root of a tree. Each element in the root object contains a reference to another array object of type **Object** .

One of those leaf objects has two elements and the other has three elements, thus producing a ragged array (*you could make the lengths of those objects anything that you want them to be*).

Listing 21 . A more general approach.

```

Object[] v5 = new Object[2];
v5[0] = new Object[2];
v5[1] = new Object[3];

```

Table 3.127**Populate the leaf objects**

As before, the elements in the leaf array objects are populated with references to objects of the class **Integer** , which encapsulate **int** values based on the current value of the loop counters. This is shown in Listing 22 (p. 444) .

Listing 22 . Populate the leaf objects.

```

    for(int i=0;i<v5.length;i++){
    for(int j=0;
        j<((Object[])v5[i]).length;
            j++){
        ((Object[])v5[i])[j] =
            new Integer((i+1)*(j+1));
    }//end inner loop
    }//end outer loop

```

Table 3.128**Same code as before**

This is the same code that you saw in Listing 17 (p. 440) . I repeated it here to emphasize the requirement for casting .

Display the data

This case uses the same code as Listing 18 (p. 441) to display the **int** values encapsulated by the **Integer** objects whose references are stored in the elements of the leaf array objects. I won't repeat that code here.

The triangular output

The output produced by this case is shown below:

```

    1 2
  2 4 6

```

Note that this is the same as the case immediately prior to this one. Again, it does not describe a rectangular array. Rather, it describes a ragged array where the rows are of different lengths.

A more general case

I'm going to show you one more general case for a ragged array. This case illustrates a more general approach. In this case, I will create a one-dimensional array object of element type **Object** . I will populate the elements of that array object with references to other array objects. These array objects will be the leaves of the tree.

Leaf array objects are type int

In this case, the leaves won't be of element type **Object** . Rather, the elements in the leaf objects will be designed to store primitive **int** values.

(An even more general case would be to populate the elements of the root object with references to a mixture of objects of class types, interface types, and array objects where the elements of the array objects are designed to store primitives of different types, and references of different types. Note, however, each leaf array object must be designed to store a single type, but will accept for storage any type that is assignment-compatible with the specified type for the array object.)

This case begins in Listing 23 (p. 446) , which creates the root array object, and populates its elements with references to leaf array objects of type **int** .

Listing 23 . Beginning of a more general case .

```
Object[] v6 = new Object[2];
v6[0] = new int[7];
v6[1] = new int[3];
```

Table 3.129**Leaf objects are different lengths**

One of the leaf array objects has a length of 7. The other has a length of 3.

Populate the leaf array elements

Listing 24 (p. 446) populates the elements in the leaf array objects with values of type **int** .

Listing 24 . Populate the leaf array elements.

```
for(int i=0;i<v6.length;i++){
for(int j=0;j<((int[])v6[i]).length;j++){
((int[])v6[i])[j] = (i+2)*(j+2);
} //end inner loop
} //end outer loop
```

Table 3.130**Similar to previous code**

The code in Listing 24 (p. 446) is similar to code that you saw earlier. The differences are:

- Cast is to type **int[]** instead of **object[]**
- Values assigned are type **int** instead of references to **Integer** objects

Display the output

Finally, Listing 25 (p. 446) displays the **int** values stored in the elements of the leaf array objects.

Listing 25 . Display the output.

```
for(int i=0;i<v6.length;i++){
for(int j=0;j<((int[])v6[i]).length;j++){
System.out.print(((int[])v6[i])[j] + " ");
} //end inner loop
System.out.println();//new line
} //end outer loop
```

Table 3.131

The code in Listing 25 (p. 446) is very similar to what you have seen before, and there should be no requirement for an explanation of this code.

The code in Listing 25 (p. 446) produces the following output:

```
4 6 8 10 12 14 16
6 9 12
```

I will leave it as an exercise for the student to correlate the output with the code.

3.2.13.5 Summary

When declaring a reference variable capable of referring to an array object, the array type is declared by writing the name of an element type followed by some number of empty pairs of square brackets [].

The components in an array object may refer to other array objects. The number of bracket pairs used in the declaration of the reference variable indicates the depth of array nesting (*in the sense that array elements can refer to other array objects*).

An array's length is not part of its type or reference variable declaration.

Multi-dimensional arrays are not required to represent rectangles, cubes, etc. They can be *ragged*.

The normal rules of *type conversion* and *assignment compatibility* apply when creating and populating array objects.

Object is the superclass of all other classes. Therefore, an array of element type **Object** is capable of storing references to objects instantiated from any other class. The type declaration for such an array object would be **Object[]**.

An array of element type **Object** is also capable of storing references to any other array object.

If the declared element type for the array object is one of the primitive types, the elements of the array can be used to store values of any primitive type that is *assignment compatible* with the declared type (*without the requirement for a cast*).

If the declared element type is the name of a class, (*which may or may not be abstract*), a null reference or a reference to any object instantiated from the class or any subclass of the class may be stored in the array element.

If the declared element type is an interface type, a null reference or a reference to any object instantiated from any class that implements the interface can be stored in the array element.

A reference variable whose declared type is an array type *does not contain an array*. Rather, it contains either null, or a reference to an array object. Declaring the reference variable does not create an array, nor does it allocate any space for the array components.

It is possible to declare a reference to an array object and initialize it with a reference to an array object when it is declared.

A reference to an array object can refer to different array objects (*of the same element type and different lengths*) at different points in the execution of a program.

When declaring an array reference variable, the square brackets [] may appear as part of the type, or following the variable name, or both.

Once an array object is created, its type and length never changes.

An array object is created by an array creation expression or an array initializer.

An array creation expression (*or an array initializer*) specifies:

- The element type
- The number of levels of nested arrays
- The length of the array for at least one of the levels of nesting

The length of the array is always available as a final instance variable named **length**.

An array element is accessed by an expression whose value is an array reference followed by an indexing expression enclosed by matching square brackets.

If an attempt is made to access the array with an invalid index value, an **ArrayIndexOutOfBoundsException** will be thrown.

Arrays must be indexed by integer values of the types **int** , **short** , **byte** , or **char** . An array cannot be accessed using an index of type **long** .

If the elements in an array are not purposely initialized when the array is created, the array elements will be automatically initialized with default values.

The values in the array elements may be purposely initialized when the array object is created using a comma-separated list of expressions enclosed by matching curly brackets.

The program in this module illustrated three different ways to emulate traditional rectangular two-dimensional arrays.

The program also illustrated two different ways to create and work with ragged arrays.

3.2.13.6 What's next?

In the next module, I will provide so additional information about array objects, and then illustrate the use of the classes named **Array** and **Arrays** for the creation and manipulation of array objects.

3.2.14 Java1626: Array Objects, Part 3¹³⁹

Revised: Fri Apr 01 17:06:27 CDT 2016

This module discusses various details regarding the use of array objects in Java, including:

- The members of an array object
- The interfaces implemented by array objects
- **Class** objects and array objects
- The classes named **Array** and **Arrays**

3.2.14.4 Discussion and sample code

Members of an array object

An array object has the following members *(in addition to the data stored in the object)*:

- A public **final** variable named **length** , which contains the number of components of the array *(length may be positive or zero)*
- A public method named **clone** . This method overrides the method of the same name in **Object** class.
- Default versions of all the methods inherited from the class named **Object** , *(other than **clone** , which is overridden as described above).*

Implements Cloneable and Serializable

Also, every array object implements the **Cloneable** and **Serializable** interfaces. *(Note that neither of these interfaces declares any methods.)*

What is the Cloneable interface?

Here is what Sun has to say about the **Cloneable** interface:

*"A class implements the **Cloneable** interface to indicate to the **Object.clone()** method that it is legal for that method to make a field-for-field copy of instances of that class. Attempts to clone instances that do not implement the **Cloneable** interface result in the exception **CloneNotSupportedException** being thrown."*

Thus, the fact that an array object implements the **Cloneable** interface makes it possible to clone array objects.

A cloned array is shallow

While it is possible to clone arrays, care must be exercised when cloning multidimensional arrays. That is because a clone of a multidimensional array is shallow.

What does shallow mean?

Shallow means that the cloning process creates only a single new array.

Subarrays are shared between the original array and the clone.

(Although I'm not certain, I suspect that this may also be the case for cloning array objects containing references to ordinary objects. I will leave that determination as an exercise for the student. In any event, be careful if you clone array objects.)

Serialization

Serialization of an object is the process of decomposing the object into a stream of bytes, which can later be recomposed into a copy of the object. Here is what Sun has to say about the **Serializable** interface:

*"Serializability of a class is enabled by the class implementing the **java.io.Serializable** interface. Classes that do not implement this interface will not have any of their state serialized or deserialized.*

All subtypes of a serializable class are themselves serializable.

The serialization interface has no methods or fields and serves only to identify the semantics of being serializable."

Even though this quotation from Sun doesn't address array objects, because array objects implement the **Serializable** interface, they can be serialized and later reconstructed.

Class objects representing array objects

An object of the class named **Class** can be obtained (by calling the **getClass** method of the **Object** class) to represent the class from which an ordinary object was instantiated.

The **Class** object is able to answer certain questions about the class that it represents (such as the name of the superclass), and has other uses as well.

(One of the other uses is to specify the type as a parameter to the methods of the **Array** class, which I will illustrate later in this module.)

Every array also has an associated **Class** object.

That **Class** object is shared with all other arrays with the same component type.

The superclass of an array type is **Object**. (Think about this!)

An array of characters is not a string

For the benefit of the C/C++ programmers in the audience, an array of **char** is not a **String**.

(In Java, a string is an object of the **String** class or the **StringBuffer** class).

Not terminated by null

Also, neither a **String** object nor an array of type **char** is terminated by `'\u0000'` (the NUL character)

(This information is provided for the benefit of C programmers who are accustomed to working with so-called null-terminated strings. If you're not a C programmer, don't worry about this.)

A String object in Java is immutable

Once initialized, the contents of a Java **String** object never change.

On the other hand, an array of type **char** has mutable elements. The **String** class provides a method named **toCharArray**, which returns an array of characters containing the same character sequence as a **String**.

StringBuffer objects

The class named **StringBuffer** also provides a variety of methods that work with arrays of characters. The contents of a **StringBuffer** object are mutable.

The Array and Arrays classes

The classes named **Array** and **Arrays** provide methods that you can use to work with array objects.

The **Array** class provides static methods to dynamically create and access Java arrays.

The **Arrays** class contains various methods for manipulating arrays (such as sorting and searching). It also contains a static factory method that allows arrays to be viewed as lists.

A sample program named Array08

The sample program named **Array08** (shown in Listing 12 (p. 461) near the end of the module) illustrates the use of some of these methods.

Will discuss in fragments

As usual, I will discuss this program in fragments. Essentially all of the interesting code is in the method named **main**, so I will begin my discussion there. The first few fragments will illustrate the creation, population, and display of a one-dimensional array object whose elements contain references to objects of type **String**.

The newInstance method of the Array class

The code in Listing 1 (p. 452) calls the **static** method of the **Array** class named **newInstance** to create the array object and to store the object's reference in a reference variable of type **Object** named **v1**.

(Note that there are two overloaded versions of the **newInstance** method in the **Array** class. I will discuss the other one later.)

Listing 1 . Using the newInstance method.

continued on next page

```
Object v1 = Array.newInstance(
                    Class.forName("java.lang.String"),3);
```

Table 3.133

Two parameters required

This version of the `newInstance` method requires two parameters. The first parameter specifies the component type. This must be a reference to a `Class` object representing the component type of the new array object.

The second parameter, of type `int`, specifies the length of the new array object.

The Class object

The second parameter that specifies the array length is fairly obvious. However, you may need some help with the first parameter. Here is part of what Sun has to say about a `Class` object.

"Instances of the class `Class` represent classes and interfaces in a running Java application. Every array also belongs to a class that is reflected as a `Class` object that is shared by all arrays with the same element type and number of dimensions. The primitive Java types (boolean, byte, char, short, int, long, float, and double), and the keyword void are also represented as `Class` objects."

Getting a reference to a Class object

I know of three ways to get (or refer to) a `Class` object.

- `Class` objects for primitive types
- The `getClass` method
- The `forName` method

Class objects for primitive types

There are nine predefined `Class` objects that represent the eight primitive types and void. These are created by the Java Virtual Machine, and have the same names as the primitive types that they represent: `boolean`, `byte`, `char`, `short`, `int`, `long`, `float`, and `double`. You can refer to these class objects using the following syntax:

- `boolean.class`,
- `int.class`,
- `float.class`, etc.

I will illustrate this later in this module.

The getClass method

If you have a reference to a target object (*ordinary object or array object*), you can gain access to a `Class` object representing the class from which that object was instantiated by calling the `getClass` method of the `Object` class, on that object.

The `getClass` method returns a reference of type `Class` that refers to a `Class` object representing the class from which the target object was instantiated.

The forName method

The static `forName` method of the `Class` class accepts the name of a class or interface as an incoming `String` parameter, and returns the `Class` object associated with the class or interface having the given string name.

(The `forName` method cannot be used with primitive types as a parameter.)

Class object for the String class

Referring back to Listing 1 (p. 452), you will see that the first parameter passed to the `newInstance` method was a reference to a `Class` object representing the `String` class.

Thus, the statement in Listing 1 (p. 452) creates a one-dimensional array object, of component type **String**, three elements in length.

The reference to the array object is saved in the generic reference variable of type **Object**.

(In case you haven't recognized it already, this is an alternative to syntax such as

new String[3] .

Note that there are no square brackets in this alternative approach. Thus, it might be said that this approach is more mainstream OOP than the approach that requires the use of square brackets.)

Populate the array object

The code in Listing 2 (p. 454) uses two **static** methods of the **Array** class to populate the three elements of the array object with references to objects of type **String**.

Listing 2 . Populate the array object.

```
for(int i = 0; i < Array.getLength(v1);i++){
    Array.set(v1, i, "a"+i);
} //end for loop
```

Table 3.134

The getLength method

The **getLength** method of the **Array** class is used in Listing 2 (p. 454) to get the **length** of the array for use in the conditional expression of a **for** loop.

Note that unlike the sample programs in the previous module (*that stored the array object's reference as type **Object***), it was not necessary to cast the reference to type **String[]** in order to get the **length**.

The set method

The **set** method of the **Array** class is used in Listing 2 (p. 454) to store references to **String** objects in the elements of the array object.

Again, unlike the programs in the previous module, it was not necessary to cast the array reference to type **String[]** to access the elements. In fact, there are no square brackets anywhere in Listing 2 (p. 454).

Display the data

Listing 3 (p. 454) uses a similar **for** loop to display the contents of the **String** objects whose references are stored in the elements of the array object.

Listing 3 . Display the data.

```
for(int i = 0; i < Array.getLength(v1); i++){
    System.out.print(Array.get(v1, i) + " ");
} //end for loop
```

Table 3.135

No square brackets

Once again, note that no casts, and no square brackets were required in Listing 3 (p. 454). In fact, this approach makes it possible to deal with one-dimensional array objects using a syntax that is completely devoid of square brackets.

Rather than using square brackets to access array elements, this is a *method-oriented* approach to the use of array objects. This makes it possible to treat array objects much the same as we treat ordinary objects in Java.

A two-dimensional rectangular array object tree

Next, I will use the methods of the `Array` class to create, populate, and display a rectangular two-dimensional array object tree, whose elements contain references to objects of the class `String` .

Another overloaded version of `newInstance`

To accomplish this, I will use the other overloaded version of the `newInstance` method. This version requires a reference to an array object of type `int` as the second parameter.

(Note that the Sun documentation describes two different behaviors for this method, depending on whether the first parameter represents a non-array class or interface, or represents an array type. This sample program illustrates the first possibility.)

The second parameter

As mentioned above, the version of the `newInstance` method that I am going to use requires a reference to an array object of type `int` as the second parameter.

(The length of the array object of type `int` specifies the number of dimensions of the multi-dimensional array object. The contents of the elements of the array object of type `int` specify the sizes of those dimensions.)

Thus, my first task is to create and populate an array object of type `int` .

An array object of type `int`

Listing 4 (p. 455) shows the code required to create and populate the array object of type `int` . This is a one-dimensional array object having two elements (*length equals 2*). The first element is populated with the `int` value 2 and the second element is populated with the `int` value 3.

Listing 4 . An array object of type `int`.

```
Object v2 = Array.newInstance(int.class,2);
Array.setInt(v2, 0, 2);
Array.setInt(v2, 1, 3);
```

Table 3.136

Why do we need this array object?

When this array object is used later, in conjunction with the version of the `newInstance` method that requires a reference to an array object of type `int` as the second parameter, this array object will specify an array object having two dimensions (*a rectangular array*). The rectangular array will have two rows and three columns.

Same `newInstance` method as before

Note that Listing 4 (p. 455) uses the same version of the `newInstance` method that was used to create the one-dimensional array object in Listing 1 (p. 452) .

Class object representing `int`

Note the syntax of the first parameter passed to the `newInstance` method in Listing 4 (p. 455) . As mentioned earlier, this is a reference to the predefined `Class` object that represents the primitive type `int` . This causes the component type of the array object to be type `int` .

The `setInt` method

You should also note the use of the `setInt` method of the `Array` class to populate each of the two elements in the array in Listing 4 (p. 455) (*with `int` values of 2 and 3 respectively*).

The two-dimensional array object tree

Listing 5 (p. 456) uses the other overloaded version of the `newInstance` method to create a two-dimensional array object tree, having two rows and three columns.

Listing 5 . The two-dimensional array object tree.

```
Object v3 = Array.newInstance(Class.forName("java.lang.String"),
                             (int[])v2);
```

Table 3.137

A reference to the array object at the root of the tree is stored in the reference variable of type **Object** named **v3** . Note that the tree is designed to store references to objects of type **String** .

(The number of dimensions and the size of each dimension are specified by the reference to the array object of type **int[]** passed as the second parameter.)

Square-bracket cast is required here

The required type of the second parameter for this version of the **newInstance** method is **int[]** . Therefore, there was no way for me to avoid the use of square brackets. I could either store the reference to the array object as type **Object** and cast it before passing it to the method, (which I did), or save it originally as type **int[]** , (which I didn't). Either way, I would have to know about the type **int[]** .

Populate the leaf elements

The nested **for** loop in Listing 6 (p. 456) uses the various methods of the **Array** class to populate the elements in the leaf array objects with references to objects of the class **String** .

Listing 6 . Populate the leaf elements.

```
for(int i=0;i < Array.getLength(v3);i++){
for(int j=0;j < Array.getLength(Array.get(v3,i));j++){
    Array.set(Array.get(v3,i),j,"b" + (i+1)*(j+1));
} //end inner loop
} //end outer loop
```

Table 3.138

Admittedly, the code in Listing 6 (p. 456) is a little complex. However, there is really nothing new there, so I won't discuss it further.

Display the data

Similarly, the code in Listing 7 (p. 456) uses the methods of the **Array** class in a nested **for** loop to get and display the contents of the **String** objects whose references are stored in the elements of the leaf array objects. Again, there is nothing new here, so I won't discuss this code further.

Listing 7 . Display the data.

```
for(int i=0;i < Array.getLength(v3);i++){
for(int j=0;j < Array.getLength(Array.get(v3,i));j++){
    System.out.print(Array.get(Array.get(v3,i),j) + " ");
} //end inner loop
System.out.println();
} //end outer loop
System.out.println();
```

Table 3.139

Very few square brackets

I will point out that with the exception of the requirement to create and pass an array object as type `int[]`, it was possible to write this entire example without the use of square brackets. This further illustrates the fact that the `Array` class makes it possible to create and work with array objects in a *method-oriented* manner, almost devoid of the use of square-bracket notation.

Sorting and Searching

Many college professors require their students to spend large amounts of time reinventing algorithms for sorting and searching (*and for various collections and data structures as well*). There was probably a time in history when that was an appropriate use of a student's time. However, in my opinion, that time has passed.

Reuse, don't reinvent

Through a combination of the `Arrays` class, and the `Java Collections Framework`, most of the sorting, searching, data structures, and collection needs that you might have are readily available without a requirement for you to reinvent them.

(*One of the most important concepts in OOP is reuse, don't reinvent.*)

I will now illustrate sorting and searching using `static` methods of the `Arrays` class.

(*Note that the `Arrays` class is different from the `Array` class discussed earlier.*)

Create, populate, and display an array object

To give us something to work with, Listing 8 (p. 457) creates, populates, and displays the contents of an array object. Note that the array object is populated with references to `String` objects. There is nothing new here, so I won't discuss the code in Listing 8 (p. 457) in detail.

Listing 8 . Create, populate, and display an array object.

```

Object v4 = Array.newInstance(Class.forName("java.lang.String"),
                             8);
//Populate the array object.
// Create a gap in the data.
for(int i = 0; i < Array.getLength(v4); i++){
    if(i < 4){
        Array.set(v4,i,"c"+(8-i));}
    else{
        Array.set(v4,i,"c"+(18-i));}
} //end for loop

//Display the raw data
for(int i = 0; i < Array.getLength(v4); i++){
    System.out.print(Array.get(v4,i)+ " ");
} //end for loop

```

Table 3.140

The output

The code in Listing 8 (p. 457) produces the following output on the screen:

```
c8 c7 c6 c5 c14 c13 c12 c11
```

Note that the order of this data is generally descending, and there is no string encapsulating the characters **c4** .

Sort and display the data

The code in Listing 9 (p. 458) uses the **sort** method of the **Arrays** class to sort the array data into ascending order.

Listing 9 . Sort and display the data.

```
Arrays.sort((Object[])v4);

//Display the sorted data
for(int i = 0; i < Array.getLength(v4); i++){
    System.out.print(Array.get(v4, i) + " ");
} //end for loop
```

Table 3.141

The output

The code in Listing 9 (p. 458) displays the sorted contents of the array object, producing the following **output on the computer screen** :

```
c11 c12 c13 c14 c5 c6 c7 c8
```

Note that the order of the data in the array object has been modified, and the array data is now in ascending order.

*(This order is based on the natural ordering of the **String** data. I discuss other ways to order sorted data in conjunction with the **Comparable** and **Comparator** interfaces in my modules on the Java Collections Framework ¹⁴² .)*

Binary search

A binary search is a search algorithm that can very quickly find an item stored in a sorted collection of items. In this case, the collection of items is stored in an array object, and the data is sorted in ascending order.

Search for an existing string

Listing 10 (p. 458) uses the **binarySearch** method of the **Arrays** class to perform a search for an existing **String** object whose reference is stored in the sorted array. The code searches for the reference to the **String** object encapsulating the characters **c5** .

Listing 10 . Search for an existing string.

```
System.out.println(Arrays.binarySearch((Object[])v4,"c5"));
```

Table 3.142

The result of the search

The code in Listing 10 (p. 458) displays the numeral 4 on the screen.

¹⁴²<http://cnx.org/contents/dzOvxPFw:BaPSYl18>

When the `binarySearch` method finds a match, it returns the index value of the matching element. If you go back and look at the sorted contents (p. 458) of the array shown earlier, you will see that this is the index of the element containing a reference to a `String` object that encapsulates the characters `c5`.

Search for a non-existing string

The code in Listing 11 (p. 459) uses the `binarySearch` method to search for a reference to a `String` object that encapsulates the characters `c4`. As I indicated earlier, a `String` object that encapsulates these characters is not represented in the sorted array object.

Listing 11 . Search for a non-existing string.

```
System.out.println(Arrays.binarySearch((Object[])v4,"c4"));
```

Table 3.143

The result of the search

The code in Listing 11 (p. 459) produces the following negative numeral on the screen: `-5`.

Here is Sun's explanation for the value returned by the `binarySearch` method:

"Returns: index of the search key, if it is contained in the list; otherwise, $-(\text{insertion point}) - 1$. The insertion point is defined as the point at which the key would be inserted into the list: the index of the first element greater than the key, or `list.size()`, if all elements in the list are less than the specified key. Note that this guarantees that the return value will be ≥ 0 if and only if the key is found."

Thus, the negative return value indicates that the method didn't find a match. The absolute value of the return value can be used to determine the index of the reference to the target object if it did exist in the sorted list. I will leave it as an exercise for the student to interpret Sun's explanation beyond this simple explanation.

Other capabilities

In addition to sorting and searching, the `Arrays` class provides several other methods that can be used to manipulate the contents of array objects in Java.

3.2.14.5 Summary

An array object has the following members (*in addition to the data stored in the object*):

- A public final variable named `length`
- An overridden version of the public method named `clone`
- Default versions of all the other methods inherited from the class named `Object`

Every array object implements the `Cloneable` and `Serializable` interfaces.

A clone of a multidimensional array is shallow. Therefore, you should exercise caution when cloning array objects.

Because array objects implement the `Serializable` interface, they can be serialized and later reconstructed.

Every array also has an associated `Class` object.

The classes named `Array` and `Arrays` provide methods that you can use to work with array objects.

The `Array` class provides static methods to dynamically create and access Java array objects.

The `Arrays` class contains various methods for manipulating arrays (*such as sorting and searching*). It also contains a static factory method that allows arrays to be viewed as lists.

Class objects are required when using the methods of the `Array` class to dynamically create Java array objects.

There are nine predefined **Class** objects that represent the eight primitive types and void. They are accessed using the following syntax: `boolean.class`, `int.class`, etc.

Three ways to get a **Class** object are:

- Class objects for primitive types: `int.class` , etc.
- The `getClass` method
- The `forName` method

The methods of the **Array** class make it possible to deal with one-dimensional array objects using a syntax that is completely devoid of square brackets. This is a *method-oriented* approach to the use of array objects. This makes it possible to treat array objects much the same as we treat ordinary objects in Java. The required syntax for multi-dimensional array objects is mostly devoid of square brackets.

The **Arrays** class provides methods for sorting and searching array objects as well as performing other operations on array objects as well.

Through a combination of the **Arrays** class and the Java Collections Framework, most of the sorting, searching, data structures, and collection needs that you might have are readily available without a requirement for you to reinvent them.

3.2.15.3 Preview

This module explains the use of the keywords **this** and **super** . Short sample programs illustrate how you can use these keywords for several purposes.

I will discuss and illustrate the use of the **this** keyword in the following situations:

- To bypass local variables or parameters that hide member variables having the same name, in order to access the member variable.
- To make it possible for one overloaded constructor to call another overloaded constructor in the same class.
- To pass a reference to the current object to a method belonging to a different object (*as in implementing callbacks, for example*).

I will also discuss and illustrate the use of the **super** keyword in the following situations:

- To bypass the overridden version of a method in a subclass and execute the version in the superclass.
- To bypass a member variable in a subclass in order to access a member variable having the same name in a superclass.
- To cause a constructor in a subclass to call a parameterized constructor in the immediate superclass.

3.2.15.4 Discussion and sample code

You already know quite a lot about OOP

By now you know that an *object* is an *instance of a class* . You know that all variables and methods in Java must be contained in a class or an object. You know that the three primary characteristics of an object-oriented programming language are:

- *encapsulation*
- *inheritance*
- *polymorphism* .

If you have been studying this series of modules on the Essence of OOP in Java, you already know quite a lot about OOP in general, and the implementation of OOP in Java in particular.

A few more important OOP/Java concepts

However, there are a few more important concepts that I haven't previously discussed in this series of modules. In this module, I will explain the use of the keywords **this** and **super** .

Data and methods

The class provides the plan from which objects are built. This plan defines the *data* that is to be stored in an object, and the *methods* for manipulating that data. The data is variously referred to as *data members*, *fields* , and *variables* , depending on which book you are reading.

Non-static and static

The data can be further sub-divided into *non-static* and *static* , often referred to as *instance variables* and *class variables* respectively.

The methods are also often referred to as *member methods* , and they can also be *static* or *non-static* . Static methods are often referred to as *class methods* while non-static methods are often referred to as *instance methods* .

Instance variables and instance methods

The class body contains the *declarations* for, and possibly the *initialization* of all data members (*both class variables and instance variables*) as well as the full definition of all *methods* .

In this module, we will be particularly interested in instance variables and instance methods.

Every class is a subclass of Object

By default, every class in Java extends (*either directly or indirectly*) the class named **Object** . A new class may either extend **Object** , or extend another class that extends **Object** , or extend another class further down the inheritance hierarchy.

The immediate parent class of a new class is known as its *superclass* , and the new class is known as the *subclass* .

(*Sometimes we use the word superclass to indicate the collection of classes in the inheritance hierarchy from which a specific class is derived.*)

If you do not specify the *superclass* for a new class, it will extend **Object** by default.

The **extends** keyword

The keyword **extends** is used in the class declaration to specify the immediate *superclass* of the new class using the syntax shown in Figure 1 (p. 464) .

Figure 1 . The extends keyword.

```
class NewClass extends SuperClassName{
    //body of class
} //end class definition
```

Table 3.145

Inheritance

A class inherits the variables and methods of its superclass, and of the superclass of that class, etc., all the way back up the family tree to the single class **Object** , which is the root of all inheritance.

Thus, an object that is instantiated from a class contains all the instance variables and all the instance methods defined by that that class and defined by all its ancestors.

However, the methods may have been *overridden* one or more times along the way. Also, access to those variables and methods may have been restricted through the use of the **public** , **private** , and **protected** keywords.

(*There is another access level, often referred to as **package private** , which is what you get when you don't use an access keyword.*)

The **this** keyword

Every instance method in every object in Java receives a reference named **this** when the method is called. The reference named **this** is a reference to the object on which the method was called. It can be used for any purpose for which such a reference is needed.

Three common situations

There are at least three common situations where such a reference is needed:

- To bypass local variables or parameters that hide member variables having the same name, in order to access the member variable.
- To make it possible for one overloaded constructor to call another overloaded constructor in the same class.
- To pass a reference to the current object to a method belonging to a different object (*as in implementing callbacks, for example*).

Normally, instance methods belonging to an object have direct access to the instance variables belonging to that object, and to the class variables belonging to the class from which that object was instantiated.

(*Class methods never have access to instance variables or instance methods.*)

Name can be duplicated

However, the name of a method parameter or constructor parameter can be the same as the name of an instance variable belonging to the object or a class variable belonging to the class. It is also allowable for

the name of a local variable to be the same as the name of an instance variable or a class variable. In this case, the local variable or the parameter is said to *hide* the member variable having the same name.

Reference named *this* is passed to instance methods

As mentioned above, whenever an instance method is called on an object, a hidden reference named **this** is always passed to the method. The **this** reference always refers to the object on which the method was called. This makes it possible for the code in the method to refer back to the object on which the method was called.

The reference named **this** can be used to access the member variables hidden by the local variables or parameters having of the same name.

The sample program named This01

The sample program shown in Listing 1 (p. 466) illustrates the use of the **this** reference to access a hidden instance variable named **myVar** and a hidden class variable named **yourVar** .

Listing 1 . The program named This01 .

```

    /*File This01.java

    Illustrates use of this keyword to
    access hidden member variables.

    Tested using JDK 1.4.0 under Win2000

    The output from this program is:

    myVar parameter = 20
    local yourVar variable = 1
    Instance variable myVar = 5
    Class variable yourVar = 10
    *****/

class This01 {
    int myVar = 0;
    static int yourVar = 0;

    //Constructor with parameters named
    // myVar and yourVar
    public This01(int myVar,int yourVar){
        this.myVar = myVar;
        this.yourVar = yourVar;
    }//end constructor
    //-----//

    //Method with parameter named myVar
    // and local variable named yourVar
    void myMethod(int myVar){
        int yourVar = 1;
        System.out.println(
            "myVar parameter = " + myVar);
        System.out.println(
            "local yourVar variable = "
            + yourVar);
        System.out.println(
            "Instance variable myVar = "
            + this.myVar);
        System.out.println(
            "Class variable yourVar = "
            + this.yourVar);
    }//end myMethod
    //-----//

    public static void main(
        String[] args){
        This01 obj = new This01(5,10);
        obj.myMethod(20);
    }//end main method
} //End This01 class definition.

```

Table 3.146**The key points**

The key points to observe in the program is Listing 1 (p. 466) are:

- When the code refers to **myVar** or **yourVar** , the reference resolves to either an incoming parameter or to a local variable having that name.
- When the code refers to **this.myVar** or **this.yourVar** , the reference resolves to the corresponding instance variable and class variable having that name.

To summarize this situation, every time an instance method is called, it receives a hidden reference named **this** . That is a reference to the object on which the method was called.

The code in the method can use that reference to access any instance member of the object on which it was called, or any class member of the class from which the object was instantiated.

However, when class methods are called, they do not receive such a hidden reference, and therefore, they cannot refer to any instance members of any object instantiated from the class. They can only access class members of the same class.

Calling other constructors of the same class

Now I am going to discuss and illustrate the second common situation listed earlier.

A class can define two or more overloaded constructors having the same name and different argument lists. Sometimes it is useful for one overloaded constructor to call another overloaded constructor in the same class. When this is done, the constructor being called is referred to as though it were a method whose name is **this** , and whose argument list matches the argument list of the constructor being called.

The sample program named This02

This situation is illustrated in the program named **This02** shown in Listing 2 (p. 468) .

Listing 2 . The program named This02.

```

    /*File This02.java

overloaded constructor to access
another overloaded constructor of the
same class.

Tested using JDK 1.4.0 under Win2000

The output from this program is:

Instance variable myVar = 15
*****/

class This02 {
    int myVar = 0;

    public static void main(
        String[] args){
        This02 obj = new This02();
        obj.myMethod();
    }//end main method
    //-----//

    //Constructor with no parameters
    public This02(){
        //Call parameterized constructor
        this(15);
    }//end constructor
    //-----//

    //Constructor with one parameter
    public This02(int var){
        myVar = var;
    }//end constructor
    //-----//

    //Method to display member variable
    // named myVar
    void myMethod(){
        System.out.println(
            "Instance variable myVar = "
            + myVar);
    }//end myMethod

} //End This02 class definition.

```

Table 3.147

Calling a *noarg* constructor

The **main** method in Listing 2 (p. 468) instantiates a new object by applying the **new** operator to the *noarg* constructor for the class named **This02** .

(The common jargon for a constructor that doesn't take any parameters is a noarg constructor.)

The *noarg* constructor calls a parameterized constructor

The code in the *noarg* constructor uses the **this** keyword to call the other overloaded constructor, passing an **int** value of 15 as a parameter.

That constructor stores the value of the incoming parameter (15) in the instance variable named **myVar** . Then control returns to the *noarg* constructor, which in turn returns control to the **main** method. When control returns to the **main** method, the new object has been constructed, and the instance variable named **myVar** belonging to that object contains the value 15.

Display the value of the instance variable

The next statement in the **main** method calls the method named **myMethod** on the object, which causes the value stored in the instance variable (15) to be displayed on the screen.

The most important statement

For purposes of this discussion, the most important statement in the program is the statement that reads:

```
this(15);
```

This is the statement used by one overloaded constructor to call another overloaded constructor.

Callbacks

An extremely important concept in programming is the third situation mentioned in the earlier list (p. 464) . This is a situation where a method in one object calls a method in another object and passes a reference to itself as a parameter.

(This is sometimes referred to as registration. That is to say, one object registers itself on another object.)

The method in the second object saves the reference that it receives as an incoming parameter. This makes it possible for a method in the second object to make a callback to the first object sometime later. This is illustrated in the program named **This03** , shown in Listing 3 (p. 470) .

Listing 3 . The program named This03 .

```

    /*File This03.java

    Illustrates using the this keyword in
    a callback scenario.

    Tested using JDK 1.4.0 under Win2000

    The output from this program is:

    Instance variable myVar = 15
    *****/

class This03 {
    public static void main(
        String[] args){
        ClassA objA = new ClassA();
        ClassB objB = new ClassB();
        objA.goRegister(objB);
        objB.callHimBack();
        objA.showData();
    } //end main method
} //End This03 class definition.
//=====//

class ClassA{
    int myVar;

    void goRegister(ClassB refToObj){
        refToObj.registerMe(this);

    } //end goRegister
    //-----//

    void callMeBack(int var){
        myVar = var;
    } //end callMeBack
    //-----//

    void showData(){
        System.out.println(
            "Instance variable myVar = "
            + myVar);
    } //end showData
} //end ClassA
//=====//

class ClassB{
    ClassA ref;

    void registerMe(ClassA var){
        ref = var;
    } //end registerMe
    //-----//

```

Table 3.148

Not intended to be useful

Note that the program in Listing 3 (p. 470) is intended solely to illustrate the concept of a callback, and is not intended to do anything useful. This is a rather long and convoluted explanation, so please bear with me.

The **main** method begins by instantiating two objects, one each from the classes named **ClassA** and **ClassB**.

Go register yourself

Then the **main** method sends a message to **objA** telling it to go register itself on **objB**. A reference to **objB** is passed as a parameter to the method named **goRegister** belonging to **objA**.

The code in **objA** uses this reference to call the method named **registerMe** on **objB**, passing **this** as a parameter. In other words, the code in **objA** calls a method belonging to **objB** passing a reference to itself as a parameter. The code in **objB** saves that reference in an instance variable for later use.

Make a callback

Then the **main** method sends a message to **objB** asking it to use the saved reference to make a callback to **objA**. The code in the method named **callHimBack** uses the reference to **objA** saved earlier to call the method named **callMeBack** on **objA**, passing 15 as a parameter. The method named **callMeBack** belonging to **objA** saves that value in an instance variable.

Show the data

Finally, the **main** method calls the **showData** method on **objA** to cause the value stored in the instance variable belonging to **objA** to be displayed on the computer screen.

Callbacks are important

Again, this program is provided solely to illustrate the concept of a callback using the **this** keyword. In practice, callbacks are used throughout Java, but they are implemented in a somewhat more elegant way, making use of interfaces.

For example, interfaces with names like **Observer** and **MouseListener** are commonly used to register *observer* objects on *observable* objects (*sometimes referred to as listeners and sources*). Then later in the program, when something of interest happens on the *observable* object (*the source*), all registered *observer* objects (*the listeners*), are notified of the event.

The main point regarding the *this* reference

The main point of this discussion is that the **this** reference is available to all instance methods belonging to an object, and can be used whenever there is a need for a reference to the object on which the method is called.

To disambiguate something

At least one prominent author uses the word *disambiguate* to describe the process described by the first item in the earlier list (p. 464), where the **this** keyword is used to bypass one variable in favor of a different variable having the same name. I will also use that terminology in the following discussion.

Three uses of the *super* keyword

Here are three common uses of the **super** keyword:

- If your class *overrides* a method in a superclass, you can use the **super** keyword to bypass the overridden version in the class and execute the version in the superclass.
- If a local variable in your method or a member variable in your class hides a member variable in the superclass (*having the same name*), you can use the **super** keyword to access the member variable in the superclass.
- You can also use **super** in a constructor of your class to call a parameterized constructor in the superclass.

The program named Super3

The program in Listing 4 (p. 473) uses **super** to call a parameterized constructor in the superclass from the subclass constructor. This is an important use of **super**.

The program also uses **this** and **super** to disambiguate a local variable, an instance variable of the subclass, and an instance variable of the superclass. All three variables have the same name.

Listing 4 . The program named Super3 .

            "Setting superclass instance "
            + "var to " + val);

    //Subclass constructor
    public Super3(){
        //Call parameterized SuperClass

```

Table 3.149

The keyword `super` is used twice in the program in Listing 4 (p. 473) .

Call a parameterized constructor

The first usage of the keyword `super` appears as the first executable statement in the `noarg` constructor for the class named `Super3` . This statement reads as follows:

```
super(500);
```

This statement causes the parameterized constructor for the immediate superclass (*the class named `SuperClass`*) of the class named `Super3` , to be executed before the remaining code in the constructor for `Super3` is executed.

This is the mechanism by which you can cause a parameterized constructor in the immediate superclass to be executed.

What if you don't do this?

If you don't do this, an attempt will always be made to call a `noarg` constructor on the superclass before executing the remaining code in the constructor for your class.

(That is why you should almost always make certain that the classes that you define have a `noarg` constructor in addition to any parameterized constructors that you may define.)

First executable statement in constructor

When `super(parameters)` is used to call the superclass constructor, it must always be the first executable statement in the constructor.

Whenever you call the constructor of a class to instantiate an object, if your constructor doesn't have a call to `super` as the first executable statement in the constructor, the call to the `noarg` constructor in the superclass is made automatically.

In other words, in order to construct an object of a class, it is necessary to first construct that part of the object attributable to the superclass. That normally happens automatically, making use of the superclass constructor that doesn't take any parameters.

Calling a parameterized constructor

If you want to use a version of the superclass constructor that takes parameters, you can make your own call to `super(parameters)` as the first executable statement in your constructor (*as was done in this program*).

Accessing a superclass member variable

The second use of the `super` keyword in the program shown in Listing 4 (p. 473) uses the keyword to bypass an instance variable named `data` in the class named `Super3` , to access and display the value of an instance variable named `data` in the superclass named `SuperClass` .

Note that in that same section of code, the `this` keyword is used to bypass a local variable named `data` in order to display the value of an instance variable named `data` in the class named `Super3` .

Similarly, a statement without the use of either `this` or `super` is used to display the value of a local variable named `data` .

To disambiguate

Therefore, as stated earlier, the program uses `this` and `super` to disambiguate a local variable, an instance variable of the subclass, and an instance variable of the superclass, where all three variables have the same name.

Accessing overridden superclass method

As mentioned earlier (p. 471) , if your method *overrides* a method in its superclass, you can use the keyword `super` to call the overridden version in the superclass, possibly completely bypassing the overridden version in the subclass.

The program named Super4

This is illustrated by the program in Listing 5 (p. 476) . This program contains an overridden version of a superclass method named `meth` . The subclass version uses the value of an incoming parameter to decide whether to call the superclass version and then to call some of its own code, or to execute its own code exclusively.

    }//end meth

            "Entering overridden method "
            + "in subclass");
        //Decide whether to call

                "Incoming parameter is " + par);
            System.out.println(

Table 3.150**Only one statement contains super**

The **super** keyword is used in only one statement in the program in Listing 5 (p. 476) . That statement appears in the subclass version of an overridden method, and is as follows:

```
super.meth(par);
```

This statement is inside the body of an **if** statement. If the value of **par** is true, then this statement is executed, causing the superclass version of the method named **meth** to be executed (*passing the value of **par** as a parameter to the superclass method*). When the method returns, the remaining code in the subclass version of the method is executed.

If the value of **par** is false, the above statement is bypassed, and the superclass version of the method doesn't get executed. In this case, only the code in the subclass version is executed.

3.2.15.5 Summary

I have discussed and illustrated the use of the **this** keyword in the following common situations:

- To bypass local variables or parameters that hide member variables having the same name, in order to access the member variable.
- To make it possible for one overloaded constructor to call another overloaded constructor in the same class.
- To pass a reference to the current object to a method belonging to a different object (*as in implementing callbacks, for example*).

I have also discussed and illustrated the use of the **super** keyword in the following situations:

- To bypass the overridden version of a method in a subclass and execute the version in the superclass.
- To bypass a member variable in a subclass in order to access a member variable having the same name in a superclass.
- To cause a constructor in a subclass to call a parameterized constructor in the immediate superclass.

This module explains Exception Handling in Java. The discussion includes the following topics:

- What is an exception?
- How do you throw and catch exceptions?
- What do you do with an exception once you have caught it?
- How do you make use of the exception class hierarchy provided by the Java development environment?

This module will cover many of the details having to do with exception handling in Java. By the end of the module, you should know that the use of exception handling is not optional in Java, and you should have a pretty good idea how to use exception handling in a beneficial way.

3.2.16.4 Discussion and sample code

Introduction

Stated simply, the exception-handling capability of Java makes it possible for you to:

- Monitor for exceptional conditions within your program
- Transfer control to special exception-handling code (*which you design*) if an exceptional condition occurs

The basic concept

This is accomplished using the keywords: **try** , **catch** , **throw** , **throws** , and **finally** . The basic concept is as follows:

- You **try** to execute the statements contained within a block of code. (*A block of code is a group of one or more statements surrounded by curly brackets.*)
- If you detect an exceptional condition within that block, you **throw** an exception object of a specific type.

- You **catch** and process the exception object using code that you have designed.
- You optionally execute a block of code, designated by **finally** , which needs to be executed whether or not an exception occurs. (Code in the **finally** block is normally used to perform some type of cleanup.)

Exceptions in code written by others

There are also situations where you don't write the code to **throw** the exception object, but an exceptional condition that occurs in code written by someone else transfers control to exception-handling code that you write.

For example, the **read** method of the **InputStream** class throws an exception of type **IOException** if an exception occurs while the **read** method is executing. In this case, you are responsible only for the code in the **catch** block and optionally for the code in the **finally** block.

(This is the reason that you must surround the call to **System.in.read()** with a **try** block followed by a **catch** block, or optionally declare that your method **throws** an exception of type **IOException** .)

Exception hierarchy, an overview

When an exceptional condition causes an exception to be *thrown* , that exception is represented by an object instantiated from the class named **Throwable** or one of its subclasses.

Here is part of what Sun has to say about the **Throwable** class:

*"The **Throwable** class is the superclass of all errors and exceptions in the Java language. Only objects that are instances of this class (or one of its subclasses) are thrown by the Java Virtual Machine or can be thrown by the Java **throw** statement. Similarly, only this class or one of its subclasses can be the argument type in a **catch** clause."*

Sun goes on to say:

*"Instances of two subclasses, **Error** and **Exception** , are conventionally used to indicate that exceptional situations have occurred. Typically, these instances are freshly created in the context of the exceptional situation so as to include relevant information (such as stack trace data)."*

The Error and Exception classes

The virtual machine and many different methods in many different classes throw *exceptions* and *errors* . I will have quite a lot more to say about the classes named **Error** and **Exception** later in this module.

Defining your own exception types

You may have concluded from the Sun quotation given above that you can define and **throw** exception objects of your own design, and if you did, that is a correct conclusion. (Your new class must extend **Throwable** or one of its subclasses.)

The difference between Error and Exception

As mentioned above, the **Throwable** class has two subclasses:

- **Error**
- **Exception**

What is an error?

What is the difference between an **Error** and an **Exception** ? Paraphrasing David Flanagan and his excellent series of books entitled Java in a Nutshell, an **Error** indicates that a non-recoverable error has occurred that should not be caught. Errors usually cause the Java virtual machine to display a message and exit.

Sun says the same thing in a slightly different way:

*"An **Error** is a subclass of **Throwable** that indicates serious problems that a reasonable application should not try to catch. Most such errors are abnormal conditions."*

For example, one of the subclasses of **Error** is named **VirtualMachineError** . This error is *"Thrown to indicate that the Java Virtual Machine is broken or has run out of resources necessary for it to continue operating."*

What is an exception?

Paraphrasing Flanagan again, an **Exception** indicates an abnormal condition that must be properly handled to prevent program termination.

Sun explains it this way:

*"The class **Exception** and its subclasses are a form of **Throwable** that indicates conditions that a reasonable application might want to catch."*

As of JDK 1.4.0, there are more than fifty known subclasses of the **Exception** class. Many of these subclasses themselves have numerous subclasses, so there is quite a lot of material that you need to become familiar with.

The **RuntimeException** class

One subclass of **Exception** is the class named **RuntimeException**. As of JDK 1.4.0, this class has about 30 subclasses, many which are further subclassed. The class named **RuntimeException** is a very important class.

Unchecked exceptions

The **RuntimeException** class, and its subclasses, are important not so much for what they do, but for what they don't do. I will refer to exceptions instantiated from **RuntimeException** and its subclasses as *unchecked* exceptions.

Basically, an unchecked exception is a type of exception that you can optionally handle, or ignore. If you elect to ignore the possibility of an unchecked exception, and one occurs, your program will terminate as a result. If you elect to handle an unchecked exception and one occurs, the result will depend on the code that you have written to handle the exception.

Checked exceptions

All exceptions instantiated from the **Exception** class, or from subclasses of **Exception** other than **RuntimeException** and its subclasses must either be:

- Handled with a **try** block followed by a **catch** block, or
- Declared in a **throws** clause of any method that can throw them

In other words, checked exceptions *cannot be ignored* when you write the code in your methods. According to Flanagan, the exception classes in this category represent routine abnormal conditions that should be anticipated and caught to prevent program termination.

Checked by the compiler

Your code must anticipate and either handle or declare checked exceptions. Otherwise, your program won't compile. (*These are exception types that are checked by the compiler.*)

Throwable constructors and methods

As mentioned above, all errors and exceptions are subclasses of the **Throwable** class. As of JDK 1.4.0, the **Throwable** class provides four constructors and about a dozen methods. The four constructors are shown in Figure 1 (p. 481).

Figure 1 . Throwable constructors.

```
Throwable()
Throwable(String message)
Throwable(String message,Throwable cause)
Throwable(Throwable cause)
```

Table 3.151

The first two constructors have been in Java for a very long time. Basically, these two constructors allow you to construct an exception object with, or without a **String** message encapsulated in the object.

New to JDK 1.4

The last two constructors are new in JDK 1.4.0. These two constructors are provided to support the *cause facility*. The *cause facility* is new in release 1.4. It is also known as the *chained exception* ¹⁴⁹ facility. (I won't cover this facility in this module. Rather, I plan to cover it in a series of future modules.)

Methods of the Throwable class

Figure 2 (p. 482) shows some of the methods of the **Throwable** class. (I omitted some of the methods introduced in JDK 1.4 for the reasons given above.)

Figure 2 . Methods of the Throwable class.
<pre>fillInStackTrace() getStackTrace() printStackTrace(). setStackTrace(StackTraceElement[] stackTrace) getLocalizedMessage() getMessage() toString()</pre>

Table 3.152**The StackTrace**

The first four methods in Figure 2 (p. 482) deal with the *StackTrace* . In case you are unfamiliar with the term *StackTrace*, this is a list of the methods executed in sequence that led to the exception. (This is what you typically see on the screen when your program aborts with a runtime error that hasn't been handled.)

Messages

The two methods dealing with messages provide access to a **String** message that may be encapsulated in the exception object. The **getMessage** class simply returns the message that was encapsulated when the object was instantiated. (If no message was encapsulated, this method returns null.)

The **getLocalizedMessage** method is a little more complicated to use. According to Sun, "Subclasses may override this method in order to produce a locale-specific message."

The toString method

The **toString** method is inherited from the **Object** class and overridden in the exception subclass to "return a short description of the **Throwable** ".

Inherited methods

All exception objects inherit the methods of the **Throwable** class, which are listed in Figure 2 (p. 482) . Thus, any of these methods may be called by the code in the **catch** block in its attempt to successfully handle the exception.

For example, exceptions may have a message encapsulated in the exception object, which can be accessed using the **getMessage** method. You can use this to display a message describing the error or exception.

You can also use other methods of the **Throwable** class to:

- Display a stack trace showing where the exception or error occurred
- Produce a **String** representation of the exception object

So, what is an exception?

According to the online book entitled The Java Tutorial ¹⁵⁰ by Campione and Walrath:

"The term exception is shorthand for the phrase "exceptional event". It can be defined as follows:

Definition: An exception is an event that occurs during the execution of a program that disrupts the normal flow of instructions."

When an exceptional condition occurs within a method, the method may instantiate an exception object and hand it off to the runtime system to deal with it. This is accomplished using the **throw** keyword. (This is called *throwing an exception*.)

To be useful, the exception object should probably contain information about the exception, including its type and the state of the program when the exception occurred.

Handling the exception

At that point, the runtime system becomes responsible for finding a block of code designed to handle the exception.

The runtime system begins its search with the method in which the exception occurred and searches backwards through the call stack until it finds a method that contains an *appropriate* exception handler (*catch block*).

An exception handler is *appropriate* if the type of the exception thrown is the same as the type of exception handled by the handler, or is a subclass of the type of exception handled by the handler.

Thus, the requirement to handle an exception that has been thrown progresses up through the call stack until an appropriate handler is found to handle the exception. If no appropriate handler is found, the runtime system and the program terminate.

(If you have ever had a program terminate with a **NullPointerException**, then you know how program termination works).

According to the jargon, the exception handler that is chosen is said to *catch the exception*.

Advantages of using exception handling

According to Campione and Walrath, exception handling provides the following advantages over "traditional" error management techniques:

- Separating Error Handling Code from "Regular" Code
- Propagating Errors Up the Call Stack
- Grouping Error Types and Error Differentiation

Separating error handling code from regular code

I don't plan to discuss these advantages in detail. Rather, I will simply refer you to The Java Tutorial ¹⁵¹ and other good books where you can read their discussions. However, I will comment briefly.

Campione and Walrath provide a good illustration where they show how a simple program having about six lines of code get "bloated" into about 29 lines of very confusing code through the use of traditional error management techniques. Not only does the program suffer bloat, the logical flow of the original program gets lost in the clutter of the modified program.

They then show how to accomplish the same error management using exception handling. Although the version with exception handling contains about seventeen lines of code, it is orderly and easy to understand. The additional lines of code do not cause the original logic of the program to get lost.

You must still do the hard work

However, the use of exception handling does not spare you from the hard work of detecting, reporting, and handling errors. What it does is provide a means to separate the details of what to do when something out-of-the-ordinary happens from the normal logical flow of the program code.

Propagating exceptions up the call stack

Sometimes it is desirable to propagate exception handling up the call stack and let the corrective action be taken at a higher level.

¹⁵⁰<http://java.sun.com/docs/books/tutorial/>

¹⁵¹<http://java.sun.com/docs/books/tutorial/>

For example, you might provide a class with methods that implement a *stack*. One of the methods of your class might be to *pop* an element off the stack.

What should your program do if a using program attempts to pop an element off an empty stack? That decision might best be left to the user of your stack class, and you might simply propagate the notification up to the calling method and let that method take the corrective action.

Grouping exception types

When an exception is thrown, an object of one of the exception classes is passed as a parameter. Objects are instances of classes, and classes fall into an inheritance hierarchy in Java. Therefore, a natural hierarchy can be created, which causes exceptions to be grouped in logical ways.

For example, going back to the stack example, you might create an exception class that applies to all exceptional conditions associated with an object of your stack class. Then you might extend that class into other classes that pertain to specific exceptional conditions, such as *push* exceptions, *pop* exceptions, and *initialization* exceptions.

When your code throws an exception object of a specific type, that object can be caught by an exception handler designed either to:

- Catch on the basis of a group of exceptions, or
- Catch on the basis of a subgroup of that group, or
- Catch on the basis of one of the specialized exceptions.

In other words, an exception handler can catch exceptions of the class specified by the type of its parameter, or can catch exceptions of any subclass of the class specified by the type of its parameter.

More detailed information on exception handling

As explained earlier, except for **Throwable** objects of type **Error** and for **Throwable.Exception** objects of type **RuntimeException**, Java programs must either *handle* or *declare* all **Exception** objects that are thrown. Otherwise, the compiler will refuse to compile the program.

In other words, all exceptions other than those specified above are *checked* by the compiler, and the compiler will refuse to compile the program if the exceptions aren't handled or declared. As a result, exceptions other than those specified above are often referred to as *checked* exceptions.

Catching an exception

Just to make certain that we are using the same terminology, a method *catches* an exception by providing an exception handler whose parameter type is appropriate for that type of exception object. (*I will more or less use the terms **catch** block and exception handler interchangeably.*)

The type of the parameter in the **catch** block must be the class from which the exception was instantiated, or a superclass of that class that resides somewhere between that class and the **Throwable** class in the inheritance hierarchy.

Declaring an exception

If the code in a method can throw a checked exception, and the method does not provide an exception handler for the type of exception object thrown, the method must *declare* that it can throw that exception. The **throws** keyword is used in the method declaration to declare that it **throws** an exception of a particular type.

Any checked exception that can be thrown by a method is part of the method's programming interface (see the *read* method of the *InputStream* class, which throws **IOException**, for example). Users of a method must know about the exceptions that a method can throw in order to be able to handle them. Thus, you must declare the exceptions that the method can throw in the method signature.

Checked exceptions

Checked exceptions are all exception objects instantiated from subclasses of the **Exception** class other than those of the **RuntimeException** class.

Exceptions of all **Exception** subclasses other than **RuntimeException** are checked by the compiler and will result in compiler errors if they are neither *caught* nor *declared*.

You will learn how you can create your own exception classes later. Whether your exception objects become checked or not depends on the class that you extend when you define your exception class.

(If you extend a checked exception class, your new exception type will be a checked exception. Otherwise, it will not be a checked exception.)

Exceptions that can be thrown within the scope of a method

The exceptions that can be thrown within the scope of a method include not only exceptions which are thrown by code written into the method, but also includes exceptions thrown by methods called by that method, or methods called by those methods, etc.

According to Campione and Walrath,

"This ... includes any exception that can be thrown while the flow of control remains within the method. Thus, this ... includes both exceptions that are thrown directly by the method with Java's throw statement, and exceptions that are thrown indirectly by the method through calls to other methods."

Sample programs

Now it's time to take a look at some sample code designed to deal with exceptions of the types delivered with the JDK. Initially I won't include exception classes that are designed for custom purposes. However, I will deal with exceptions of those types later in the module.

The first three sample programs will illustrate the successive stages of dealing with checked exceptions by either catching or declaring those exceptions.

Sample program with no exception handling code

The first sample program shown in Listing 1 (p. 485) neither catches nor declares the **InterruptedException** which can be thrown by the **sleep** method of the **Thread** class.

Listing 1 . Sample program with no exception handling code.

        String[] args){
        Excep11 obj = new Excep11();
        obj.myMethod();
    }//end main
    //-----//

    void myMethod(){
        Thread.currentThread().sleep(1000);
    }//end myMethod
} //end class Excep11

```

Table 3.153

A possible InterruptedException

The code in the **main** method of Listing 1 (p. 485) calls the method named **myMethod** . The method named **myMethod** calls the method named **sleep** of the **Thread** class. The method named **sleep** declares that it throws **InterruptedException** .

InterruptedException is a checked exception. The program illustrates the failure to either catch or declare **InterruptedException** in the method named **myMethod** .

As a result, this program won't compile. The compiler error is similar to that shown in Figure 3 (p. 486). Note the caret in the last line that points to the point where the compiler detected the problem.

Figure 3 . Compiler error from an unhandled checked exception.

Table 3.154

As you can see, the compiler detected a problem where the `sleep` method was called, because the method named `myMethod` failed to deal properly with an exception that can be thrown by the `sleep` method.

Sample program that fixes one compiler error

The next version of the program, shown in Listing 2 (p. 486), fixes the problem identified with the call to the `sleep` method, by declaring the exception in the signature for the method named `myMethod`.

Listing 2 . Sample program that fixes one compiler error.

    }//end main

    }//end myMethod
}//end class Excep12

```

Table 3.155

Another possible InterruptedException

As was the case in the previous program, this program also illustrates a failure to catch or declare an **InterruptedException** . However, in this case, the problem has moved up one level in the call stack relative to the problem with the program in Listing 1 (p. 485) .

This program also fails to compile, producing a compiler error similar to that shown in Figure 4 (p. 487) . Note that the caret indicates that the problem is associated with the call to **myMethod** .

<p>Figure 4 . Another compiler error.</p> <pre> unreported exception java.lang.InterruptedException; must be caught or declared to be thrown obj.myMethod(); ^ </pre>
--

Table 3.156

Didn't solve the problem

Simply declaring a checked exception doesn't solve the problem. Ultimately, the exception must be handled if the compiler problem is to be solved.

*(Note, however, that it is possible to declare that the **main** method throws a checked exception, which will cause the compiler to ignore it and allow your program to compile.)*

The program in Listing 2 (p. 486) eliminated the compiler error identified with the call to the method named **sleep** . This was accomplished by declaring that the method named **myMethod** *throws InterruptedException* . However, this simply passed the exception up the call stack to the next higher-level method in the stack. This didn't solve the problem, it simply handed it off to another method to solve.

The problem still exists, and is now identified with the call to **myMethod** where it will have to be handled in order to make the compiler error go away.

Sample program that fixes the remaining compiler error

The version of the program shown in Listing 3 (p. 488) fixes the remaining compiler error. This program illustrates both declaring and handling a checked exception. This program compiles and runs successfully.

Listing 3 . Sample program that fixes the remaining compiler error.

```

    /*File Excep13.java

    import java.lang.Thread;

    class Excep13{
    public static void main(
        String[] args){
        Excep13 obj = new Excep13();
        try{//begin try block
            obj.myMethod();
        }catch(InterruptedExcep13 e){
            System.out.println(
                "Handle exception here");
        }//end catch block
    }//end main
    //-----//

    void myMethod()
        throws InterruptedExcep13{
        Thread.currentThread().sleep(1000);
    }//end myMethod
    }//end class Excep13

```

Table 3.157

The solution to the problem

This solution to the problem is accomplished by surrounding the call to **myMethod** with a **try** block, which is followed immediately by an *appropriate* **catch** block. In this case, an appropriate **catch** block is one whose parameter type is either **InterruptedException**, or a superclass of **InterruptedException**.

(Note, however, that the superclass cannot be higher than the **Throwable** class in the inheritance hierarchy.)

The myMethod method declares the exception

As in the previous version, the method named **myMethod** (declares the exception and passes it up the call stack to the method from which it was called.

The main method handles the exception

In the new version shown in Listing 3 (p. 488), the **main** method provides a **try** block with an *appropriate* **catch** block for dealing with the problem (*although it doesn't actually deal with it in any significant way*). This can be interpreted as follows:

- Try to execute the code within the **try** block.
- If an exception occurs, search for a **catch** block that matches the type of object thrown by the exception.
- If such a **catch** block can be found, immediately transfer control to the catch block without executing any of the remaining code in the **try** block.

(For simplicity, this program didn't have any remaining code. Some later sample programs will illustrate code being skipped due to the occurrence of an exception.)

Not a method call

Note that this transfer of control is not a method call. It is an unconditional transfer of control. There is no *return* from a catch block.

Matching catch block was found

In this case, there was a matching **catch** block to receive control. In the event that an **InterruptedException** is thrown, the program would execute the statement within the body of the **catch** block, and then transfer control to the code following the final **catch** block in the group of **catch** blocks (*in this case, there was only one catch block*).

No output is produced

It is unlikely that you will see any output when you run this program, because it is unlikely that an **InterruptedException** will be thrown. (*I didn't provide any code that will cause such an exception to occur.*)

A sample program that throws an exception

Now let's look at the sample program in Listing 4 (p. 490) , which throws an exception and deals with it. This program illustrates the implementation of exception handling using the try/catch block structure.

Listing 4 . A sample program that throws an exception.

```

    /*File Excep14.java
    Copyright 2002, R. G. Baldwin

    Tested with JDK 1.4.0 under Win2000
    *****/

class Excep14{
    public static void main(
        String[] args){
        try{
            for(int cnt = 2; cnt >-1; cnt--){
                System.out.println(
                    "Running. Quotient is: "
                    + 6/cnt);
            }//end for-loop
        }//end try block
        catch(ArithmeticException e){
            System.out.println(
                "Exception message is: "
                + e.getMessage()
                + "\nStacktrace shows:");
            e.printStackTrace();
            System.out.println(
                "String representation is\n " +
                e.toString());
            System.out.println(
                "Put corrective action here");
        }//end catch block
        System.out.println(
            "Out of catch block");
    }//end main
}//end class Excep14

```

Table 3.158**Keeping it simple**

I try to keep my sample programs as simple as possible, introducing the minimum amount of complexity necessary to illustrate the main point of the program. It is easy to write a *really simple* program that throws an unchecked **ArithmeticException** . Therefore, the program in Listing 4 (p. 490) was written to throw an **ArithmeticException** . This was accomplished by trying to perform an integer divide by zero.

The try/catch structure is the same ...

It is important to note that the *try/catch* structure illustrated in Listing 4 (p. 490) would be the same whether the exception is checked or unchecked. The main difference is that you are not required by the compiler to handle unchecked exceptions and you are required by the compiler to either handle or declare checked exceptions.

Throwing an ArithmeticException

The code in Listing 4 (p. 490) executes a simple counting loop inside a **try** block. During each iteration, the counting loop divides the integer 6 by the value of the counter. When the value of the counter goes to zero, the runtime system tries to perform an integer divide by zero operation, which causes it to throw an **ArithmeticException** .

Transfer control immediately

At that point, control is transferred directly to the **catch** block that follows the **try** block. This is an *appropriate* **catch** block because the type of parameter declared for the **catch** block is **ArithmeticException** . It matches the type of the object that is thrown.

*(It would also be appropriate if the declared type of the parameter were a superclass of **ArithmeticException** , up to and including the class named **Throwable** . **Throwable** is a direct subclass of **Object** . If you were to declare the parameter type for the **catch** block as **Object** , the compiler would produce an incompatible type error.)*

Calling methods inside the catch block

Once control enters the **catch** block, three of the methods of the **Throwable** class are called to cause information about the situation to be displayed on the screen. The output produced by the program is similar to that shown in Figure 5 (p. 491) .

Key things to note

The key things to note about the code in Listing 4 (p. 490) and the output in Figure 5 (p. 491) are:

- The code to be protected is contained in a **try** block.
- The **try** block is followed immediately by an appropriate **catch** block.
- When an exception is thrown within the **try** block, control is transferred immediately to the **catch** block with the matching or appropriate parameter type.
- Although the code in the **catch** block simply displays the current state of the program, it could contain code that attempts to rectify the problem.
- Once the code in the **catch** block finishes executing, control is passed to the next executable statement following the **catch** block, which in this program is a print statement.

Doesn't attempt to rectify the problem

This program doesn't attempt to show how an actual program might recover from an exception of this sort. However, it is clear that (*rather than experiencing automatic and unconditional termination*) the program remains in control, and in some cases, recovery might be possible.

This sample program illustrates **try** and **catch** . The use of **finally** , will be discussed and illustrated later.

A nuisance problem explained

While we are at it, I would be remiss in failing to mention a nuisance problem associated with exception handling.

As you may recall, the scope of a variable in Java is limited to the block of code in which it is declared. A block is determined by enclosing code within a pair of matching curly brackets: {...}.

Since a pair of curly brackets is required to define a **try** block, the scope of any variables or objects declared inside the **try** block is limited to the **try** block.

While this is not an insurmountable problem, it may require you to modify your programming style in ways that you find distasteful. In particular, if you need to access a variable both within and outside the **try** block, you must declare it before entering the **try** block.

The process in more detail

Now that you have seen some sample programs to help you visualize the process, lets discuss the process in more detail.

The try block

According to Campione and Walrath,

"The first step in writing any exception handler is putting the Java statements within which an exception can occur into a try block. The try block is said to govern the statements enclosed within it and defines the scope of any exception handlers (established by subsequent catch blocks) associated with it."

Note that the terminology being used by Campione and Walrath treats the **catch block** as the "exception handler" and treats the **try** block as something that precedes one or more exception handlers. I don't disagree with their terminology. I mention it only for the purpose of avoiding confusion over terminology.

The syntax of a try block

The general syntax of a **try** block, as you saw in the previous program, has the keyword **try** followed by one or more statements enclosed in a pair of matching curly brackets, as shown in Figure 6 (p. 492) .

Figure 6 . Syntax of a try block.

```
try{
  //java statements
} //end try block
```

Table 3.160

Single statement and multiple exceptions

You may have more than one statement that can throw one or more exceptions and you will need to deal with all of them.

You could put each such statement that might throw exceptions within its own **try** block and provide separate exception handlers for each **try** block.

(Note that some statements, particularly those that call other methods, could potentially throw many different types of exceptions.)

Thus a **try** block consisting of a single statement might require many different exception handlers or **catch** blocks following it.

Multiple statements and multiple exceptions

You could put all or several of the statements that might throw exceptions within a single **try** block and associate multiple exception handlers with it. There are a number of practical issues involved here, and only you can decide in any particular instance which approach would be best.

The catch blocks must follow the try block

However you decide to do it, the exception handlers associated with a **try** block must be placed immediately following their associated *try* block. If an exception occurs within the **try** block, that exception is handled by the appropriate exception handler associated with the **try** block. If there is no appropriate exception handler associated with the **try** block, the system attempts to find an appropriate exception handler in the next method up the call stack.

A **try** block must be accompanied by at least one **catch** block (or one **finally** block). Otherwise, a compiler error that reads something like *'try' without 'catch' or 'finally'* will occur.

The catch block(s)

Continuing with what Campione and Walrath have to say:

"Next, you associate exception handlers with a try block by providing one or more catch blocks directly after the try block."

There can be no intervening code between the end of the **try** block and the beginning of the first **catch** block, and no intervening code between **catch** blocks.

Syntax of a catch block

The general form of a **catch** block is shown in Figure 7 (p. 493) .

Figure 7 . Syntax of a catch block.

```
catch(ThrowableObjectType paramName){
//Java statements to handle the
// exception
} //end catch block
```

Table 3.161

The declaration for the **catch** block requires a single argument as shown. The syntax for the argument declaration is the same as an argument declaration for a method.

Argument type specifies type of matching exception object

The argument type declares the type of exception object that a particular **catch** block can handle. The type must be **Throwable** , or a subclass of the **Throwable** class discussed earlier.

A parameter provides the local name

Also, as in a method declaration, there is a parameter, which is the name by which the handler can refer to the exception object. For example, in an earlier program, I used statements such as `e.getMessage()` to access an instance method of an exception object caught by the exception handler. In that case, the name of the parameter was `e` .

You access the instance variables and methods of exception objects the same way that you access the instance variables and methods of other objects.

Proper order of catch blocks

According to Campione and Walrath:

"The catch block contains a series of legal Java statements. These statements are executed if and when the exception handler is called. The runtime system calls the exception handler when the handler is the first one in the call stack whose type matches that of the exception thrown."

Therefore, the order of your exception handlers is very important, particularly if you have some handlers, which are further up the exception hierarchy than others.

Those handlers that are designed to handle exception types furthest from the root of the hierarchy tree (**Throwable**) should be placed first in the list of exception handlers.

Otherwise, an exception handler designed to handle a specific type of object may be preempted by another handler whose exception type is a superclass of that type, if the superclass exception handler appears earlier in the list of exception handlers.

Catching multiple exception types with one handler

Exception handlers that you write may be more or less specialized. In addition to writing handlers for very specialized exception objects, the Java language allows you to write general exception handlers that handle multiple types of exceptions.

A hierarchy of `Throwable` classes

Java exceptions are `Throwable` objects (*instances of the `Throwable` class or a subclass of the `Throwable` class*).

The Java standard library contains numerous classes that are subclasses of `Throwable` and thus build a hierarchy of `Throwable` classes.

According to Campione and Walrath:

"Your exception handler can be written to handle any class that inherits from `Throwable`. If you write a handler for a "leaf" class (a class with no subclasses), you've written a specialized handler: it will only handle exceptions of that specific type. If you write a handler for a "node" class (a class with subclasses), you've written a general handler: it will handle any exception whose type is the node class or any of its subclasses."

You have a choice

Therefore, when writing exception handlers, you have a choice. You can write a handler whose exception type corresponds to a node in the inheritance hierarchy, and it will be appropriate to `catch` exceptions of that type, or any subclass of that type.

Alternately, you can write a handler whose exception type corresponds to a *leaf*, in which case, it will be appropriate to `catch` exceptions of that type only.

And finally, you can mix and match, writing some exception handlers whose type corresponds to a node, and other exception handlers whose type corresponds to a leaf. In all cases, however, be sure to position your exception handlers in reverse subclass order, with the furthestmost subclass from the root appearing first, and the root class appearing last.

The `finally` block

And finally (*no pun intended*), Campione and Walrath tell us:

"Java's `finally` block provides a mechanism that allows your method to clean up after itself regardless of what happens within the `try` block. Use the `finally` block to close files or release other system resources."

To elaborate, the `finally` block can be used to provide a mechanism for cleaning up open files, etc., before allowing control to be passed to a different part of the program. You accomplish this by writing the cleanup code within a `finally` block.

Code in `finally` block is always executed

It is important to remember that the runtime system always executes the code within the `finally` block regardless of what happens within the `try` block.

If no exceptions are thrown, none of the code in `catch` blocks is executed, but the code in the `finally` block is executed.

If an exception is thrown and the code in an exception handler is executed, once the execution of that code is complete, control is passed to the `finally` block and the code in the `finally` block is executed.

(There is one important exception to the above. If the code in the `catch` block terminates the program by executing `System.exit(0)`, the code in the `finally` block will not be executed.)

The power of the `finally` block

The sample program shown in Listing 5 (p. 495) illustrates the power of the `finally` block.

Listing 5 . The power of the `finally` block.

Table 3.162

Execute return statement in catch block

The code in Listing 5 (p. 495) forces an **ArithmeticException** by attempting to do an integer divide by zero. Control is immediately transferred to the matching **catch** block, which prints a message and then executes a **return** statement.

Normally, execution of a **return** statement terminates the method immediately. In this case, however, before the method terminates and returns control to the calling method, the code in the **finally** block is executed. Then control is transferred to the **main** method, which called this method in the first place.

Figure 8 (p. 496) shows the output produced by this program.

Figure 8 . Output produced by the finally block.

```

```

Table 3.163

This program demonstrates that the **finally** block really does have the final word.

Declaring exceptions thrown by a method

Sometimes it is better to handle exceptions in the method in which they are detected, and sometimes it is better to pass them up the call stack and let another method handle them.

In order to pass exceptions up the call stack, you must *declare* them in your method signature.

To *declare* that a method throws one or more exceptions, you add a **throws** clause to the method signature for the method. The **throws** clause is composed of the **throws** keyword followed by a comma-separated list of all the exceptions thrown by that method.

The **throws** clause goes after the method name and argument list and before the curly bracket that defines the scope of the method.

Figure 9 (p. 496) shows the syntax for declaring that a method **throws** four different types of exceptions.

Figure 9 . Syntax for declaring that a method throws exceptions.

```
void myMethod() throws
    InterruptedException,
    MyException,
    HerException,
    UrException
{
    //method code
} //end myMethod()
```

Table 3.164

Assuming that these are checked exceptions, any method calling this method would be required to either handle these exception types, or continue passing them up the call stack. Eventually, some method must handle them or the program won't compile.

*(Note however that while it might not represent good programming practice, it is allowable to declare that the **main** method **throws** exceptions. This is a way to avoid handling checked exceptions and still get your program to compile.)*

The throw keyword

Before your code can **catch** an exception, some Java code must **throw** one. The exception can be thrown by code that you write, or by code that you are using that was written by someone else.

Regardless of who wrote the code that throws the exception, it's always thrown with the Java **throw** keyword. At least that is true for exceptions that are thrown by code written in the Java language.

*(Exceptions such as **ArithmeticException** are also thrown by the runtime system, which is probably not written using Java source code.)*

A single argument is required

When formed into a statement, the **throw** keyword requires a single argument, which must be a reference to an object instantiated from the **Throwable** class, or any subclass of the **Throwable** class. Figure 10 (p. 497) shows an example of such a statement.

Figure 10 . Example of a throw statement.

```
throw new myThrowableClass("Message");
```

Table 3.165

If you attempt to throw an object that is not instantiated from **Throwable** or one of its subclasses, the compiler will refuse to compile your program.

Defining your own exception classes

Now you know how to write exception handlers for those exception objects that are thrown by the runtime system, and thrown by methods in the standard class library.

It is also possible for you to define your own exception classes, and to cause objects of those classes to be thrown whenever an exception occurs. In this case, you get to decide just what constitutes an exceptional condition.

For example, you could write a data-processing application that processes integer data obtained via a TCP/IP link from another computer. If the specification for the program indicates that the integer value 10 should never be received, you could use an occurrence of the integer value 10 to cause an exception object of your own design to be thrown.

Choosing the exception type to throw

Before throwing an exception, you must decide on its type. Basically, you have two choices in this regard:

- Use an exception class written by someone else, such as the myriad of exception classes defined in the Java standard library.
- Define an exception class of your own.

An important question

So, an important question is, when should you define your own exception classes and when should you use classes that are already available. Because this is only one of many design issues, I'm not going to try to give you a ready answer to the question. However, I will refer you to The Java Tutorial ¹⁵² by Campione and Walrath where you will find a checklist to help you make this decision.

Choosing a superclass to extend

If you decide to define your own exception class, it must be a subclass of **Throwable** . You must decide which class you will extend.

The two existing subclasses of **Throwable** are **Exception** and **Error** . Given the earlier description of **Error** and its subclasses, it is not likely that your exceptions would fit the **Error** category. (*In concept, errors are reserved for serious hard errors that occur deep within the system.*)

Checked or unchecked exception

Therefore, your new class should probably be a subclass of **Exception** . If you make it a subclass of **RuntimeException** , it won't be a checked exception. If you make it a subclass of **Exception** , but not a subclass of **RuntimeException** , it will be a checked exception.

Only you can decide how far down the **Exception** hierarchy you want to go before creating a new branch of exception classes that are unique to your application.

Naming conventions

Many Java programmers append the word **Exception** to the end of all class names that are subclasses of **Exception** , and append the word **Error** to the end of all class names that are subclasses of **Error** .

¹⁵²<http://java.sun.com/docs/books/tutorial/>

One more sample program

Let's wrap up this module with one more sample program named **Excep16** . We will define our own exception class in this program. Then we will **throw** , **catch and** process an exception object instantiated from that class.

Discuss in fragments

This program is a little longer than the previous programs, so I will break it down and discuss it in fragments. A complete listing of the program is shown in Listing 10 (p. 501) .

The class definition shown in Listing 6 (p. 498) is used to construct a custom exception object that encapsulates a message. Note that this class extends **Exception** . *(Therefore, it is a checked exception.)*

Listing 6 . The class named MyException .

```
class MyException extends Exception{
  MyException(String message){//constr
    super(message);
  }//end constructor
}//end MyException class
```

Table 3.166

The constructor for this class receives an incoming **String** message parameter and passes it to the constructor for the superclass. This makes the message available for access by the **getMessage** method called in the catch block.

The try block

Listing 7 (p. 498) shows the beginning of the **main** method, including the entire **try** block

Listing 7 . The try block.

```
class Excep16{//controlling class
public static void main(
    String[] args){
  try{
    for(int cnt = 0; cnt < 5; cnt++){
      //Throw a custom exception, and
      // pass message when cnt == 3
      if(cnt == 3) throw
        new MyException("3");
      //Transfer control before
      // processing for cnt == 3
      System.out.println(
        "Processing data for cnt = "
          + cnt);
    }//end for-loop
  }//end try block
```

Table 3.167

The **main** method executes a **for** loop (*inside the **try** block*) that guarantees that the variable named **cnt** will reach a value of 3 after a couple of iterations.

Once during each iteration, (*until the value of **cnt** reaches 3*) a print statement inside the **for** loop displays the value of **cnt** . This results in the output shown in Figure 11 (p. 499) .

Figure 11 . Output from the for loop.

```
Processing data for cnt = 0
Processing data for cnt = 1
Processing data for cnt = 2
```

Table 3.168

What happens when **cnt** equals 3?

However, when the value of **cnt** equals 3, the **throw** statement in Listing 7 (p. 498) is executed. This causes control to transfer immediately to the matching **catch** block following the **try** block (*see Listing 8 (p. 499)*). During this iteration, the print statement following the **throw** statement is not executed. Therefore, the output never shows a value for **cnt** greater than 2, as shown in Figure 11 (p. 499) .

The catch block

Listing 8 (p. 499) shows a **catch** block whose type matches the type of exception thrown in Listing 7 (p. 498) .

Listing 8 . A matching catch block.

```
catch(MyException e){
System.out.println(
    "In exception handler, "
    + "get the message\n"
    + e.getMessage());
} //end catch block
```

Table 3.169

When the **throw** statement is executed in Listing 7 (p. 498) , control is transferred immediately to the **catch** block in Listing 8 (p. 499) . No further code is executed within the **try** block.

A reference to the object instantiated as the argument to the **throw** keyword in Listing 7 (p. 498) is passed as a parameter to the **catch** block. That reference is known locally by the name **e** inside the **catch** block.

Using the incoming parameter

The code in the **catch** block calls the method named **getMessage** (*inherited from the **Throwable** class*) on the incoming parameter and displays that message on the screen. This produces the output shown in Figure 12 (p. 500) .

Figure 12 . Output from the exception handler.

```
In exception handler, get the message

```

Table 3.170**When the catch block finishes execution ...**

When the code in the `catch` block has completed execution, control is transferred to the first executable statement following the `catch` block as shown in Listing 9 (p. 500) .

            "Out of catch block");

3.2.16.5 Summary

This module has covered many of the details having to do with exception handling in Java. By now, you should know that the use of exception handling is not optional in Java, and you should have a pretty good idea how to use exception handling in a beneficial way.

Along the way, the discussion has included the following topics:

- What is an exception?
- How do you throw and catch exceptions?
- What do you do with an exception once you have caught it?
- How do you make use of the exception class hierarchy provided by the Java development environment?

3.2.16.6 What's next?

That concludes the "Essence of OOP" portion of the ITSE 2321 sub-collection. The series is continued in the ITSE 2317 sub-collection.

Among other things, the Guzdial-Ericson multimedia class library makes it practical to write object-oriented programs for the manipulation of images in an interesting and educational way. For example, the image in Figure 1 (p. 504) was produced by manipulating and merging the images shown in Figure 2 (p. 505) and Figure 3 (p. 506) .

Figure 1 - Result of merging two images.

3.3.1.5 Discussion

The Guzdial-Ericson library was originally published by Guzdial and Ericson in conjunction with their book *Introduction to Computing and Programming with Java: A Multimedia Approach*¹⁶⁴. While the book isn't free, the library is freely available and is published under a Creative Commons Attribution 3.0 United States License¹⁶⁵.

As of July, 2012, the latest version of the library can be downloaded in a zip file named **bookClasses-3-9-10-with-doc.zip** at <http://home.cc.gatech.edu/TeaParty/47>.¹⁶⁶ Additional information is available at <http://coweb.cc.gatech.edu/mediaComp-plan/101>¹⁶⁷.

Download the library

In order to work with the programs in the modules that use the library, you will need to download a copy of the latest version of the library from the site listed above. To guard against the possibility of that link becoming broken at some point in the future, I am depositing a backup copy of the zip file containing the library on the cnx.org site and you can download it here¹⁶⁸.

Prepare the library for use

Once you have downloaded the zip file, you will need to extract the folder named **bookClasses** from the zip file and store it somewhere on your computer's disk.

Library documentation

¹⁶⁴<http://www.pearsonhighered.com/educator/academic/product/0,3110,0131496980,00.html>

¹⁶⁵<http://creativecommons.org/licenses/by/3.0/us/>

¹⁶⁶<http://home.cc.gatech.edu/TeaParty/47>.

¹⁶⁷<http://coweb.cc.gatech.edu/mediaComp-plan/101>

¹⁶⁸<http://cnx.org/content/m44148/latest/bookClasses-3-9-10-with-doc.zip>

When you examine the contents of the **bookClasses** folder, you will see that in addition to source code and compiled class files for the library, the folder also contains **javadoc** documentation for the library in a folder named **doc** and some other material as well. Go to the **doc** folder and open the file named **index.html** in your browser to view the documentation.

Put the library on the classpath

You will need to put the path to the **bookClasses** folder on your classpath in order to incorporate classes from the library into your programs.

Figure 4 . Putting the library on the classpath.

```
del *.class
javac -cp .;M:\bookClasses *.java
java -cp .;M:\bookClasses Prob01
```

Table 3.174

Figure 4 (p. 508) shows three commands that you can execute at a Windows command prompt to

- Delete the class files from the *current folder* or *current directory* – Google *current directory* if you don't recognize the term,
- Compile the source-code files in the *current folder* , and
- Execute the compiled version of a program named **Prob01** in the *current folder*

*The commands shown in Figure 4 (p. 508) assume that the **bookClasses** folder is in the root directory on the M-drive. The **bookClasses** folder will likely be in a different location on your computer. They also assume that you are compiling and running a program having its **main** method in a class named **Prob01** in a file named **Prob01.java** .*

Be sure to include the period and the semicolon shown before the **M** in Figure 4 (p. 508) . This tells the Java compiler and the Java Virtual Machine to search first in the *current folder* before searching elsewhere on the disk for the required files.

You can also put the three commands in a batch file and run the batch file to avoid having to type the three commands each time you need to compile and run the program. In that case, you should add a **pause** command following the other three commands.

*Note that this batch file must be placed in the same folder that contains the file named **Prob01.java** , and that folder must be your "current directory. **DO NOT** attempt to execute the commands shown in Figure 4 (p. 508) from inside the **bookClasses** folder."*

If you are using an IDE such as DrJava, JCreator, or JGrasp, see the instructions for the IDE to learn how to set the classpath in the IDE.

3.3.1.6 Two versions of Hello World

It is often useful to have the code for a simple program to test your system. This section presents two versions of the classical *Hello World* program. The first version is a simple text version that doesn't use Ericson's library. This version can be used to confirm that the Java Development Kit (JDK) is properly installed on your computer.

The second version is a graphic version that does require Ericson's library. This version can be used to confirm proper installation and use of the library.

3.3.1.6.1 A text version of Hello World

The simple program shown in Listing 1 (p. 509) causes the words **Text Hello World** to be displayed on the standard output device when the program is compiled and executed.

Listing 1 . A text version of Hello World.

```
class TextHelloWorld{
    public static void main(String[] args){
        System.out.println("Text Hello World");
    }//end main
}//end class
```

Table 3.175

As mentioned above, this program does not require the use of Ericson's library. It can be compiled and executed using a batch file containing the commands shown in Figure 5 (p. 509) . You should make certain that you can compile and execute this program before progressing to the graphic version.

*Note that this batch file must be placed in the same folder that contains the file named **TextHelloWorld.java** , and that folder must be your "current directory."*

Also note that the term "-cp ." (note the space followed by a period) is probably superfluous on most computers. According to `PATH` and `CLASSPATH` ¹⁶⁹ , "The default value of the classpath is "." (note the period), meaning that ..."

*Therefore, it should not be necessary to specify the classpath as "-cp ." to compile and execute the program on most computers. However, on 09/10/14, I encountered a student's computer that did not comply with the default described above and this prevented the student from being able to compile and execute the program. Including "-cp ." in the **javac** and **java** commands doesn't cause any harm. Therefore, I have updated the batch file commands shown in Figure 5 (p. 509) to include it. You can omit it if your computer doesn't need it.*

Figure 5 . Batch file for text version of Hello World.

```
echo off
del *.class
javac -cp . TextHelloWorld.java
java -cp . TextHelloWorld
pause
```

Table 3.176

3.3.1.6.2 A graphic version of Hello World

Listing 2 (p. 510) contains the code for a graphic version of Hello World.

¹⁶⁹<http://docs.oracle.com/javase/tutorial/essential/environment/paths.html>

Listing 2 . A graphic version of Hello World.

```
import java.awt.Color;

class GraphicHelloWorld{
    public static void main(String[] args){
        Picture pix = new Picture(200,100);
        pix.setAllPixelsToAColor(Color.RED);
        pix.addMessage("Graphic Hello World",15,50);
        pix.show();
    }// end main
} //end class
```

Table 3.177

The program shown in Listing 2 (p. 510) causes the image shown in Figure 6 (p. 510) to be displayed when the program is compiled and executed.

Figure 6 - Hello World in graphics.

As mentioned above, this program does require the use of Ericson's library. It can be compiled and executed using a batch file containing the commands shown in Figure 7 (p. 510) . You should make certain that you can compile and execute this program before progressing to more complex programs involving Ericson's library.

*Note that this batch file must be placed in the same folder that contains the file named **GraphicHelloWorld.java** , and that folder must be your "current directory."*

Figure 7 . Batch file for graphic version of Hello World. .

```
echo off

del *.class
javac -cp .;M:\bookClasses GraphicHelloWorld.java
java -cp .;M:\bookClasses GraphicHelloWorld
pause
```

Table 3.178

Once again, the commands shown in Figure 7 (p. 510) assume that the **bookClasses** folder is in the root directory on the M-drive. The **bookClasses** folder will likely be in a different location on your computer.

3.3.3.2 An alternative graphics library

Hopefully by now you have studied the lesson titled Java3000: The Guzdial-Ericson Multimedia Class Library¹⁸¹ and are completely familiar with the use of that library.

The Guzdial-Ericson Multimedia Class Library is an excellent library. However, it contains many classes, ranging from video to sound, that are not used in this course. This lesson provides a stripped-down alternative version of the Guzdial-Ericson library that eliminates classes that are not required for the course. This, in turn, results in a smaller documentation package that is much easier to navigate. In addition, the alternative library adds some features that are needed for assignments in more advanced courses.

Classes in this alternative graphics library were derived from classes in the multimedia library published by Barb Ericson at <http://home.cc.gatech.edu/TeaParty/47>¹⁸² in a downloadable file named **bookClasses-3-9-10-with-doc.zip**. A statement on that page reads as follows: *"The source code in bookClasses is licensed under a Creative Commons Attribution 3.0 United States License."*

¹⁷⁸This content is available online at <<http://cnx.org/content/m63525/1.2/>>.

¹⁷⁹<http://cnx.org/contents/dzOvxPFw>

¹⁸⁰http://cnx.org/contents/-2RmHFs_

¹⁸¹http://cnx.org/contents/dzOvxPFw:0xo_9JXz

¹⁸²<http://home.cc.gatech.edu/TeaParty/47>

You can download a copy of the alternative library by clicking here ¹⁸³. As with the Guzdial-Ericson library, simply extract the folder named `_altBookClasses` from the zip file, store it somewhere on your disk, and point to it with a classpath. Once you have done that, I recommend that you go back to Java3000: The Guzdial-Ericson Multimedia Class Library ¹⁸⁴ and recreate the graphic version of Hello World. Then compile and run it using the alternative library in place of the original Guzdial-Ericson library.

Once you have stored the folder named `_altBookClasses` on your disk, open it to find a folder named `docs`. Open that folder and locate a file named `index.html`. Open that file in your browser and you will find the documentation for about a dozen classes as compared to about five dozen classes in the original Guzdial-Ericson library. The classes in the alternative library are a subset of the classes in the original Guzdial-Ericson library, some with modifications as described below.

3.3.3.3 Modifications to the classes

As mentioned above, without changing the original functionality, modifications were made to some of the classes in the alternative library to add features that are useful in more advanced courses. Most of those modifications are described below.

3.3.3.3.1 The class named `Picture`

The use of the `DigitalPicture` interface was eliminated. It was only used by the `Picture` class among the subset of classes selected for this library and was therefore considered to be superfluous and confusing to students.

The `Picture` class and the `SimplePicture` class were collapsed into a single class named `Picture`. While possibly useful in some teaching situations, the use of inheritance in this case was considered to be superfluous and confusing to students.

The use of the media path was eliminated. While useful in some situations, the confusions and problems that it created among students developing on one machine and testing on a different machine outweighed the benefits.

The `addMessage` method was modified to cause it to use a color variable to set the color of the message to something other than the default white. This also required that a method named `setMessageColor` be defined to set the color and that a variable named `messageColor` be defined to contain the color.

3.3.3.3.2 The class named `PictureExplorer`

References to the `SoundExplorer` class were eliminated. This eliminated the requirement to include the `SoundExplorer` class in the alternative library.

As with the `Picture` class, the use of the `DigitalPicture` interface was eliminated and for the same reasons.

As with the `Picture` class, the use of the media path was eliminated and for the same reasons.

Accessor methods were added to cause the following values to be accessible from outside the object:

- `int xIndex`
- `int yIndex`
- `String rValue text`
- `String gValue text`
- `String bValue text`
- `double zoomFactor`
- `JFrame pictureFrame`

¹⁸³<http://cnx.org/content/m63525/latest/altBookClasses.zip>

¹⁸⁴http://cnx.org/contents/dzOvxPFw:0xo_9JXz

3.3.3.3.3 The class named `PictureFrame`

As with the `Picture` class, the use of the `DigitalPicture` interface was eliminated and for the same reasons

3.3.3.3.4 The class named `Pixel`

As with the `Picture` class, the use of the `DigitalPicture` interface was eliminated and for the same reasons.

3.3.3.3.5 The class named `Turtle`

The use of the `ModelDisplay` interface was eliminated by replacing `ModelDisplay` with `World`. The interface was only used by the `World` and `Turtle` classes among the subset of classes selected for this library and was therefore considered to be superfluous and confusing to students.

The `Turtle` class and the `SimpleTurtle` class were collapsed into a single class named `Turtle`. While possibly useful in some teaching situations, the use of inheritance in this case was considered to be superfluous and confusing to students.

3.3.3.3.6 The class named `World`

The implementation of the `ModelDisplay` interface by the `World` class was eliminated. The interface was only used by the `World` and `Turtle` classes among the subset of classes selected for this library and was therefore considered to be superfluous and confusing to students.

An accessor method named `getFrame` was added. The new method returns a reference to the `JFrame` object from which the `World` object is constructed.

The modified version of the `World` class makes it possible to specify the name of an image file when the `World` object is instantiated. The image is used as the background for the world in place of the default blank white background.

A call to the `setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE)` method was added to the method that initializes the frame to cause the program to terminate when the user clicks the X-button in the upper-right corner of the frame.

3.3.4.3 Preview

In this module, I will explain a program that uses Java and Ericson's media library to (see *Figure 1* (p. 523)) :

- Add a picture and two turtles to a world.
- Manipulate the turtles, their colors, and their pens.

Stated in more detail, the program will:

- Create a **Picture** object from an image file and replace the default white **Picture** in a **World** object with the new **Picture** object.
- Place two **Turtle** objects in a **World** object.
- Apply a series of operations to manipulate the two turtle objects so as to produce a specific graphic output.
- Provide accessor methods to get references to two **Turtle** objects and the **World** object.
- Use the references to get information from the **World** and **Turtle** objects and display that information on the command-line screen.
- Display text on a **Picture** in a **World** object.

Program output

Figure 1 (p. 523) shows the graphic screen output produced by this program.

3.3.4.4 Discussion and sample code

Will explain in fragments

I will explain this program in fragments. A complete listing of the program is provided in Listing 9 (p. 541) near the end of the module.

I will begin with the driver class named **Prob01** , which is shown in its entirety in Listing 1 (p. 525) .

Listing 1 . The driver class.

```
import java.awt.Color;

public class Prob01{//Driver class
    public static void main(String[] args){
        //Instantiate an object and call its method named run.
        Prob01Runner obj = new Prob01Runner();
        obj.run();

        //Get information from the object and display it on
        // the command-line screen.
        System.out.println(obj.getMars());
        System.out.println(obj.getJoe());
        System.out.println(obj.getSue());
    }//end main
} //end class Prob01
```

Table 3.185

The import directive

Note the *import directive* at the very beginning of Listing 1 (p. 525) . This is a directive to the compiler and the virtual machine notifying them that the class named **Color** can be found in the package named **java.awt** .

What is a package?

Boiled down to its simplest description, a package is nothing more than the specification of a particular folder on the disk relative to a standard root folder. (*Think of it as a disk-path specification with the periods representing \ characters on a Windows machine and representing / characters on a Unix machine.*)

The public class named Prob01

Every Java application (*not true for Java applets*) must include the definition of a class that contains the definition of a method named **main** with a method signature having the syntax shown in Listing 1 (p. 525) .

The name of the class/application

The name of the class containing the **main** method is also the name of the application insofar as being able to compile and execute the application is concerned. In this case, the name of the class, and hence the name of the application is **Prob01** .

Source code file name

The name of the source code file containing this class must match the name of the class. In this case, the source code file must be named **Prob01.java** . (*Note the .java extension.*)

Compiling the application

In its simplest form, this application can be compiled by executing the following command at the command prompt:

```
javac Prob01.java
```

Note however that it is often necessary to specify the path to various library files on the command line when compiling the application. In that case, the simplest form given above is not sufficient.

Compiler output file names

When the application is successfully compiled, it will produce one or more output files with an extension of `.class`. In this case, one of those files will be named `Prob01.class`.

Execution of the application

The execution of C and C++ programs begins and ends in the `main` function. The execution of Java applications begin and end in the method named `main`.

Once again, in its simplest form, this application can be executed by entering the following command at the command prompt:

```
java Prob01
```

Again, it is often necessary to specify the path to various library files on the command line when executing the application. In that case, the simplest form is not sufficient.

Compilation and execution on my machine

This application can be compiled and executed on my machine by entering the two commands shown in Figure 3 (p. 526) at the command prompt. *(Note that artificial line breaks were inserted into Figure 3 (p. 526) to force the long commands to fit this narrow format.)*

Figure 3 . Commands to compile and execute the application.

```
javac -cp .;M:\Baldwin\AA-School\Itse2321Intro00P\
MediaCompBookMaterial\bookClasses Prob01.java

java -cp .;M:\Baldwin\AA-School\Itse2321Intro00P\
MediaCompBookMaterial\bookClasses Prob01
```

Table 3.186

The compiler and the virtual machine

The `javac` portion of the first command causes the Java compiler to run.

The `java` portion of the second command causes the Java virtual machine to run.

The input files

The `Prob01.java` and `Prob01` at the ends of the two commands specify the files being operated on by the compiler and the virtual machine respectively.

A classpath

In both cases, the `-cp` indicates that a classpath follows.

A classpath consists of one or more path specifications separated by semicolon characters.

The purpose of the classpath is to tell the compiler and the virtual machine where to look for previously compiled class files that the application needs in order to successfully compile and execute.

The current folder

The period ahead of the semicolon says to search the current folder first.

The path to the Ericson library

The material following the semicolon is the absolute path to the folder containing the class files that make up Ericson's library on my machine. The location of that folder will probably be different on your machine.

The main method

Now that we have the preliminaries out of the way, let's go back and examine the body of the main method in Listing 1 (p. 525) .

The first statement in the body of the main method in Listing 1 (p. 525) instantiates a new object of the class named **Prob01Runner** .

The statement saves a reference to that object in a reference variable named **obj** . Note that the type of the variable is the same as the name of the class in this case. In general, the type of the variable must be:

- The name of the class, or
- The name of a superclass of the class, or
- The name of an interface implemented by the class.

Accessing the object

You must save a reference to an object in order to gain access to the object later. In this case, the reference is stored in the variable named **obj** .

Call the method named run

The second statement in the body of the **main** method in Listing 1 (p. 525) uses that reference to call the method named **run** encapsulated in the object. As you will see later, most of the work in this application is performed in the method named **run** .

Get and display information about the object

When the **run** method returns control to the **main** method, the last three statements in the body of the **main** method in Listing 1 (p. 525) use the object's reference to call the following three methods belonging to the object:

- getMars
- getJoe
- getSue

Accessor methods

These three methods are of a type that is commonly referred to as *accessor methods* . They access and return values encapsulated inside an object. In most cases, (*using good programming practice*) they return copies of the values. This protects the encapsulated values from being corrupted by code outside the object.

The method named println

In each case in Listing 1 (p. 525) , the value returned by the method is passed to a method named **println** . This is a method belonging to a standard system object that represents the standard output device (*usually the command-line screen*) . The purpose of the **println** method is to display material on the command-line screen.

System.out.println...

Without going into detail about how this works, you should simply memorize the syntax of the last three statements in the body of the **main** method in Listing 1 (p. 525) . If you are interested in learning more on this topic, I explain the concepts involved in some detail here ¹⁹² and here ¹⁹³ .

This code (*System.out.println...*) provides the mechanism by which you can display material on the command line screen in a running Java application. The last three statements in the main method in Listing 1 (p. 525) produced the last three lines of text in Figure 2 (p. 524) .

(*Note that only the last four lines of text in Figure 2 (p. 524) (p. 524) were produced by the program. Everything above that was produced by the system during the compilation and initial execution of the application.*)

What do you know so far?

So far, you know the following to be true:

- The program instantiates an object of the class named **Prob01Runner** .

¹⁹²<http://cnx.org/content/EHRr6hjR:WAqpwja>

¹⁹³<http://cnx.org/content/EHRr6hjR:kAoIyWcB>

- The program causes a method named **run** belonging to that object to be executed.
- When the **run** method returns, the program calls three accessor methods in succession, causing the values returned by those methods to be displayed on the command-line screen.
- The fourth line of text from the bottom in Figure 2 (p. 524) (*Dick Baldwin*) was produced before the last three lines of text discussed above. Therefore, that line of text must have been produced before control reached the call to the **getMars** method in Listing 1 (p. 525) .

The public modifier

Java uses four access modifiers to specify the accessibility of various classes and members in a Java application:

- public
- private
- protected
- package-private

Rather than trying to explain all four at this time, I will explain **public** here and explain the other three when we encounter them in code.

The **public** modifier is the easiest of the four to explain. As the name implies, it is analogous to a public telephone. Any code that can find a class or class member with a public modifier can access and use it. In this case, any code that can find the class definition for the class named **Prob01** can instantiate an object of that class.

The class named Prob01Runner

There's not a lot more that we can say about the driver class named **Prob01** , so it's time to analyze the class named **Prob01Runner** . We need to figure out what it is about that class that causes the program output to match the material shown in Figure 1 (p. 523) and Figure 2 (p. 524) .

Beginning of the class named Prob01Runner

The definition of the class named **Prob01Runner** begins in Listing 2 (p. 528) .

Listing 2 . Beginning of the class named Prob01Runner.

```
class Prob01Runner{
//Instantiate the World and Turtle objects.
private World mars = new World(300,274);
private Turtle joe = new Turtle(mars);
private Turtle sue = new Turtle(mars);
```

Table 3.187

No access modifier

Note that this class definition does not have an access modifier such as **public** , **private** , or **protected** . This puts it in **package-private** access category.

The lack of an access modifier causes a class to be put in the **package-private** access category. A class with package-private access can be accessed by code that is stored in the same package and cannot be accessed by code stored in other packages.

Three private variables

The last three statements in Listing 2 (p. 528) declare three private variables. Because these variables are declared **private** , they can only be accessed by code contained in methods defined inside the class.

They are also accessible by code contained in methods defined in classes defined inside the class, but that is beyond the scope of this module.

Three private instance variables

These variables are also *instance variables* as opposed to *class variables* . (We will discuss class variables in a future module.)

Because they are instance variables, they belong to an object instantiated from the class. (An object is an instance of a class.) Even if the variables were public, they could only be accessed by first gaining access to the object to which they belong.

Multiple instances of the class

If you instantiate multiple objects of this same class (create multiple instances which you often do) , each object will encapsulate the same set of the three private instance variables shown in Listing 2 (p. 528) . Instance variables have the same name but may have different values in the different objects.

Three private instance reference variables

The three variables declared in Listing 2 (p. 528) are also *reference variables* (as opposed to *primitive variables*) . This means that they are capable of storing references to objects as opposed to simply being able to store primitive values of the following eight types:

- char
- byte
- short
- int
- long
- float
- double
- boolean

Primitive variables can only store primitive values of the types in the above list.

Classes, classes, and more classes

A Java application consists almost exclusively of objects. Objects are instances of classes. Therefore, class definitions must exist before objects can exist.

The true power of Java

The Java programming language is small and compact. The true power of Java lies in its libraries of predefined classes.

The Java standard edition development kit and runtime engine available from Oracle contains a library consisting of thousands of predefined classes. Other class libraries containing thousands of classes are available from Oracle in the enterprise edition and the micro edition.

Non-standard class libraries

In some cases, you or your company may create your own class libraries and/or obtain class libraries from other sources such as the Ericson class library that we are using in this module.

Custom class definitions

In almost all cases, you will need to define a few new classes for new applications that you write. We will define two new classes for this application. The remainder of the classes that we use will come either from Oracle's standard library or Ericson's library.

Objects of the World class and the Turtle class

Ericson's class library contains a class named **World** and another class named **Turtle** . The code in Listing 2 (p. 528) instantiates one object of the **World** class and populates that world with two objects of the **Turtle** class.

Every class has a constructor

Every class definition has one or more method-like members called constructors. (If you don't define a constructor when you define a class, a default constructor will be automatically defined for your class.)

The name of the constructor must always be the same as the name of the class. Like a method, a constructor may or may not take arguments. If there are two or more (*overloaded*) constructors, they must have different argument lists.

Instantiating an object of a class

To instantiate an object of a class, you apply the **new** operator (see *Listing 2 (p. 528)* (p. 528)) to the class' constructor, passing parameters that satisfy the required arguments for the constructor.

Return a reference to the object

Once the object has been instantiated, the constructor returns a reference to the new object.

A new World object

For example, the first statement in *Listing 2 (p. 528)* applies the **new** operator to Ericson's **World** class constructor passing two integer values as parameters. This causes a new **World** object to be instantiated.

A reference is returned

A reference to the new **World** object is returned and stored in the reference variable named **mars** .

Once the reference is stored in the reference variable, it can be used to access the **World** object later.

Constructors for the World class

Figure 4 (p. 530) shows the overloaded constructors that are available for Ericson's **World** class. (See *javdocs for the Ericson library.*)

Figure 4 (p. 530) - Constructors for the World class.

Constructor Summary	
World()	Constructor that takes no arguments
World(boolean visibleFlag)	Constructor that takes a boolean to say if this world should be visible or not
World(int w, int h)	Constructor that takes a width and height for this world

A new World object

The third constructor in *Figure 4 (p. 530)* was used to construct a **World** object in *Listing 2 (p. 528)* with a width of 300 pixels and a height of 274 pixels. As explained earlier, this object's reference was saved in the variable named **mars** .

Two new Turtle objects

The last two statements in *Listing 2 (p. 528)* instantiate two objects of the **Turtle** class and use them to populate the **World** object whose reference is stored in the variable named **mars** .

More complicated than before

This is a little more complicated than the instantiation of the **World** object. Ericson's javadocs indicate that the **Turtle** class provides the four overloaded constructors shown in *Figure 5 (p. 530)* .

Figure 5 (p. 530) - Constructors for the Turtle class.

Constructor Summary
Turtle(int x, int y, ModelDisplay modelDisplayer) Constructor that takes the x and y and a model display to draw it on
Turtle(int x, int y, Picture picture) Constructor that takes the x and y and a picture to draw on
Turtle(ModelDisplay modelDisplay) Constructor that takes the model display
Turtle(Picture p) Constructor that takes a picture to draw on

A World object as a parameter

If you dig deep enough, and if you study Ericson's textbook, you can determine that the third constructor in Figure 5 (p. 530) will accept a reference to a **World** object as a parameter. This is the constructor that was used in the last two statements in Listing 2 (p. 528) .

ModelDisplay interface The World class implements the ModelDisplay interface. Therefore, an object of the World class can be treated as it is type ModelDisplay. I explain the relationship between classes and interfaces here ¹⁹⁴ and here ¹⁹⁵ .

Displayed in the center of the world

When the two **Turtle** objects instantiated in Listing 2 (p. 528) come into existence, they will be displayed in the center of the **World** object referred to by the contents of the variable named **mars** . However, that happens so quickly that you probably won't see it when you run this program.

Eliminating the run method call

If you were to eliminate the call to the **run** method in Listing 1 (p. 525) , you would see a world with a white background and a single turtle positioned in the center of the world facing north. There would actually be two turtles there, but they would be in exactly the same location so only the one closest to you would be visible.

The constructor for the Prob01Runner class

That's probably enough discussion of the three statements in Listing 2 (p. 528) . The constructor for the class named **Prob01Runner** is shown in its entirety in Listing 3 (p. 531) .

Listing 3 . The constructor for the Prob01Runner class.

```
public Prob01Runner(){//constructor
    System.out.println("Dick Baldwin.");
} //end constructor
```

Table 3.188

¹⁹⁴<http://cnx.org/contents/dzOvxPFw:LAUK4UwQ>

¹⁹⁵<http://cnx.org/contents/1CVBGBJj:-rp3xIXO>

The purpose of constructors

The primary purpose for which constructors exist is to assist in the initialization of the variables belonging to the object being constructed. However, it is possible to directly initialize the variables as shown in Listing 2 (p. 528) .

Initialization of variables

When an object comes into existence, the variables belonging to that object will have been initialized by any direct initializers like those shown in Listing 2 (p. 528) as well any initialization produced by code written into the constructor.

Default initialization

If a variable (*exclusive of local variables inside of methods*) is not initialized in one of those two ways, it will receive a default initialization value. The default values are:

- 0 or 0.0 for numeric variables
- false for boolean variables
- null for reference variables

Non-initialization code in constructors

Although it is usually not good programming practice to do so, there is no technical reason that you can't write code into the constructor that has nothing to do with variable initialization. Such code will be executed when the object is instantiated.

An object counter

For example, you might need to keep track of the number of objects that are instantiated from a particular class, such as the total number of asteroid objects in a game program for example You could write the code to do the counting in the constructor.

Display my name

The code in the constructor in Listing 3 (p. 531) simply causes my name to be displayed on the command-line screen when the object is instantiated. That is how my name appears ahead of the other lines of output text in Figure 2 (p. 524) . My name is displayed when the object is instantiated. The remaining three lines of text in Figure 2 (p. 524) are displayed later by manipulating the object.

Three accessor methods

Listing 4 (p. 532) defines three accessor methods that are used to access and return copies of the contents of the private instance variables named `joe` , `sue` , and `mars` .

Listing 4 . Three accessor methods.

```
public Turtle getJoe(){return joe;}
public Turtle getSue(){return sue;}
public World getMars(){return mars;}
```

Table 3.189**Good OOP practice**

Good object-oriented programming practice says that most of the instance variables encapsulated in an object should be declared private. If there is a need to make the contents of those variables available outside the object, that should be accomplished by defining public accessor methods. (*Accessor methods are often referred to as getter methods because the name of the accessor method often includes the word "get".*)

Setter methods

If there is a need for code outside the object to store information in the object's private instance variables, this should be accomplished by writing public *setter* methods. Code in the setter methods can filter incoming data to make certain that the state of the object doesn't become corrupt as a result of outside influences.

Pass and return by value

Everything in Java is passed and returned *by value* , not by reference.

Each of the accessor methods shown in Listing 4 (p. 532) returns a copy of the reference belonging to either a **Turtle** object or a **World** object.

Pass to the println method

As you saw earlier, each of the three references is passed to the `println` method in Listing 1 (p. 525) causing information about the objects to be displayed on the command-line screen.

The toString method

Although it isn't obvious in Listing 1 (p. 525) , the code in the `println` method calls a method named `toString` on the incoming object reference and displays the string value returned by that method. I discuss the `toString` method in some detail here ¹⁹⁶ and here ¹⁹⁷ .

An overridden method

The `toString` method is overridden (*not overloaded*) in the **World** and **Turtle** classes so as to return a string value describing the object.

The Ericson javadocs

Normally, the javadocs would tell you what information is contained in that string, but that is not the case in Ericson's javadocs. You would have to get into her source code, (*which is readily available*), to get that information. However, you can see the information that is contained in the string values for the two different types of objects in the last three lines of text in Figure 2 (p. 524) .

The beginning of the run method

This is where things start to get interesting. Listing 5 (p. 533) shows the beginning of the `public` method named `run` .

Listing 5. The beginning of the run method.

```
public void run(){
//Replace the default all-white picture with another
// picture.
mars.setPicture(new Picture("Prob01.jpg"));
```

Table 3.190

Recall that the code in the `main` method in Listing 1 (p. 525) calls the `run` method on the object immediately after it is instantiated.

A turtle on a white background

I told you earlier that if you were to eliminate the call to the `run` method, you would see a turtle at the center of the world with a white background.

The background is a Picture object

The background of a **World** object consists of an object of Ericson's **Picture** class. (*A **Picture** object is encapsulated in the **World** object.*)

By default, the **Picture** object encapsulated in a **World** object is all white and is exactly the right size and shape to completely fill the area inside the world's border (*see Figure 1 (p. 523) (p. 523)*).

Can be replaced

As you will see shortly, we can replace the default **Picture** object with a new **Picture** object of our own choosing.

What if it doesn't fit?

¹⁹⁶<http://cnx.org/content/EHRr6hjR:Fg0-bUk3>

¹⁹⁷<http://cnx.org/content/dzOvxPFw:ch9iAGEJ>

If the new **Picture** object isn't large enough to completely fill the area inside the borders of the **World** object, it will be placed in the upper-left corner of the **World** object and the remainder of the **World** object will be a light gray color.

If the **Picture** object is too large, an upper-left rectangular portion of the **Picture** object, sufficient to fill the **World** object, will be displayed. The remainder of the **Picture** object will not be visible even if you manually resize the **World** object to make it larger.

Constructors for the **Picture** class

Figure 6 (p. 534) shows the javadocs for the constructors for Ericson's **Picture** class.

Figure 6 (p. 534) - Constructors for the **Picture class.**

Constructor Summary	
Picture()	Constructor that takes no arguments
Picture(BufferedImage image)	Constructor that takes a buffered image
Picture(int width, int height)	Constructor that takes the width and height
Picture(Picture copyPicture)	Constructor that takes a picture and creates a copy of that picture
Picture(String fileName)	Constructor that takes a file name and creates the picture

Replace the default picture object

The right-hand portion of the last statement in Listing 5 (p. 533) uses the last constructor in Figure 6 (p. 534) to instantiate a new **Picture** object that encapsulates the image contained in the image file named **Prob01.jpg** .

(Click [here](#)¹⁹⁸ to download a copy of the file named *Prob01.jpg*.)

What about the size of the **Picture** object?

I was careful to use an image that was a little wider than and exactly as tall as the dimensions of my **World** object (300 x 274) . Therefore, the image completely filled the world as shown in Figure 1 (p. 523) .

Pass the reference to a setter method

The reference belonging to the new **Picture** object was passed to the **setPicture** method of the **World** object (a *setter method*) in Listing 5. (p. 533) This caused the new picture containing the penguin to replace the default all-white picture that forms the background for the **World** object. (See Figure 1 (p. 523) .)

A subclass of the **SimplePicture** class

Ericson's **Picture** class is a subclass of (extends) the class named **SimplePicture** . Therefore, an object of the **Picture** class encapsulates all of the methods defined in the **Picture** class in addition to all of the methods defined in the **SimplePicture** class.

A subclass of the **Object** class

¹⁹⁸<http://cnx.org/content/m44149/latest/Prob01.jpg>

Further, the **SimplePicture** class is a subclass of (*extends*) the **Object** class. Therefore, an object of the **Picture** class also encapsulates all of the methods defined in the **Object** class.

The AddMessage method

One of the methods defined in the **SimplePicture** class and inherited into the **Picture** class is named **AddMessage** .

The **addMessage** method requires three parameters:

- a string and
- two coordinate values of type **int** .

The **addMessage** method will draw the string as text characters onto the image at the location specified by the two coordinate values.

(The origin of the coordinate system is the upper-left corner of the image with positive horizontal values going to the right and positive vertical values going down.)

Add text to the image

The code in Listing 6 (p. 535) uses two levels of indirection to add my name as a message to the picture that forms the background of the world as shown in Figure 1 (p. 523) .

Listing 6 . Add text to the image.

```

mars.getPicture().addMessage(
    "Dick Baldwin",10,20);

```

Table 3.191

Get and access the World object

To begin with, Listing 6 (p. 535) goes to the variable named **mars** to get a reference to the **World** object. This reference is used to access the **World** object.

Access the Picture object via a getter method

Then the code in Listing 6 (p. 535) calls the getter method named **getPicture** to gain access to the **Picture** object encapsulated in the **World** object.

Call the addMessage method

Having gained access to the **Picture** object, Listing 6 (p. 535) calls the **addMessage** method on that object passing my name as a **String** object along with a pair of coordinate values that specify a location near the upper-left corner of the image. The result is that my name appears in the world as shown in Figure 1 (p. 523) .

Methods encapsulated in the Turtle object

The **Turtle** class extends the **SimpleTurtle** class, which in turn extends the **Object** class. Therefore, an object of the **Turtle** class encapsulates all of the methods defined in all three classes.

Manipulate the turtle referred to by the variable named joe

A **Turtle** object encapsulates many methods that can be used to manipulate the turtle in a variety of different ways. This is illustrated by the series of statements in Listing 7 (p. 536) .

Listing 7 . Manipulate the turtle named joe.

```

    joe.setName("joe");

    joe.setBodyColor(Color.RED);
    joe.setShellColor(Color.BLUE);

    joe.setPenColor(Color.YELLOW);
    joe.setPenWidth(3);

    joe.forward();

    joe.turn(-135);
    joe.setPenColor(Color.BLUE);
    joe.forward(150);

```

Table 3.192**Initial (default) state of a Turtle object**

When a new **Turtle** object is instantiated and added to a **World** object (*using the constructor shown in Listing 2 (p. 528)*), it doesn't have a name property.

The turtle initially appears in the center of the world, facing north with a default color.

Every **Turtle** object has a pen attached to its belly that can draw a line with a default width of one pixel in a default color when the turtle moves.

The pen can be raised so that it won't draw a line or lowered so that it will draw a line. Initially it is down and will draw a line by default.

Set the name property to "joe"

Listing 7 (p. 536) begins by setting the name property of one of the turtles to the string value "joe."

*Note that this is completely independent of the fact that a reference to this turtle is stored in a variable named **joe**. The name property could have been set to "Tom", "Dick", "Harry", or any other string value. It is the value of the name property and not the name of the variable that determines the text output shown in Figure 2 (p. 524).*

Set the turtle's body and shell color

Listing 7 (p. 536) continues by calling two *setter* methods on the turtle object to set the body color (*head and feet*) to red and the color of the shell to blue. You can see the effect of this in Figure 1 (p. 523).

Set the pen color and width

Then Listing 7 (p. 536) calls two *setter* methods that set the turtle's pen color to yellow and the pen width to three pixels. You can also see the result of this in Figure 1 (p. 523).

Make the turtle move forward

After that, Listing 7 (p. 536) calls the **forward** method (*with no parameters*) to cause the turtle to move forward by a default distance of 100 pixels.

Recall that the turtle initially faces north. In this case, the forward method causes the turtle to move from the center of the world to a location that is 100 pixels due north of the center of the world, drawing a wide yellow line along the way.

Turn counter clockwise

Then Listing 7 (p. 536) calls the **turn** method causing the turtle to rotate its body by 135 degrees counter-clockwise. (*A positive parameter causes a clockwise rotation and a negative parameter causes a counter clockwise rotation.*)

Change the pen color and move forward again

Finally Listing 7 (p. 536) calls methods to change the pen color to blue and to cause the turtle to move forward by 150 pixels.

The final location

After making the turn, the turtle is facing southwest. Therefore, the forward movement causes a diagonal blue line to be drawn from the position at the top of the yellow line down toward the southwest. As you can see in Figure 1 (p. 523), the turtle comes to rest at the end of that line.

A few words about color

I have published extensively on the concept of color in Java. The best way to find that information is probably to go to Google and search for the keywords:

```
richard baldwin "color class" site:http://cnx.org/contents/
```

Google is also probably your best bet for finding information on other topics that I have published on various websites. For example, if you go to Google Images ¹⁹⁹ and search for the following keywords, you will find a lot of the work that I have published using Ericson's media library.

```
richard baldwin java ericson
```

Manipulate the turtle named sue

Listing 8 (p. 537) calls several methods on the object whose reference is stored in the variable named `sue`.

Listing 8 . Manipulate the turtle named sue.

```
sue.setName("sue");

sue.setPenWidth(2);
sue.setPenColor(Color.RED);

sue.moveTo(183,170);
sue.setPenDown(false);

sue.moveTo(216,203);
sue.setPenDown(true);

sue.moveTo(250,237);
} //end run method
} //end class Prob01Runner
```

Table 3.193

The end result

These method calls result in the turtle named `sue` facing north in the lower right corner of the window, having drawn the broken red line shown in Figure 1 (p. 523) in getting there.

The moveTo method

Listing 8 (p. 537) calls the `moveTo` method to cause the turtle to move to a new location on the basis of coordinate values instead of on the basis of a distance value.

¹⁹⁹<https://images.google.com/>

Pen control

Listing 8 (p. 537) also calls the `setPenDown` method twice passing false and then true as the parameter to first raise and then lower the pen. This produced the gap in the red line shown in Figure 1 (p. 523).

The `Turtle` class also provides methods named `penUp` and `penDown` that can be used to raise and lower the pen.

The end of the program

Listing 8 (p. 537) also signals the end of the method named `run` and the end of the class named `Prob01Runner`. As such, Listing 8 (p. 537) signals the end of the program.

3.3.4.5 Run the program

I encourage you to copy the code from Listing 9 (p. 541), compile it and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

3.3.4.6 Summary

I explained a program that uses Java and Ericson's media library to:

- Add a picture and two turtles to a world.
- Manipulate the turtles, their color, and their pens.

Stated in more detail, the program:

- Creates a `Picture` object and replaces the default white `Picture` in a `World` object with the new `Picture` object.
- Places two `Turtle` objects in a `World` object.
- Applies a series of operations to manipulate the two turtle objects so as to produce a specific graphic output.
- Provides accessor methods to get references to two `Turtle` objects and the `World` object.
- Gets information from the `World` and `Turtle` objects and displays the information on the command-line screen.
- Displays text on a `Picture` in a `World` object.

3.3.4.7 What's next?

In the next module, I will teach you how to invert images and how to display images using Ericson's `PictureExplorer` object.

Answer 19 (p. 558)

3.3.5.3.20 Question 20

True or False? The first statement in Listing 1 (p. 544) saves a reference to a new object of the class named **Prob01Runner** in a reference variable named **obj** . In general, the type of the variable must be:

- The name of the object, or
- The name of a superclass of the object, or
- The name of an interface implemented by the object.

Answer 20 (p. 558)

3.3.5.3.21 Question 21

True or False? In Java, you must save a reference to a newly instantiated object in order to gain access to that object later in the program.

Answer 21 (p. 558)

3.3.5.3.22 Question 22

True or False? The second statement in the body of the **main** method in Listing 1 (p. 544) uses the reference stored in the variable named **obj** to call the method named **run** encapsulated in the object referred to by the contents of **obj** .

3.3.5.3.23 Question 23

True or False? The following three methods that are called in Listing 1 (p. 544) are of a type that is commonly referred to as *accessor methods* . They are also sometimes referred to by the slang term *getter methods* .

- `getSue`

Answer 23 (p. 558)

3.3.5.3.24 Question 24

3.3.5.3.25 Question 25

True or False? Java uses four access modifiers to specify the accessibility of various classes and members in a Java application:

- `public`
- `private`
- `protected`
- `package-private`

Answer 25 (p. 557)

3.3.5.3.26 Question 26

True or False? Listing 5 (p. 549) shows the beginning of a class named **Prob01Runner** .

//Instantiate the World and Turtle objects.
private World mars = new World(300,274);
private Turtle joe = new Turtle(mars);
private Turtle sue = new Turtle(mars);

```

Table 3.198

Answer 26 (p. 557)

3.3.5.3.27 Question 27

True or False? The class that begins in Listing 5 (p. 549) does not have an access modifier. This puts it in **package-private** access category. A class with package-private access can be accessed by code that is stored in the same package and cannot be accessed by code stored in other packages.

Answer 27 (p. 557)

3.3.5.3.28 Question 28

True or False? The last three statements in Listing 5 (p. 549) declare three **private** variables. Because these variables are declared private, they can be accessed by any method defined in any class in the same package.

Answer 28 (p. 557)

3.3.5.3.29 Question 29

True or False? The three variables declared in Listing 5 (p. 549) are *instance variables* as opposed to *class variables* .

Answer 29 (p. 557)

3.3.5.3.30 Question 30

True or False? Because the three variables declared in Listing 5 (p. 549) are instance variables, they belong to an object instantiated from the class. Even if the variables were public, they could only be accessed by first gaining access to the object to which they belong.

Answer 30 (p. 557)

3.3.5.3.31 Question 31

True or False? The three variables declared in Listing 5 (p. 549) are *reference variables* . This means that they are capable of storing references to objects and are also capable of storing values of the eight primitive types.

Answer 31 (p. 557)

3.3.5.3.32 Question 32

True or False? Ericson's class library contains a class named **World** and another class named **Turtle** . The code in Listing 5 (p. 549) instantiates one object of the **World** class and populates that world with three objects of the **Turtle** class.

Answer 32 (p. 557)

3.3.5.3.33 Question 33

True or False? Every class definition has one or more method-like members called constructors. (*If you don't define a constructor when you define a class, a default constructor will be automatically defined for your class.*)

Answer 33 (p. 556)

3.3.5.3.34 Question 34

True or False? The name of the constructor must always be the same as the name of the class in which it is defined. Like a method, a constructor may or may not take arguments. If there are two or more (*overloaded*) constructors, they must have different argument lists.

Answer 34 (p. 556)

3.3.5.3.35 Question 35

True or False? To instantiate an object of a class, you apply the **new** operator to the class' constructor, passing parameters that satisfy the required arguments for the constructor.

Answer 35 (p. 556)

3.3.5.3.36 Question 36

True or False? When an object is instantiated, the constructor returns an array containing the values in all of the instance variables.

Answer 36 (p. 556)

3.3.5.3.37 Question 37

True or False? The last two statements in Listing 5 (p. 549) instantiate two objects of the **Turtle** class and use them to populate the **World** object whose reference is stored in the variable named **mars** .

Answer 37 (p. 556)

3.3.5.3.38 Question 38

True or False? If a variable (*exclusive of local variables inside of methods*) is not purposely initialized when the object is instantiated, it will receive a default initialization value. The default values are:

- 0 or 0.0 for numeric variables
- true for boolean variables
- null for reference variables

Answer 38 (p. 556)

3.3.5.3.39 Question 39

True or False? Code written into a class' constructor is executed when an object of the class is instantiated.

Answer 39 (p. 556)

3.3.5.3.40 Question 40

True or False? Good object-oriented programming practice says that most of the instance variables encapsulated in an object should be declared private. If there is a need to make the contents of those variables available outside the object, that should be accomplished by defining protected accessor methods.

Answer 40 (p. 556)

3.3.5.3.41 Question 41

True or False? Everything in Java is passed and returned by reference.

Answer 41 (p. 556)

3.3.5.3.42 Question 42

True or False? Each of the accessor methods shown in Listing 6 (p. 551) returns a copy of the reference pointing to either a **Turtle** object or a **World** object.

Listing 6 . Question 42.

```
public Turtle getJoe(){return joe;}
public Turtle getSue(){return sue;}
public World getMars(){return mars;}
```

Table 3.199

Answer 42 (p. 556)

3.3.5.3.43 Question 43

True or False? Code in the **println** method calls a method named **toString** on each incoming primitive value and displays the string value returned by that method.

Answer 43 (p. 555)

3.3.5.3.44 Question 44

True or False? The **toString** method is overridden (*not overloaded*) in the **World** and **Turtle** classes so as to return a string value describing the object.

Answer 44 (p. 555)

3.3.5.3.45 Question 45

True or False? The code in Listing 7 (p. 551) replaces the default all-white picture in a **World** object with another picture. (*Note, the variable named **mars** contains a reference to an object of the class **World**.*)

Listing 7 . Question 45.

```
public void run(){
mars.setPicture(new Picture("Prob01.jpg"));
```

3.3.5.3.46 Question 46

True or False? The background of a **World** object consists of an object of Ericson's **Picture** class. (A **Picture** object is encapsulated in the **World** object.)

Answer 46 (p. 555)

3.3.5.3.47 Question 47

True or False? The code in Listing 8 (p. 552) uses two levels of indirection to add my name to the picture that forms the background of the world shown in Figure 1 (p. 552) .

Listing 8 . Question 47.

Answer 48 (p. 555)

3.3.5.3.49 Question 49

True or False? A call to the **forward** method of a **turtle** object with no parameters causes the turtle to move forward by a default distance of 100 pixels.

Answer 49 (p. 555)

3.3.5.3.50 Question 50

True or False? A call to the **moveTo** method of a **turtle** object with a single parameter value of 150 causes the turtle to move forward by a distance of 150 pixels.

3.3.6.3 Preview

In this lesson, I will explain programs that use a **Turtle** object to graph the following mathematical functions:

- A straight line
- A parabola
- A cubic
- A circle (*two approaches*)
- A cosine

I will also show you how to graph a circle and a line without using a **Turtle** object and compare the two approaches.

3.3.6.4 General background information

You learned about the **World** class, the **Turtle** class, and the **Picture** class in an earlier lesson titled Java3002: Creating and Manipulating Turtles and Pictures in a World Object ²²³ . You learned the fundamentals of causing the turtle to move and to draw a line with different colors and different line widths in the process. For review, Figure 1 (p. 563) shows an image that you learned to create in that earlier lesson.

Figure 1. Two turtles in a World object.

²²³<http://cnx.org/contents/dzOvxPFw:WpmhN38H>

In comparison, Figure 2 (p. 565) shows the sort of thing that you will learn to do in this lesson.

Figure 2. Graph of a cubic function.

The blue line in Figure 2 (p. 565) shows a graph of the following cubic function in a Cartesian coordinate system:

$$y = x*x*x$$

The red lines in Figure 2 (p. 565) show the x and y axes.

The graph in Figure 2 (p. 565) was created by computing the x and y coordinate values (*points*) for a set of x values uniformly spaced along the x axis and causing the **Turtle** object to move and connect those points with a blue line. The **Turtle** object was made invisible.

As a practical matter, computing the coordinate values is relatively simple. The more complex problem is to get everything scaled properly to produce a visually pleasing graph in the space provided by the **World** object.

3.3.6.5 Discussion and sample code

I will explain eight different programs in this lesson. Complete listings of those programs are provided in Listing 15 (p. 586) through Listing 22 (p. 599) in the section titled Complete program listings (p. 586) .

As is my custom, I will break the programs down and explain them in fragments. However, I will explain only those portions of the programs that are new to this lesson. I will let the comments in the listings speak to those portions of the code that you should already understand.

Much of the code repeats from one program to the next. I will explain new code the first time that it appears in a program and won't explain that code in the explanation of programs that follow.

3.3.6.5.1 A straight line

In this section, I will present and explain a program named **Line01** that can be used to draw a straight line using the standard formula for a straight line given below:

$$y = \text{slope} * x + \text{yIntercept}$$

A complete listing of the program is provided in Listing 15 (p. 586) near the end of the lesson.

3.3.6.5.1.1 Program output for Line01

Before getting into the code, Figure 3 (p. 566) shows the program output.

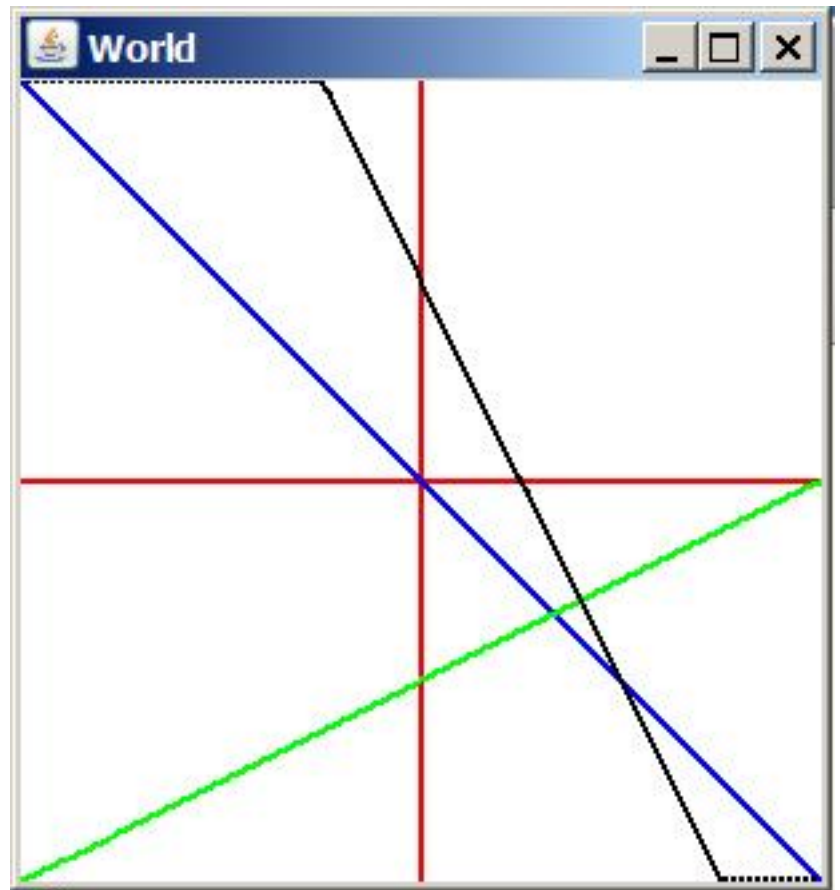

Figure 3. Program output for Line01.

As you can see, in addition to the red axes, this program graphs three different lines in different colors with different slopes and different y-intercept values. I will touch on the slopes and the y-intercept values as I explain the code.

3.3.6.5.1.2 May need multiple points

At this point, I will explain a practical issue before it becomes a concern to you. As we all know, only two points are required to define a line. However the program that I will explain uses multiple points to define and draw a line. This requirement results from the behavior of a **Turtle** object when moving from one point to another point.

A **Turtle** object has the ability to connect two points with a straight line if, and only if, both points are inside the **World** object. If a point is outside the world and a turtle attempts to move to it, the turtle will behave like a dog inside a fenced yard running along the fence and barking at someone who is walking along the sidewalk on the other side of the fence. The turtle will move along the inside boundary of the world. This is indicated by the black horizontal dotted line segments in the upper left and lower right of Figure 3 (p. 566) . In this case, the turtle was trying to reach a point somewhere on the extension of the black line outside the world.

In comparison, Figure 4 (p. 567) shows the same lines as Figure 3 (p. 566) . The horizontal and vertical scaling were adjusted in Figure 4 (p. 567) to ensure that the end points of all three lines are inside the boundaries of the world. These lines could be drawn by a **Turtle** object using only the end points of the lines and only two points would be needed for each line.

Figure 4. Line01 output with different scaling.

In general, a turtle is incapable of reliably drawing a straight line between two points if either or both the points are outside the boundaries of the world even though a line between those points would pass through the world. There are a variety of ways to deal with this issue. The code that I will present below is only one of those ways.

3.3.6.5.1.3 The driver class named Line01

The driver class named **Line01** is shown in Listing 15 (p. 586) . There is nothing new in that code so a detailed explanation should not be required.

The code in the driver class instantiates an object of the class named **Line01Runner** and calls an instance method named **run** belonging to that object. The **run** method is where the action is in the program.

3.3.6.5.1.4 Beginning of the class named Line01Runner

Listing 1 (p. 568) shows the beginning of the class named **Line01Runner** and the beginning of the method named **run** .

Listing 1 . Beginning of the class named Line01Runner.

```
class Line01Runner{
    //Instantiate the World and Turtle objects.
    private World world = new World(300,300);
    private Turtle turtle = new Turtle(0,0,world);
    //-----//

    public void run(){
        //Make the turtle invisible
        turtle.hide();

        //Prepare the pen
        turtle.setPenColor(Color.RED);
        turtle.setPenWidth(2);

        //Draw the axes in RED
        turtle.penUp();
        turtle.moveTo(world.getWidth()/2,0);
        turtle.penDown();
        turtle.moveTo(world.getWidth()/2,world.getHeight());
        turtle.penUp();
        turtle.moveTo(world.getWidth(),world.getHeight()/2);
        turtle.penDown();
        turtle.moveTo(0,world.getHeight()/2);
        turtle.penUp();
        turtle.moveTo(0,0);
    }
}
```

This code fragment is included here strictly for context. There is nothing in Listing 1 (p. 568) that you haven't seen in an earlier lesson.

3.3.6.5.1.5 The method named function for Line01

At this point, I am going to put the **run** method on hold and explain a method named **function** . This method is the heart of the program because it evaluates the standard equation of a straight line given by

$$y = \text{slope} * x + y\text{Intercept}$$

I will return to a discussion of the **run** method later.

The method named **function** is shown in its entirety in Listing 2 (p. 568) . This method evaluates and returns the y-value for each incoming x-value to define a line described by the equation given above.

Listing 2 . The method named function for Line01.

```

double function(double xVar,double slope,double yIntercept){
    double yVar = (yIntercept) + (slope*xVar);
    return yVar;
} //end function

```

As you can see, this method is very simple. I decided to break it out as a separate method to clearly distinguish it from the other code in the `run` method. This will be the case in all of the programs that I explain in this lesson.

3.3.6.5.1.6 Scaling

As I mentioned earlier, the more complex problem is to get everything scaled properly to produce a visually pleasing graph in the space provided by the `World` object as shown in Figure 3 (p. 566) .

Another issue that increases the complexity is the need sometimes to translate the origin from the default upper-left corner of the `World` object to a point at the center of the world.

And if that isn't enough, the problem is further complicated by the need to use mixed-mode arithmetic involving both `int` and `double` data types. Coordinate values in the world must be specified as type `int` . However, if an attempt is made to do all of the arithmetic using integer arithmetic, the results will often be incorrect with no warning. For example, with integer arithmetic, 1 divided by 3 is equal to 0 instead of 0.3333. That fact alone can result in major errors.

The computations in this and the other programs in this lesson will take the following general form (*although some of the steps may be combined in the actual code and may not be easy to isolate*) .

Step 1 . Evaluate the y-value using the equation for a straight line at a set of 101 points along the x-axis ranging from -1.0 through +1.0. Use double-precision arithmetic and return the result as type `double` . This produces y values for the following set of x values:

```
-1.0 -0.98 ... 0.0 ... 0.98 1.0
```

Step 2 . Scale the x and y values by scale factors that produce a pleasing visual display in the available space of the world. For the BLUE line shown in Figure 3 (p. 566) with a slope of 1.0 and a y-intercept value of 0.0 in a 300x300 world, this produces the following x (*col*) and y (*row*) values:

```

-150,-150
-147,-147
...
0,0
...
147,147
150,150

```

Column numbers less than zero are off the left side of the world and row numbers less than 0 are off the top of the world. The origin of the world is at the upper-left corner by default.

Step 3. Adjust the column number by adding one-half the width of the world and adjust the row number by adding one-half the height of the world, This translates the origin to the center of the world. Use these values when telling the turtle to move to a particular location specified by a column number and a row number.

While this approach may seem overly complicated, it has one major advantage. In particular, the results are independent of the dimensions of the world. For example, the results shown in Figure 3 (p. 566) are for a 300x300 world. If I were to change the dimensions of the world to 400x150 near the top of Listing 15 (p. 586) without making any other changes relative to Figure 3 (p. 566) , the output would change to that shown in Figure 5 (p. 570) , which is still correct.

Figure 5. Program output for Line01 for a 400x150 world.

3.3.6.5.1.7 Draw the BLUE line

The code in Listing 3 (p. 570) initializes several variables and then calls a method named **drawLine** to implement the steps listed above (p. 569) to draw the BLUE line shown in Figure 3 (p. 566) .

Listing 3 . Draw the BLUE line.

```
double xScale = 1.0*world.getWidth()/2;
double yScale = 1.0*world.getHeight()/2;

//Draw a line in BLUE.
turtle.setPenColor(Color.BLUE);
double slope = 1.0;
double yIntercept = 0.0;
drawLine(xScale,yScale,slope,yIntercept);
```

3.3.6.5.1.8 The method named drawLine

Once again, I will put the run method on hold while we examine the code that actually draws the line as shown in Listing 4 (p. 570) .

Listing 4 . The method named drawLine.

```
void drawLine(double xScale,double yScale,
              double slope,double yIntercept){
    double yVal = 0;
    int row = 0;
    int col = 0;
    double xVal = -1.0;
```

```

for(int cnt=0; cnt<=100;cnt++,xVal += 0.02){
    //Get a y-value for a given x-value.
    yVal = function(xVal,slope,yIntercept);

    //Scale the x and y values to match the plotting surface
    col = (int)(xVal*xScale);
    row = (int)(yVal*yScale);

    //Move to the first point without drawing a line because the
    // pen is not down. Translate the origin to the center in the
    // process.
    turtle.moveTo(col + world.getWidth()/2,
                  row + world.getHeight()/2);

    //Lower the pen in order to draw a line from each point to the
    // next point.
    turtle.penDown();
} //end for loop
} //end drawLine method

```

If you examine the code in Listing 4 (p. 570) along with values assigned to the variables in Listing 3 (p. 570), you should be able to see the correlation between the code and the steps given earlier (p. 569). In particular, you should be able to see how this code produces the BLUE line shown in Figure 3 (p. 566).

Note that the code in Listing 4 (p. 570) calls the method named **function** (shown in Listing 2 (p. 568)) to get the values that define the line for the given slope and the given y-intercept value.

3.3.6.5.1.9 Repeat the process to draw two more lines

Returning to the **run** method, the code in Listing 5 (p. 571) repeats the process twice to draw the GREEN line and the BLACK line shown in Figure 3 (p. 566) for different slope and y-intercept values.

Listing 5 . Repeat the process to draw two more lines.

```

//Draw another line in GREEN.
turtle.penUp();
turtle.setPenColor(Color.GREEN);
slope = -0.5;
yIntercept = 0.5;
drawLine(xScale,yScale,slope,yIntercept);

//Draw another line in BLACK.
turtle.penUp();
turtle.setPenColor(Color.BLACK);
slope = 2.0;
yIntercept = -0.5;
drawLine(xScale,yScale,slope,yIntercept);

} //end run method

```

Listing 5 (p. 571) also signals the end of the **run** method and the end of the program.

3.3.6.5.2 A parabola

The program named **Parabola01** shown in Listing 16 (p. 588) produces the graphic output shown in Figure 6 (p. 572) .

Figure 6. Graphic output from the program named Parabola01.

3.3.6.5.2.1 The method named function for Parabola01

The method named **function** for the program named **Parabola01** is shown in Listing 6 (p. 572) .

This method evaluates and returns the y-value for each incoming x-value for a parabola with no offsets centered at the origin as defined by the following equation:

$$y = x*x$$

Listing 6 . The method named function for Parabola01.

```
double function(double xVal){
    double yVal = xVal*xVal;
    return yVal;
} //end function
```

A plot of the output of the method named **function** would look like the curve shown in Figure 7 (p. 573) with no offsets if the x and y scaling values were set to one-half the width and height of the world respectively.

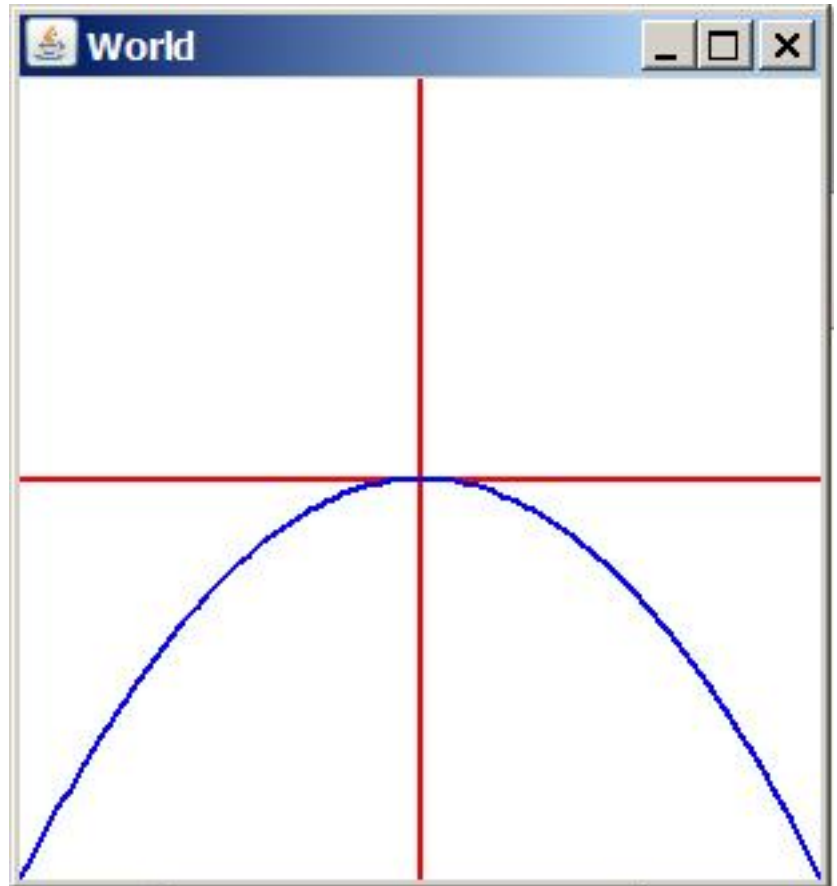

Figure 7. Parabola with zero offsets.

It will be instructive to see how this program uses offsets and scaling values to transform the image shown in Figure 7 (p. 573) into the image shown in Figure 6 (p. 572) .

3.3.6.5.2.2 Drawing parameters for Parabola01

The code fragment shown in Listing 7 (p. 573) shows the drawing parameters that were used to produce the output shown in Figure 6 (p. 572) .

Listing 7 . Drawing parameters for Parabola01.

```
double xOff = 0.25;//offset relative to 1.0
double yOff = -0.25;
double xScale = 0.75*world.getWidth()/2;
double yScale = 1.25*world.getHeight()/2;
```

3.3.6.5.2.3 Drawing parameters with zero offsets

The parameters that were used to produce the output shown in Figure 7 (p. 573) are shown below:

```
double xOff = 0.0;//offset relative to 1.0
double yOff = -0.0;
double xScale = 1.0*world.getWidth()/2;
double yScale = 1.0*world.getHeight()/2;
```

Note in particular that the offsets given by **xOff** and **yOff** are set to zero and the scale factors given by **xScale** and **yScale** are one-half the width and height of the world respectively.

3.3.6.5.2.4 Changing the offset values

Increasing the offsets for **xOff** and **yOff** to 0.25 and -0.25 respectively as shown in Figure 7 (p. 573) and making no other changes produces the output shown in Figure 8 (p. 574)

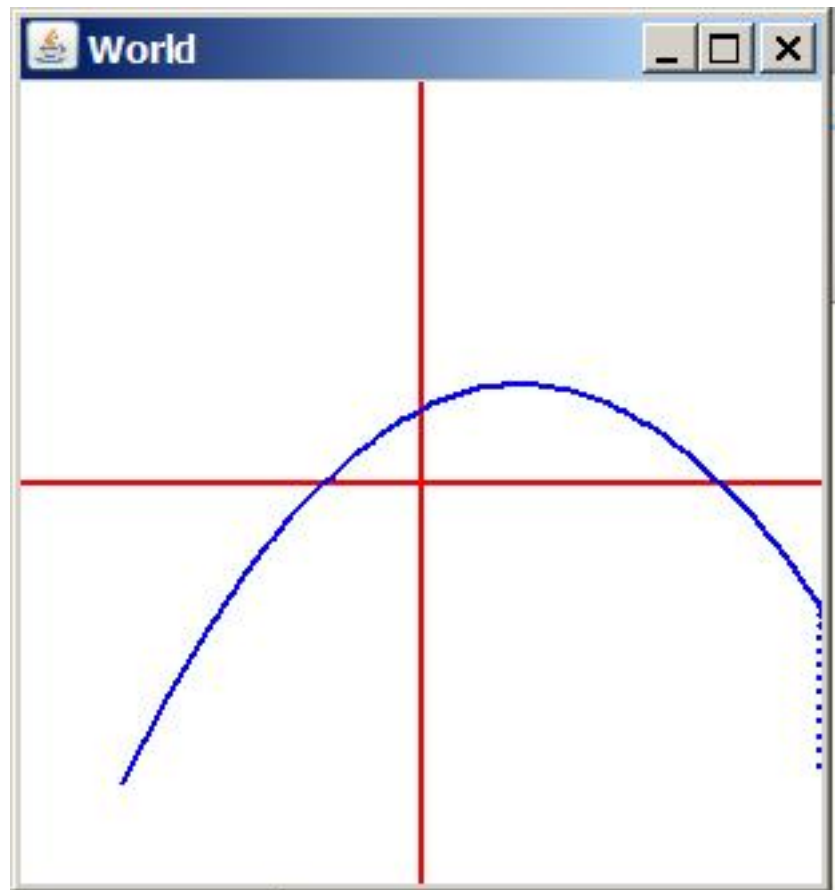

Figure 8. A parabola with offsets.

In comparison with Figure 7 (p. 573) , changing the value of **xOff** to 0.25 caused the peak to move to the right (*positive direction*) one-fourth of the way from the center origin to the right edge of the world. (*That change also caused a portion of the curve to fall outside the right boundary of the world.*)

Similarly, changing the value of **yOff** to -0.25 caused the peak to move up (*negative direction*) one-fourth of the way from the center origin to the top edge of the world.

3.3.6.5.2.5 Changing the scale factors

Following that, changing the values of `xScale` and `yScale` to the values shown in Listing 7 (p. 573) produces the graphic output shown in Figure 6 (p. 572) . The change in `xScale` decreased the total width of the curve and prevented it from exceeding the rightmost boundary of the world. The change in `yScale` increased the overall height of the curve causing it to almost touch the lower boundary of the world.

3.3.6.5.2.6 Draw the parabolic function in BLUE

The code in Listing 8 (p. 575) draws the blue parabolic function shown in Figure 6 (p. 572) .

Listing 8 . Draw the parabolic function in BLUE.

```
double yVal = 0;
int row = 0;
int col = 0;
double xVal = -1;
turtle.setPenColor(Color.BLUE);

for(int cnt=0; cnt<=100;cnt++,xVal += 0.02){
    //Get a y-value for the given x-value.
    yVal = function(xVal);

    //Apply the offsets and scale the results
    col = (int)((xOff+xVal)*xScale);
    row = (int)((yOff+yVal)*yScale);

    //Move to the first point without drawing a line because the
    // pen is not down. Translate the origin to the center in the
    // process.
    turtle.moveTo(col + world.getWidth()/2,
                  row + world.getHeight()/2);

    //Lower the pen in order to draw a line from each point to the
    // next point.
    turtle.penDown();
} //end for loop

} //end run method
```

There is nothing new in Listing 8 (p. 575) . You should be able to correlate the code in Listing 8 (p. 575) and the drawing parameters in Listing 7 (p. 573) with the steps (p. 569) presented earlier to understand how the program named **Parabola01** produces the output image shown in Figure 6 (p. 572) .

3.3.6.5.3 A cubic

The program named **Cubic01** shown in Listing 17 (p. 590) produces the graphic output shown in Figure 9 (p. 575)

Figure 9. Graphic output from the program named Cubic01.

About the only thing that is different between the program named **Parabola01** and the program named **Cubic01** is the method named **function**. In the program named **Parabola01**, the method computes and returns the square of the incoming x-value. In the program named **Cubic01**, the method computes and returns the cube of the incoming x-value. Just about everything that was said about **Parabola01** also applies to **Cubic01**.

3.3.6.5.4 A circle

There are several ways to graph all of the functions discussed in this lesson. The previous sections have illustrated only one way – using a turtle to graph the function. I will illustrate the following two ways to graph a circle in this section and will compare some of the advantages and disadvantages **of each approach**:

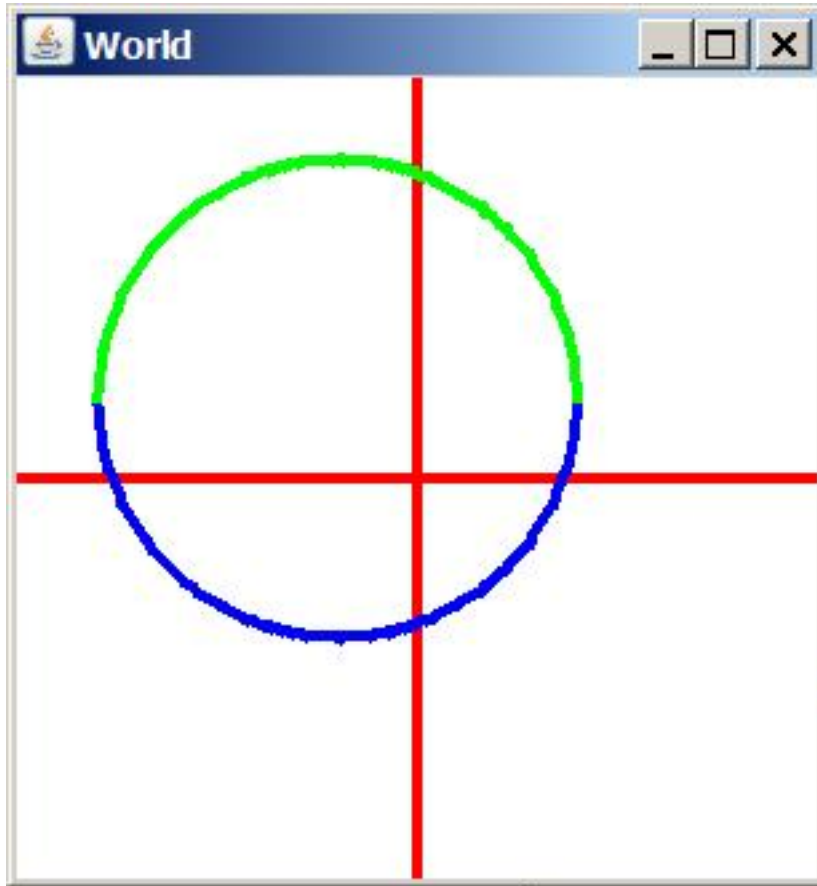

- Using a turtle to graph the function
- Accessing and setting pixel colors

3.3.6.5.4.1 First approach

The first approach that I will present and explain uses a turtle to graph a circle. This program is very similar to the program named **Parabola01**, but there are a few differences. I will explain those differences.

The program named **Circle01** shown in Listing 18 (p. 591) produces the graphic output shown in Figure 10 (p. 577).

Figure 10. Graphic output from the program named Circle01.

The first difference that is worthy of note is shown by the lines of code involving the variable named **rVal** in Listing 9 (p. 577) .

Listing 9 . The variable named rVal.

```
double rVal = 0.6;//radius relative to 1.0
double yVal = 0;
int row = 0;
int col = 0;
double xVal = -rVal;
double xInc = 2*rVal/100;
turtle.setPenColor(Color.BLUE);
```

The variable named **rVal** is used to specify the radius of the circle relative to a value of 1.0 as declared and initialized in Listing 9 (p. 577) .

In the previous sections, we have evaluated our equation for a set of 101 x values ranging from -1.0 to +1.0. For the case of the circle, we will evaluate the equation for a set of 101 x values ranging from **-rVal** to **+rVal** . (*There is no point in evaluating the equation outside of the circle.*)

The code in Listing 9 (p. 577) declares and initializes the variable named **rVal** . Further down, the code sets the initial value for **xVal** to **-rVal** . Below that, the code sets the x-increment (**xInc**) to the diameter of the circle divided by 100. This will cause the equation for the circle to be evaluated at 101 points from left to right across the circle shown in Figure 10 (p. 577) .

3.3.6.5.4.1.1 The method named function for Circle01

The method named **function** is shown in Listing 10 (p. 578) .

This method evaluates and returns the y-value for each incoming x-value for a circle with no offset, centered at the origin. The method evaluates the standard equation for a circle given by

$$\text{radius} \times \text{radius} = x \times x + y \times y$$

Note that unlike the **function** method for **Parabola01** and **Cubic01** , this method requires two incoming parameters: the radius and the current x-value.

The value returned from the **Math.sqrt** method can be considered to be either positive or negative. Only the positive value is returned by this method. When the returned value is considered to be positive and the results are plotted, one-half of a circle is displayed as shown by the BLUE line in Figure 10 (p. 577) . Similarly, when the returned value is considered to be negative and the results are plotted, the other half of the circle is displayed as shown by the GREEN line in Figure 10 (p. 577) .

Listing 10 . The method named function for Circle01.

```
double function(double rVal,double xVal){
    double yVal = Math.sqrt(rVal*rVal - xVal*xVal + 0.000000001);
    return yVal;
} //end function
```

If the expression passed to the **sqrt** method is negative, the value returned by that method will not be valid. Because the computations in this program are performed as type **double** , and because all floating point computations are only estimates of the truth, the computed difference between the radius squared and the x-value squared can actually be an extremely small negative value when it should be zero. A small positive fudge factor was added to prevent that value from going negative due to small floating point computational errors. *(This sort of thing is often required when doing a lot of floating point computations. There are various ways to do it and there may be better ways than the one used here.)*

3.3.6.5.4.1.2 Draw half the circle in BLUE

The code in Listing 11 (p. 578) draws the BLUE half of the circle shown in Figure 10 (p. 577) .

Listing 11 . Draw half the circle in BLUE.

```
for(int cnt=0; cnt<=100;cnt++,xVal += xInc){
    //Get a y-value for the given x-value.
    yVal = function(rVal,xVal);

    //Apply the offsets and scale the results
    col = (int)((xOff+xVal)*xScale);
    row = (int)((yOff+yVal)*yScale);

    //Move to the first point without drawing a line because the
    // pen is not down. Translate the origin to the center in the
    // process.
    turtle.moveTo(col + world.getWidth()/2,
                  row + world.getHeight()/2);
    //Lower the pen in order to draw a line from each point to the
    // next point.
```

```

    turtle.penDown();
} //end for loop

```

Having initialized `xVal` and `xInc` on the basis of the radius in Listing 9 (p. 577) , the code in Listing 11 (p. 578) is essentially the same as the code in the earlier programs in this lesson.

3.3.6.5.4.1.3 Draw the other half of the circle in GREEN

The code that draws the GREEN half of the circle is shown in Listing 18 (p. 591) . It is essentially the same as the code in Listing 10 (p. 578) except that the sign on `yVal` is flipped from positive to negative as discussed above (p. 578) .

3.3.6.5.4.1.4 Different line width

One other difference that I haven't mentioned yet is trivial but interesting. You may have noticed that the line width in Figure 10 (p. 577) is about twice that in Figure 9 (p. 575) . I purposely did that to illustrate that one of the useful features of graphing functions with a turtle is that you can control the width of the line. The importance of that capability will become apparent in the next section.

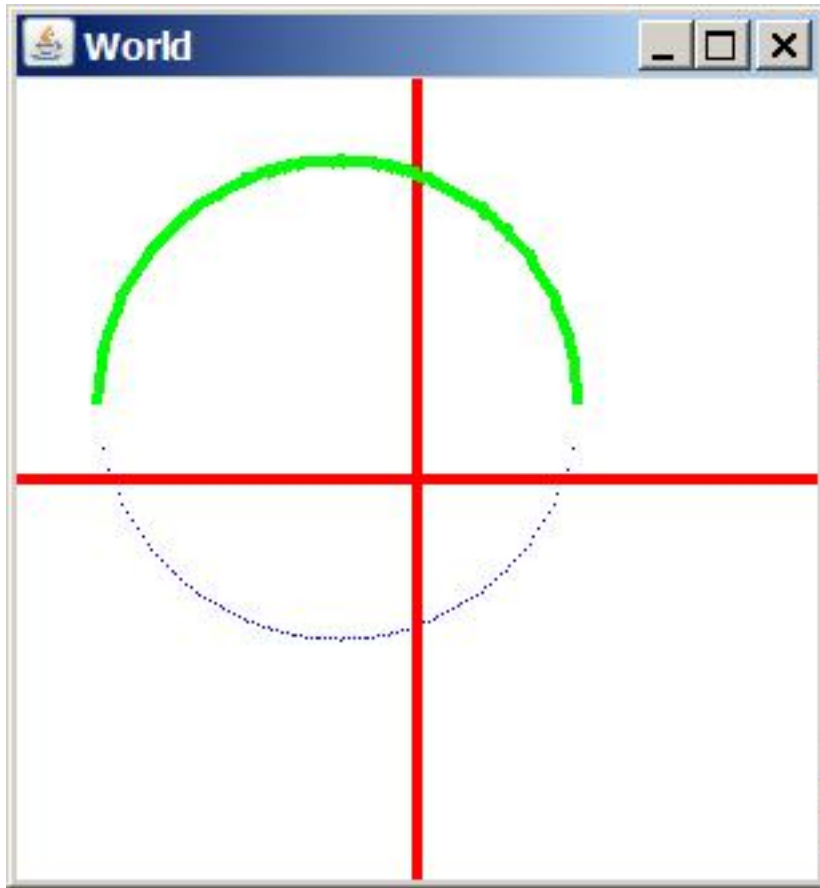

That concludes the interesting differences between this program and the previous programs.

3.3.6.5.4.2 Second approach

The program named `Circle02` shown in Listing 19 (p. 594) produces the graphic output shown in Figure 11 (p. 579) .

The bottom half of the circle in Figure 11 (p. 579) was drawn using the second approach (p. 576) : accessing and setting pixel colors. As you can see, the quality is rather poor in comparison with the upper half that was drawn by using a turtle to graph the function.

Figure 11. Graphic output from the program named `Circle02`.

For example, if the curve is anything other than a straight line, a considerable programming effort is usually required to cause the line width to be greater than one pixel using this approach. Also, when you use this approach, if you want to produce a solid line, you must make certain that you don't skip any pixels when setting the pixel colors to represent the line. You can avoid both of these issues by using a turtle to draw the lines in your graph.

There are situations, however, where this approach will produce satisfactory results with less programming effort than would be the case using a turtle to draw the lines, so you should not discount this method entirely.

I will explain the programming differences involved in using this approach to draw the BLUE half circle as compared to the approach used in the program named **Circle01**.

The code in Listing 12 (p. 580) is new compared to the code for the program named **Circle01**.

Listing 12 . Picture and Pixel references.

```
private Picture pic = world.getPicture();
private Pixel pixel = null;
```

This code appears near the top of Listing 19 (p. 594). The first statement gets a reference to the white **Picture** object that forms a background image in the **World** object.

The second statement in Listing 12 (p. 580) declares a variable of type **Pixel** that will be used as a working variable later.

The code in Listing 13 (p. 581) replaces the code that causes the turtle to move and draw a line segment in Listing 11 (p. 578). This code translates the origin to the center and sets the color of a pixel on the circumference of the half circle to the color BLUE.

Listing 13 . Translate the origin and set the pixel color.

```
pixel = pic.getPixel(col + world.getWidth()/2,
                    row + world.getHeight()/2);
pixel.setColor(Color.BLUE);
```

Note however that pixel colors are only set for the values of `col` that are computed in Listing 11 (p. 578) . If there are gaps in the column numbers, there will be gaps in the line as shown in Figure 11 (p. 579) . The turtle approach, on the other hand, draws the line across such gaps. If the gaps are large, the curve may be jagged with the turtle approach, but there won't be empty gaps as in Figure 11 (p. 579) .

Figure 11 (p. 579) also illustrates the difference between having easy control over the line width and not having easy control over the line width. As mentioned above, unless the curve is a straight line, it can be very difficult to control the line width with this approach.

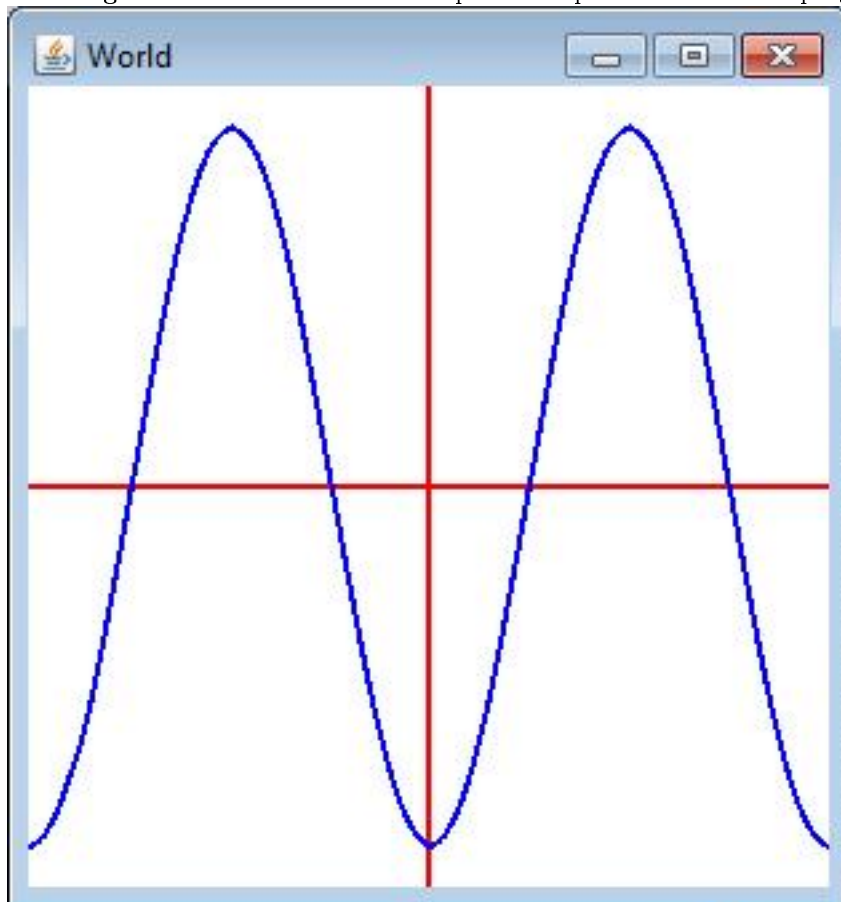

Once again, however, there are situations where the approach of setting pixel colors will provide satisfactory results with minimum effort, so you should always keep this approach as an option.

That is probably all that needs to be said about the program named `Circle02` .

3.3.6.5.5 A cosine

The program named `Cosine01` shown in Listing 20 (p. 596) produces the graphic output shown in Figure 12 (p. 581) .

Figure 12. Graphic output from the program named `Cosine01`.

The only significant difference between this program and the program named **Parabola01** is the method named **function** shown in Listing 14 (p. 582) .

Listing 14 . The method named function for Cosine01.

```
double function(double xVal){
    double yVal = Math.cos(2*Math.PI*xVal);
    return yVal;
} //end function
```

This method evaluates and returns the y-value for each incoming x-value for a cosine function with no offset centered at the origin.

$$y = \cos(2\pi x)$$

Figure 12 (p. 581) shows two cycles of the cosine curve, which is periodic. When viewing Figure 12 (p. 581) , keep in mind that positive values go down the page. Thus the positive peak of the cosine function at the origin points down.

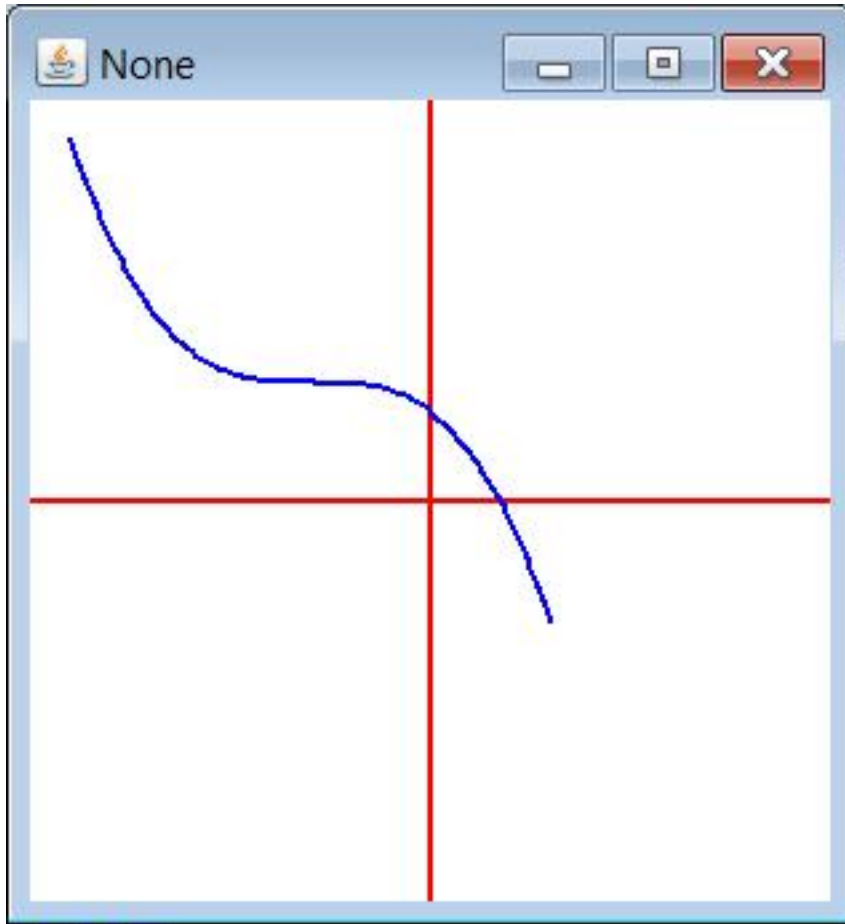

As in the previous section, that is probably all that needs to be said about the program named **Cosine01** .

3.3.6.5.6 Using a Turtle object without a World object

A **Turtle** object can be used to draw on a **Picture** object as shown by the program named **Cubic02** in Listing 21 (p. 598) . If you examine this code, you will see that there is no reference to the **World** class in this program.

The output from this program is shown in Figure 13 (p. 582) .

Figure 13. Graphic output from the program named Cubic02.

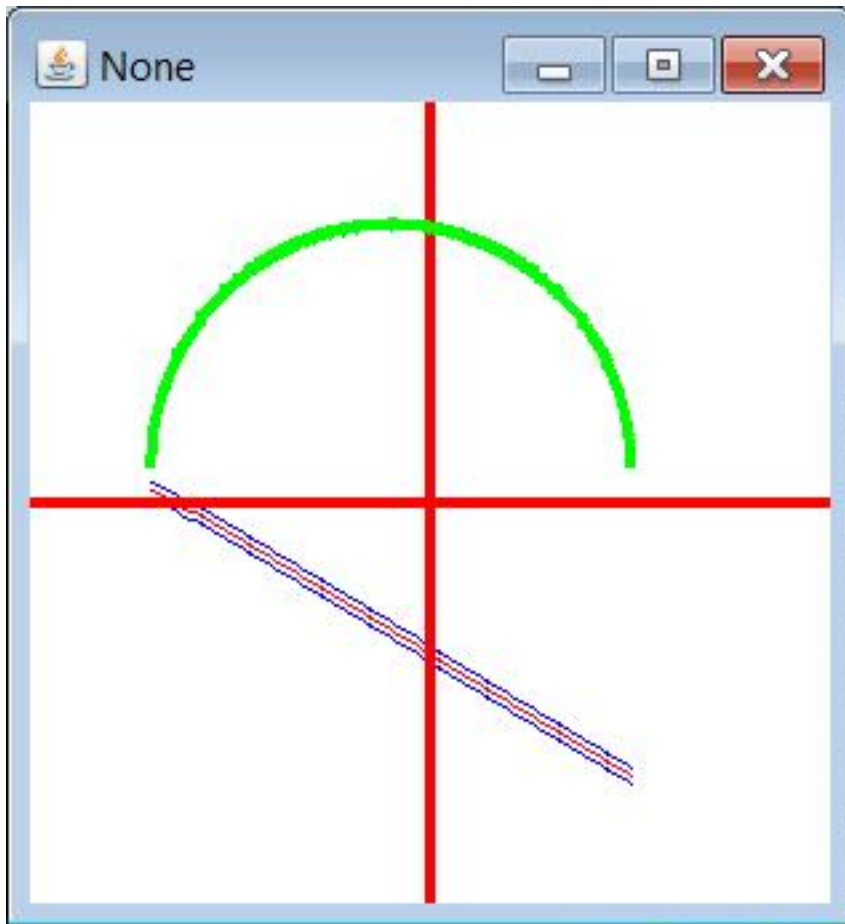

If you compare Figure 13 (p. 582) with Figure 9 (p. 575) , you will see that they display the same image with the exception of the word that appears in the blue banner at the top of the image.

3.3.6.5.7 Drawing straight lines without a Turtle object

Although a **Turtle** object provides a very convenient way to draw a straight line with a specified color and width, that is not the only way to draw a straight line. The program named **Line02** shown in Listing 22 (p. 599) draws three parallel straight lines without using a **Turtle** object. (*Listing 22 (p. 599) also shows how to draw a half circle using a **Turtle** object without a **World** object.*)

The code in Listing 22 (p. 599) produces the graphic output shown in Figure 14 (p. 583) .

Figure 14. Graphic output from the program named Line02.

If you compare Figure 14 (p. 583) with Figure 11 (p. 579) , you will see that the top halves of the two images are the same except for the word that appears in the banner at the top. However, instead of drawing a half circle without using a **Turtle** object as in the bottom half of Figure 11 (p. 579) , the program named **Line02** draws three parallel lines of different colors without using a **Turtle** object. (*The lines are separated by two pixels in the vertical dimension.*)

3.3.6.5.7.1 What is the "pen width" for the straight lines?

On first glance, one might conclude that by causing the three straight lines in Figure 14 (p. 583) to be side-by-side with no white space in between, one could use this approach to create a line with a "pen width" of three pixels. That is not necessarily the case, however, unless the three lines are either horizontal or vertical.

Consider what would happen if each individual line in Figure 14 (p. 583) were to be rotated around its left-most pixel until it becomes vertical. In that case, all three lines would occupy the same vertical column of pixels and the resulting "line" would be only one pixel wide. Thus, with this approach, the actual width of the combined lines depends on the angle that the line makes with the horizontal.

That is not the case for a line that is drawn using a **Turtle** object. Note that the GREEN half circle drawn by the turtle in the upper half of Figure 14 (p. 583) is the same width no matter what the angle of an individual line segment is relative to the horizontal.

This approach to drawing straight lines can be used to draw lines with a visually pleasing width but you need to be careful about using this approach to create a line with a specified width. Normally the specified width would be measured along an axis that is perpendicular to the line.

For example, consider the three individual lines and the spaces between individual lines taken together in Figure 14 (p. 583) to represent a LINE. If each of the three individual lines were to be rotated around its left-most pixel so that they are horizontal, the width of the LINE, measured perpendicular to the LINE would be seven pixels (three lines and four spaces). As explained above, if each of the three individual lines were to be rotated so as to become vertical, the width of the LINE would be one pixel.

If the specifications were to state that the width of the LINE in Figure 14 (p. 583) must be seven pixels, and the LINE is not horizontal, some trigonometric computations might be required in the algorithm to achieve that goal.

For example, if the three individual lines in Figure 14 (p. 583) were to be rotated around their left-most pixel so as to be at forty-five degrees relative to the horizontal, the actual width of the LINE would be $(7 * 0.707)$ or 4.949 pixels. Since it is not possible to address the space between pixels, the actual width would probably be rounded up to five pixels or truncated down to four pixels (*depending on the method used to convert from double to int*) . (Recall that the cosine of 45 degrees is 0.707.)

This is illustrated in Figure 15 (p. 585) .

Figure 15. Zoomed comparison of lines.

Figure 15 (p. 585) shows the three lines rotated to an angle of 45 degrees and connected to a line segment drawn by a Turtle object with a pen width of seven pixels. (*Note that the image was zoomed to make it possible to see the individual pixels.*) As you can see, the width of the line segment drawn by the turtle is greater than the combined widths of the three individual lines by what appears to be two pixels. This effect becomes more pronounced as the orientation of the three lines approaches the vertical.

Thus, if the width of a line is part of a specification, and the specified width is anything other than one pixel, you might find it easier to use a **Turtle** object to draw the line.

3.3.6.6 Run the programs

I encourage you to copy the code from Listing 15 (p. 586) through Listing 22 (p. 599) . Execute the code and confirm that you get the same results as those shown in in this lesson. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

3.3.6.7 Complete program listings

Complete listings of the programs discussed in this lesson are provided in Listing 15 (p. 586) through Listing 20 (p. 596) below.

3.3.7.3 Preview

The program that I will explain in this module is designed to be used as a test of the student's understanding of programming using Java and Ericson's media library.

The student is provided an image file named **Prob02.jpg** along with a pair of **PictureExplorer** windows containing the raw image and a modified version of the image. (See *Figure 1 (p. 610)* and *Figure 2 (p. 616)* .)

Deduce the algorithm

The first part of the test is to determine if the student can examine the raw image shown in the **PictureExplorer** window in *Figure 1 (p. 610)* and deduce the algorithm required to produce the output shown in the **PictureExplorer** window in *Figure 2 (p. 616)* .

Implement the algorithm

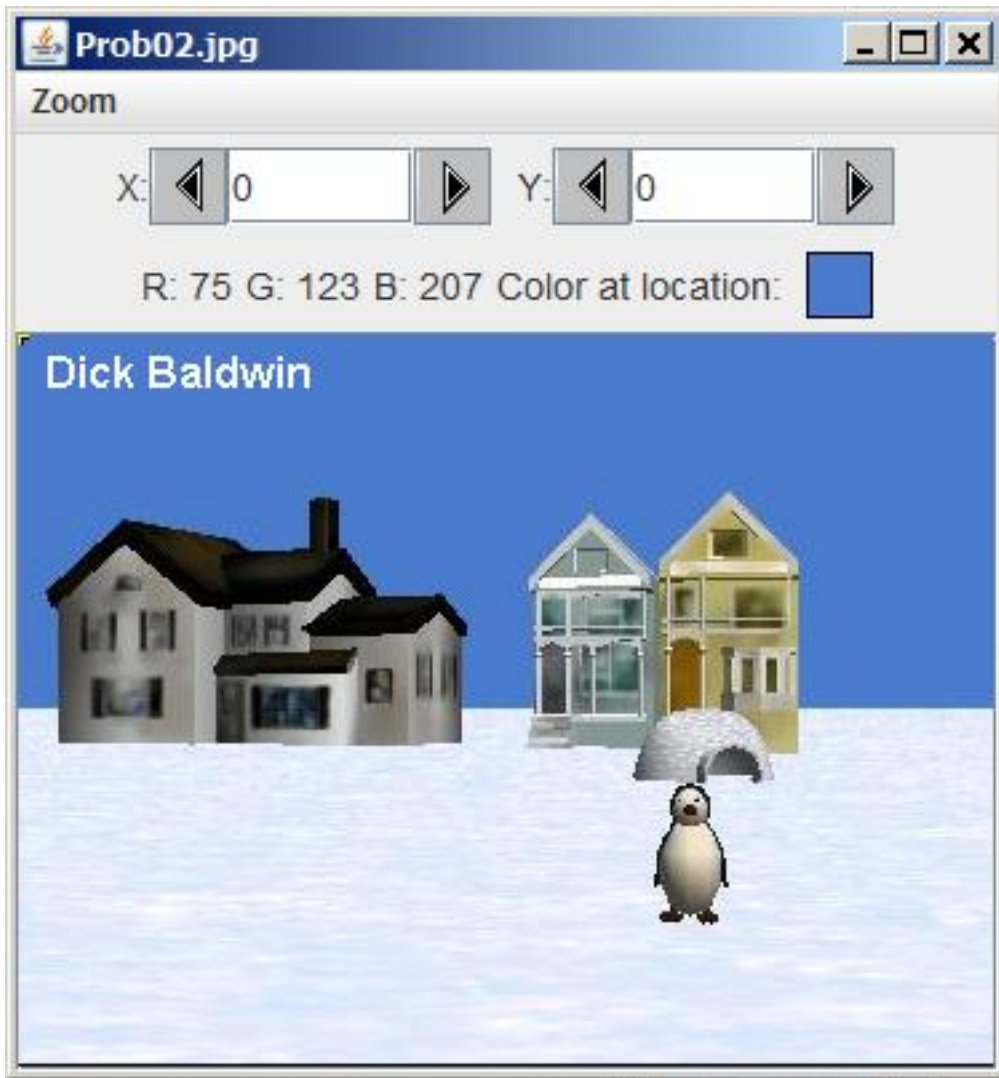

The second part of the test is to determine if the student can implement the algorithm once it is established and also satisfy some requirements for text output on the command line screen. Among other things, this requires that the student be able to:

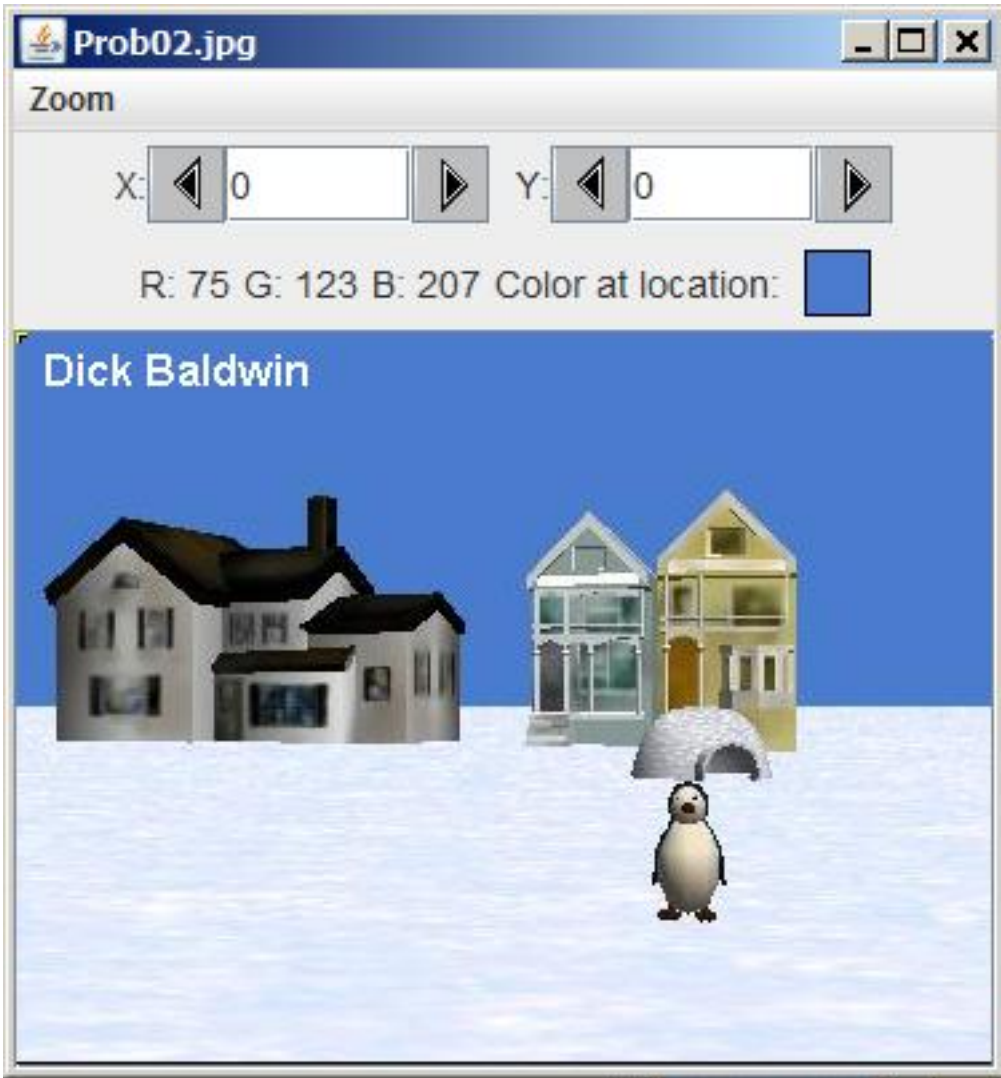

- Create a **Picture** object from an image file.
- Write an accessor method to return a reference to the **Picture** object.
- Modify the pixels in the picture according to the algorithm.
- Display the raw picture and the modified picture in **PictureExplorer** objects by calling the **explore** method on the **Picture** object before and after it is modified.

Program output

The raw image is displayed in the **PictureExplorer** window shown in *Figure 1 (p. 610)* .

Figure 1. The raw image .

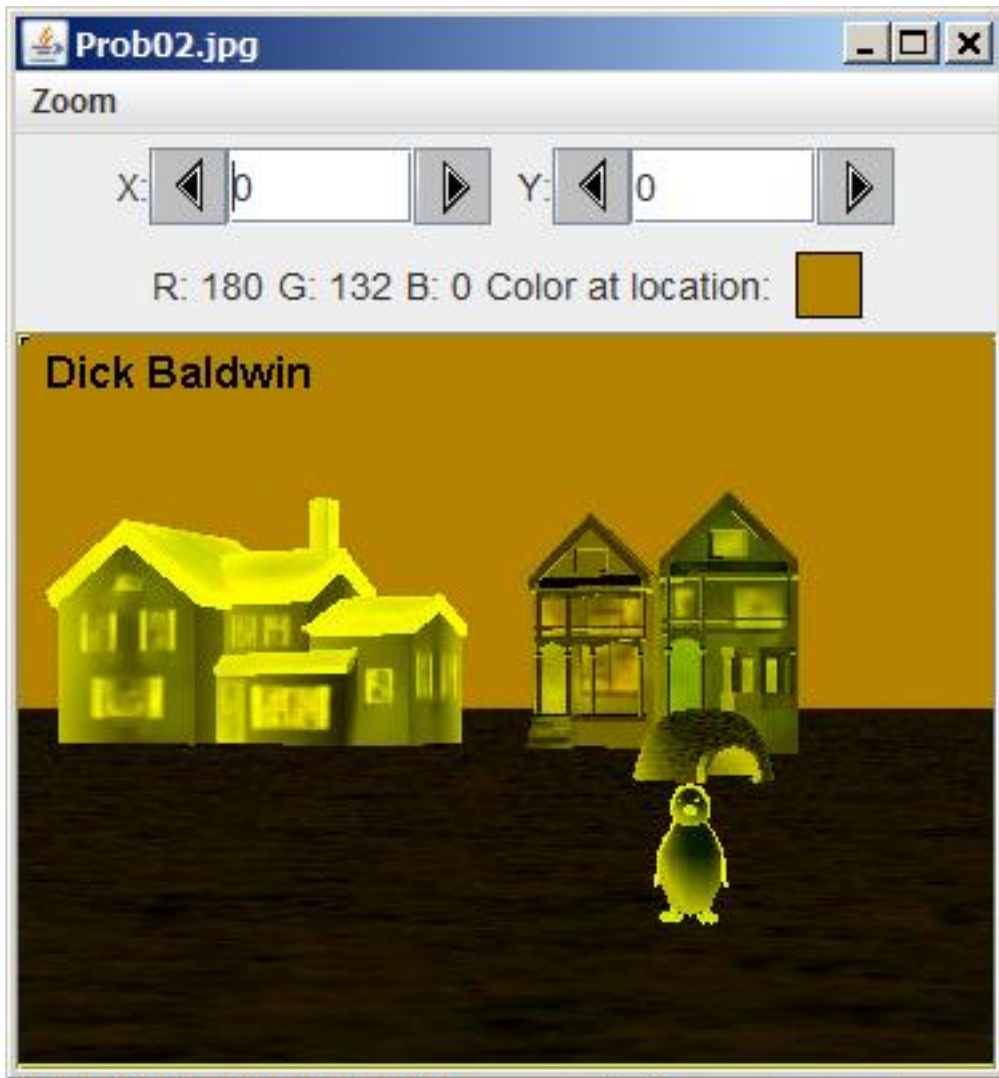

Table 3.204

The modified image is shown in the **PictureExplorer** window in Figure 2 (p. 616) .

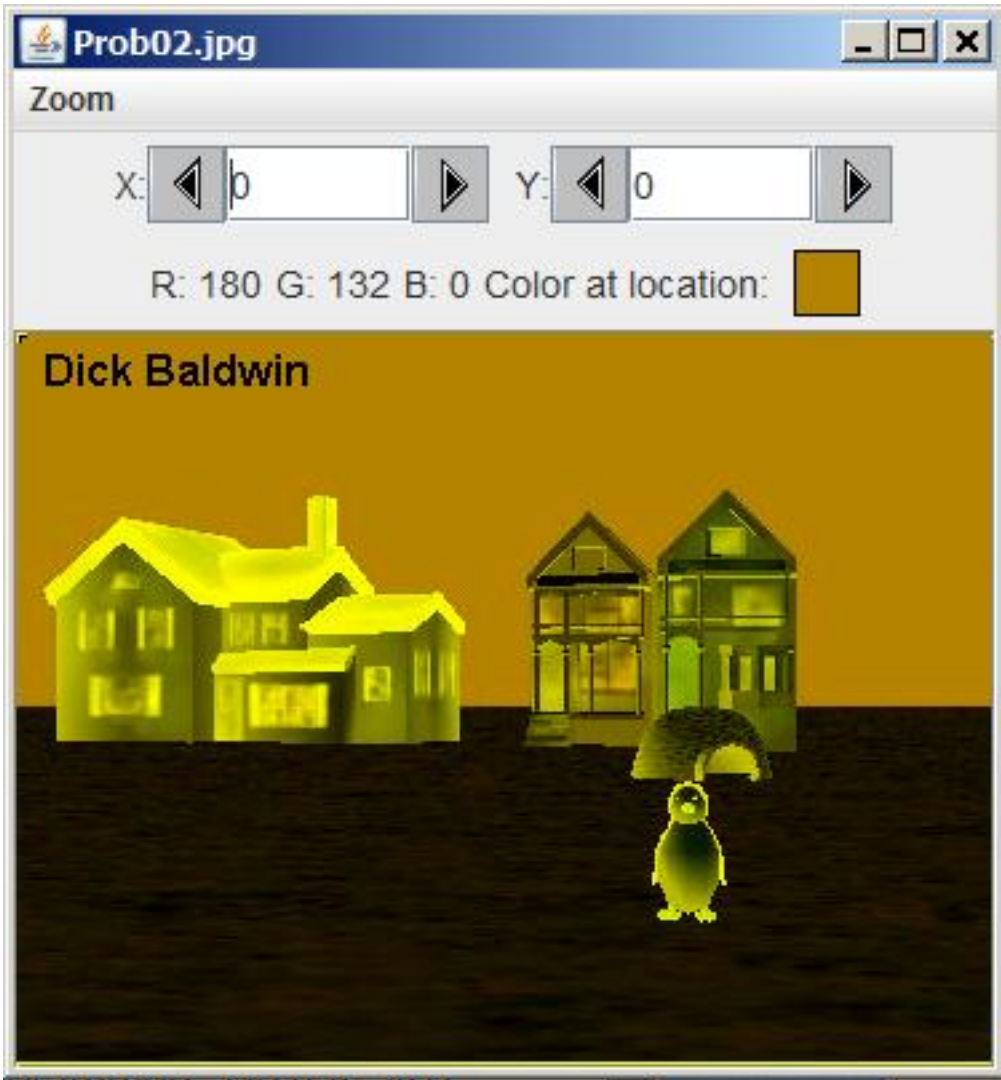

Figure 2. The modified image .

Table 3.205

The required output on the command-line screen is shown by the last two lines of text in Figure 3 (p. 616) . The other text in Figure 3 (p. 616) was produced by the system during the compilation and execution process.

Figure 3 . Output text on the command line screen.

Table 3.206**The algorithm**

The algorithm required to transform the image from Figure 1 (p. 610) to Figure 2 (p. 616) is:

- Set the blue color value for every pixel to zero.
- Invert the red and green color values for every pixel.

A color value is inverted by subtracting the value from 255 and using the difference as the new color value.

Obvious that the blue color value is reduced to zero

It should be obvious to the student when comparing the two images in the **PictureExplorer** objects that the blue pixel value has been set to zero for every pixel in the modified image.

Color inversion is not quite so obvious

Deducing that the red and green colors in the output pixels are the inverse of the red and green colors in the input image isn't quite as straightforward. However, using algebra to compare several corresponding pixels in the two images should make it obvious fairly quickly to the curious student.

The implementation of the algorithm will be explained below.

3.3.7.4 Discussion and sample code**Will explain in fragments**

I will explain this program in fragments. A complete listing is provided in Listing 6 (p. 624) near the end of the module.

I will begin with the driver class named **Prob02**, which is shown in its entirety in Listing 1 (p. 617).

Listing 1 . The driver class.

```

public class Prob02{//the driver class
public static void main(String[] args){
    Prob02Runner obj = new Prob02Runner();

    obj.run();

    System.out.println(obj.getPicture());
} //end main
} //end class Prob02

```

Table 3.207

You should already be familiar with everything in Listing 1 (p. 617) . The most important aspect of Listing 1 (p. 617) for purposes of this discussion is the call to the **run** method belonging to the object instantiated from the **Prob02Runner** class. I will explain the **run** method shortly.

Beginning of the class named Prob02Runner

The class definition for the class named **Prob02Runner** begins in Listing 2 (p. 618) .

Listing 2 . Beginning of the class named Prob02Runner.

```
class Prob02Runner{
private Picture pic = new Picture("Prob02.jpg");

public Prob02Runner(){//constructor
    System.out.println("Dick Baldwin");
} //end constructor
//-----//

//Accessor method
public Picture getPicture(){return pic;}
```

Table 3.208

Again, you should be familiar with everything in Listing 2 (p. 618) . I will simply highlight the instantiation of a new **Picture** object using an image file as input and the saving of a reference to that object in the private instance variable named **pic** .

The beginning of the run method

The **run** method begins in Listing 3 (p. 618) . This is where the action is, so to speak.

Listing 3 . The beginning of the run method.

```
public void run(){

pic.sendMessage("Dick Baldwin",10,20);

pic.explore();
```

Table 3.209

You are already familiar with the call to the **sendMessage** method to add my name as text to the image encapsulated in the **Picture** object. (See Figure 1 (p. 610) .)

The explore method

The call to the **explore** method is new to this module.

The **explore** method is defined in the **SimplePicture** class, which is the superclass of the **Picture** class. The method is inherited into the **Picture** class.

Javadocs description of the explore method

The javadocs description of this method is shown in Figure 4 (p. 619) .

Figure 4 . javadocs description of the explore method.

Method to open a picture explorer on a copy of this simple picture.

Table 3.210**Result of calling the explore method**

The result of calling the `explore` method in Listing 3 (p. 618) is to create and display the **PictureExplorer** object shown in Figure 1 (p. 610) .

Very important capability

The availability of the `explore` method and the **PictureExplorer** class is very important in at least two respects:

- The `explore` method makes it easy to display copies of an image at various stages during the processing of the image. Once the **PictureExplorer** object is created and displayed, it won't be effected by subsequent changes to the image.
- The availability of a **PictureExplorer** object makes it easy to manually analyze the colors of the individual pixels in an image encapsulated in that object.

Implementing the algorithm

The code in Listing 4 (p. 619) implements the algorithm required to modify the original image to make it look like the image shown in Figure 2 (p. 616) .

Listing 4 . Implementing the algorithm.

```
Pixel[] pixelArray = pic.getPixels();

for(Pixel pixel:pixelArray ){
    pixel.setRed(255 - pixel.getRed());
    pixel.setGreen(255 - pixel.getGreen());
    pixel.setBlue(0);
} //end for loop
```

Table 3.211

In particular, the code in Listing 4 (p. 619) sets the blue color components to 0 and inverts the red and green color components for every pixel in the picture.

One of several approaches

There are several ways to do this, and this is only one of those ways. This approach makes use of a method named `getPixels` that is defined in the **SimplePicture** class and inherited into the **Picture** class.

Very useful when...

This approach is particularly useful when you want to perform the same action on every pixel in an image. The advantage is that you don't have to worry about horizontal and vertical coordinates with this approach. Access to all of the pixels is provided in a one-dimensional array.

javadocs description of the getPixels method

The javadocs description of this method is shown in Figure 5 (p. 620) .

Figure 5 . javadocs description of the getPixels method.

Method to get a one-dimensional array of
Pixels for this simple picture.

Returns: a one-dimensional array of Pixel
objects starting with y=0 to y=height-1
and x=0 to x=width-1.

Table 3.212**What is a Pixel object?**

An object of Ericson's **Pixel** class encapsulates an individual pixel from an image. Figure 6 (p. 620) shows the javadocs description of the **Pixel** class.

Figure 6 . javadocs description of the Pixel class.

Class that references a pixel in a picture.

A pixel has an x and y location in a picture.

A pixel knows how to get and set the red, green,
blue, and alpha values in the picture.

A pixel also knows how to get and set the color
using a Color object.

Table 3.213**Many methods available**

The **Pixel** class defines a large number of methods. Once you have a reference to a **Pixel** object, you can manipulate the underlying pixel encapsulated in that object in a variety of ways.

Get the pixels in the image

Recall that a reference to the **Picture** object that encapsulates our image is stored in the variable named **pic** . (See Listing 2 (p. 618) .)

Listing 4 (p. 619) begins by calling the **getPixels** method on that reference.

All of the pixels in the image are returned in a one-dimensional array.

A reference to the array is stored in a local reference variable of type **Pixel[]** named **pixelArray** .

A for-each loop

A special kind of **for** loop (*often called a for-each loop*) is used to access and process each pixel in the array. You can learn more about the for-each loop here ²²⁸ . (A conventional **for** loop could also be used here.)

During each iteration of the loop...

The three statements inside the loop modify the red, green, and blue color values of a single pixel.

The first two statements invert the red and green color values by subtracting the values from 255.

²²⁸<http://docs.oracle.com/javase/1.5.0/docs/guide/language/foreach.html>

The third statement in the loop sets the blue color value to zero.

Every pixel in the image will have been modified as described above when the loop terminates.

Not a reversible process

Because the blue color values were set to zero, the image has now been modified in an irreversible manner.

A reversible process

However, if the blue color values had also been inverted, the process would be reversible.

All that would be necessary to recover the original image would be to invert all of the pixels again.

An important process

Color inversion is a very important process in many areas of computing that involve images. The process is:

- Computationally cheap
- Very fast
- Usually visually obvious
- Totally reversible

Often used to highlight selected images

For example, many software program invert all of the colors in an image when it is selected for some purpose, such as copying to the clipboard. Then the colors are restored to their original values when the image is deselected.

Next to redevye correction, color inversion is probably the most commonly used color modification algorithm in use in modern image processing.

Display again and terminate

The variable named `pic` still contains a reference to the original `Picture` object. However, the image that is encapsulated in that object has been significantly modified.

Listing 5 (p. 621) calls the `explore` method again, creating and displaying another `PictureExplorer` object that encapsulates a copy of the `Picture` object with the modified image.

Listing 5 . Display again and terminate.

```

        pic.explore();

    }//end run method
} //end class Prob02Runner

```

Table 3.214

The result is shown in Figure 2 (p. 616) .

The end of the run method

Listing 5 (p. 621) also signals the end of the `run` method and the end of the `Prob02Runner` class.

Return control to main

The `run` method terminates and returns control to the `main` method in Listing 1 (p. 617) .

The code in the `main` method calls a *getter* method to get a reference to the `Picture` object.

The reference is passed to the `println` method, which displays the information about the `Picture` object in the last line of Figure 3 (p. 616) .

The program terminates

Then the `main` method terminates, at which time the program terminates and returns control to the operating system.

3.3.7.4.1 Run the program

I encourage you to copy the code from Listing 6 (p. 624) , compile it and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

You can download a copy of the raw image file here ²²⁹ .

You will learn how to implement a space-wise linear color-modification algorithm in the next module.

- The **explore** method makes it easy to display copies of an image at various stages during the processing of the image. Once the **PictureExplorer** object is created and displayed, it won't be effected by subsequent changes to the image.
- The availability of a **PictureExplorer** object makes it easy to manually analyze the colors of the individual pixels in an image encapsulated in that object.

Answer 4 (p. 631)

3.3.8.3.5 Question 5

True or False? The algorithm shown in Listing 3 (p. 628) can be used to cause the image shown in Figure 2 (p. 631) to be transformed into the image shown in Figure 3 (p. 628) .

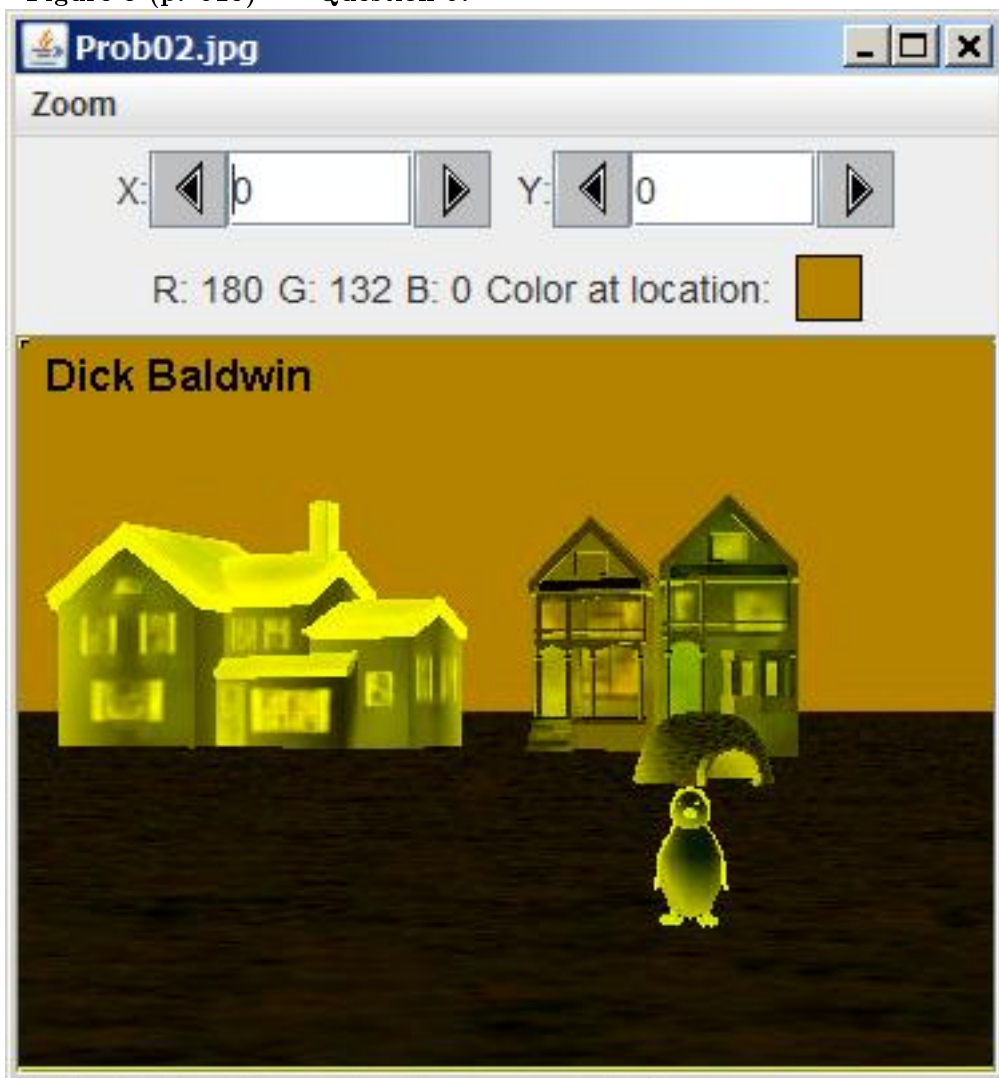

Listing 3 . Question 5.

```
Pixel[] pixelArray = pic.getPixels();

for(Pixel pixel:pixelArray ){
    pixel.setRed(255 - pixel.getRed());
    pixel.setGreen(255 - pixel.getGreen());
    pixel.setBlue(0);
} //end for loop
```

3.3.9.3 Preview

The program that I will explain in this module is designed to be used as a test of the student's understanding of programming using Java and Ericson's media library.

The student is provided an image file named **Prob03.jpg** along with a written specification of a space-wise linear image modification algorithm.

Implement the algorithm

The primary purpose of the test is to determine if the student can implement the algorithm and also satisfy some requirements for text output on the command line screen. Among other things, this requires that the student be able to:

- Create a **Picture** object from an image file.
- Write an *accessor* method to return a reference to the **Picture** object.
- Modify the pixels in the picture according to the specified algorithm.
- Display the raw picture and the modified picture in **PictureExplorer** objects by calling the **explore** method on the **Picture** object before and after it is modified.

The algorithm

Scale the blue and green color components by a scale factor that is less than or equal to 1.0. The green scale factor:

²⁴²<http://cnx.org/content/m44148/latest/>

- Is equal to 1.0 on the left side of the image
- Is equal to 0.0 on the right side of the image
- Decreases linearly with distance going from left to right across the image.

The blue scale factor

- Is 0.0 on the left side of the image
- Is 1.0 on the right side of the image
- Increases linearly with distance going from left to right across the image.

Do not scale the red color component.

The program output

The program produces the images shown in Figure 1 (p. 635) and Figure 2 (p. 635) and produces the output text shown in Figure 3 (p. 636) on the command line screen.

Figure 1 (p. 635) - The raw image.

The required output on the command-line screen is shown by the last two lines of text in Figure 3 (p. 636) . The remaining text in Figure 3 (p. 636) was produced by the system during the compilation and execution process.

3.3.9.4 Discussion and sample code

Will explain in fragments

I will explain this program in fragments. A complete listing is provided in Listing 8 (p. 643) near the end of the module.

I will begin with the driver class named **Prob03** , which is shown in its entirety in Listing 1 (p. 637) .

Listing 1 . The driver class named Prob03.

```
public class Prob03{
public static void main(String[] args){
    Prob03Runner obj = new Prob03Runner();
    obj.run();
    System.out.println(obj.getPicture());
} //end main
} //end class Prob03
```

Table 3.220

There is nothing in Listing 1 (p. 637) that I haven't explained in earlier modules. Therefore, no explanation of the code in Listing 1 (p. 637) should be required.

Beginning of the class named Prob03Runner

The class definition for the class named **Prob03Runner** begins in Listing 2 (p. 637) .

Listing 2 . Beginning of the class named Prob03Runner.

```
class Prob03Runner{
//Instantiate the Picture object.
private Picture pic = new Picture("Prob03.jpg");

public Prob03Runner(){//constructor
    System.out.println("Dick Baldwin");
} //end constructor
//-----//

//Accessor method
public Picture getPicture(){return pic;}
```

Table 3.221

Once again, there is nothing in Listing 2 (p. 637) that I haven't explained before. I included it here simply for the sake of continuity.

The beginning of the run method

The `run` method begins in Listing 3 (p. 638) . The `run` method is where most of the interesting action takes place.

Listing 3 . The beginning of the run method.

```

    public void run(){
    pic.addMessage("Dick Baldwin",10,20);
    //Display a PictureExplorer object.
    pic.explore();

    //Get an array of Pixel objects.
    Pixel[] pixels = pic.getPixels();

    //Declare working variables
    Pixel pixel = null;
    int green = 0;
    int blue = 0;
    int width = pic.getWidth();
    double greenScale = 0;
    double blueScale = 0;

```

Table 3.222

Much of what you see in Listing 3 (p. 638) has been explained in earlier modules. However, Listing 3 (p. 638) does deserve a few comments.

Display the raw image

The call to the `explore` method produces the output shown in Figure 1 (p. 635) .

Get an array of Pixel data

The call to the `getPixels` method in Listing 3 (p. 638) returns a reference to a one-dimensional array object. The elements in the array are references to `Pixel` objects, where each `Pixel` object represents a single pixel in the image. I will explain the organization of the pixel data later ²⁴³ .

Get the width of the image

The call to the `getWidth` method in Listing 3 (p. 638) returns an `int` value that specifies the width of the image in pixels. This value will be used later to compute the column to which each pixel belongs.

Local variables

Listing 3 (p. 638) declares six local variables. The purpose of these variables should become clear during the explanation of the code that implements the algorithm.

Implementation of the algorithm

The algorithm ²⁴⁴ is implemented by the code in a conventional `for` loop, which begins in Listing 4 (p. 639) .

Listing 4 . Beginning of the for loop.*continued on next page*

²⁴³http://cnx.org/content/m44204/latest/Java3006old.htm#Organization_of_the_pixel_data

²⁴⁴http://cnx.org/content/m44204/latest/Java3006old.htm#The_algorithm

```

    for(int cnt = 0;cnt < pixels.length;cnt++){

pixel = pixels[cnt];

green = pixel.getGreen();

blue = pixel.getBlue();

```

Table 3.223

The loop iterates through the array of **Pixel** data, modifying the colors in one pixel during each iteration.

The length property of the array object

Every array object in Java contains a **length** property that contains the number of elements in the array. The value of this property is used in the conditional clause in the **for** loop in Listing 4 (p. 639) to establish when the end of the array has been reached in order to terminate the loop.

Get reference to the next Pixel object

The first statement inside the **for** loop in Listing 4 (p. 639) gets a reference to a **Pixel** object from the next array element. That reference is stored in the local variable of type **Pixel** named **pixel** that was declared in Listing 3 (p. 638) .

Get the red and green color values for the current pixel

Having gotten a reference to the **Pixel** object, the next statement calls the **getGreen** method on that reference to get and save the value of the green color component in the current pixel.

Similarly, the statement following that one gets and saves the value of the blue color component in the current pixel.

Both values are returned as type **int** , and can range in value from 0 up to and including 255.

Objective is to scale the green and blue color values

Recall that the objective is to scale the green and blue color values on a column by column basis, going from left to right across the image shown in Figure 1 (p. 635) in order to produce the output image shown in Figure 2 (p. 635) .

Organization of the pixel data

The pixel data is stored in the array on a row by row basis. In other words, the first **width** elements contain references to pixels in the first row of pixels going from left to right across the screen. The next **width** elements contain references to pixels in the second row of pixels, etc.

Compute the column number and scale factors

Listing 5 (p. 639) uses the modulus operator to compute the column number for each **Pixel** object.

Listing 5 . Compute the column number and scale factors.

```

    //Compute the column number and use it to compute
// the scale factor.
int col = cnt%width;

greenScale = (double)(width - col)/width;
blueScale = (double)(col)/width;

```

Table 3.224

An exercise for the student

Knowing the column number in which the pixel is located, the next step is to compute the green and blue scale factors necessary to satisfy the algorithm.

I will leave it as an exercise for the student to think about how the expressions contained in the last two statements in Listing 5 (p. 639) cause the two scale factors to vary linearly from left to right across the image in accordance with the requirements of the algorithm. (*Think about the equation of a straight line from your high school math classes.*)

Apply the scale factors

The `Pixel` class contains methods named `setRed` , `setGreen` , and `setBlue` that can be called to set the color values for the pixel represented by a `Pixel` object.

Listing 6 (p. 640) computes new values for the red and green components based on the existing color values for the pixel and the scale factors computed in Listing 5 (p. 639) .

Listing 6 . Apply the scale factors.

```

        pixel.setGreen((int)(green * greenScale));
        pixel.setBlue((int)(blue * blueScale));
    }//end for loop

```

Table 3.225

Then Listing 6 (p. 640) calls the `setGreen` and `setBlue` methods on the `Pixel` object to set the green and blue color values to the newly computed values.

The end of the for loop

Listing 6 (p. 640) also signals the end of the `for` loop that began in Listing 4 (p. 639) .

Display the modified image

Finally, Listing 7 (p. 640) calls the `explore` method again to display the image shown in Figure 2 (p. 635) .

Listing 7 . Display the modified image.

```

        pic.explore();

    }//end run method
} //end class Prob03Runner

```

Table 3.226**The end of the run method**

Listing 7 (p. 640) also signals the end of the `run` method and the end of the `Prob03Runner` class.

Return control to main

The `run` method terminates and returns control to the `main` method shown in Listing 1 (p. 637) .

The code in the `main` method calls a *getter* method to get a reference to the `Picture` object.

The reference is passed to the `println` method, which displays the information about the `Picture` object in the last line of Figure 3 (p. 636) .

The program terminates

Then the `main` method terminates, at which time the program terminates and returns control to the operating system.

3.3.9.4.1 Run the program

I encourage you to copy the code from Listing 8 (p. 643) , compile it and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

You can download a copy of the required input image file here ²⁴⁵ .

3.3.9.5 Summary

In this module, I showed you how to implement an algorithm that causes the green and blue color values in an image to change in a linear fashion going from left to right across the image.

3.3.9.6 What's next?

You will learn more about abstract methods, abstract classes, and overridden methods in the next lesson. Very importantly, you will learn more about overriding the `toString` method.

3.3.11.3 Preview

The program that I will explain in this module produces no graphics and does not require the use of Ericson's media library.

OOP concepts

The program illustrates the following OOP concepts:

- Extending an abstract class.
- Parameterized constructor.
- Defining an abstract method in the superclass and overriding it in a subclass.
- Overridden **toString** method.

Program specifications

Write a program named **Prob04** that uses the class definition shown in Listing 1 (p. 654) to produce the output on the command-line screen shown in Figure 1 (p. 653) .

Figure 1 . Program output on the command line screen.
<pre> Prob04 Dick Baldwin 95 95 </pre>

Table 3.229

Pseudo random data

Because the program generates and uses a pseudo random data value each time it is run, the actual values displayed in the last two lines of Figure 1 (p. 653) will differ from one run to the next. However, in all cases, the two values must match.

New classes

You may define new classes as necessary to cause your program to behave as required, but you may not modify the class definition for the class named **Prob04** given below.

3.3.11.4 Discussion and sample code

Will explain in fragments

I will explain this program in fragments. A complete listing is provided in Listing 5 (p. 661) near the end of the module.

I will begin with the driver class named **Prob04** , which is shown in its entirety in Listing 1 (p. 654) .

Listing 1 . Source code for class Prob04.

```
import java.util.*;

abstract class Prob04{
    public static void main(String[] args){
        Random generator = new Random(new Date().getTime());
        int randomNumber = (byte)generator.nextInt();

        Prob04 objRef = new Prob04MyClass(randomNumber);

        System.out.println(objRef);
        System.out.println(objRef.getData());
        System.out.println(randomNumber);
    }//end main

    //Declare the signature of an abstract class.
    public abstract int getData();

} //end class Prob04
```

Table 3.230

The import directive

The import directive at the beginning of Listing 1 (p. 654) is required because the program requires access to the **Random** class and the **Date** class, both of which are defined in the **java.util** package.

Lazy programming practice

It would be better programming practice to provide two explicit import directives, one for the **Random** class and the other for the **Date** class. However, if you are lazy like I apparently was when I wrote this program, you can use the wildcard character (*) to *import* all of the classes in a package.

An abstract method

I'm going to begin by skipping down to the second line from the bottom in Listing 1 (p. 654) and explain the declaration of the *abstract* method named **getData** .

Purpose of an abstract method

The purpose of an abstract method declaration is to establish the signature of a method that must be overridden in every (*non-abstract*) subclass of the class in which the abstract method is declared.

An incomplete method

As you can see the abstract method has no body. Therefore, it is incomplete, has no behavior, and cannot be executed.

An abstract method must be overridden in a subclass in order to be useful.

Override in different ways

The same abstract method can be overridden in different ways in different subclasses. In other words, the behavior of the overridden version can be tailored to (*appropriate for*) the class in which it is overridden.

A guarantee

The existence of an abstract method in a superclass guarantees that every (*non-abstract*) subclass of that superclass will have a **concrete** (*executable*) version of a method having that same signature.

An abstract class

The class named **Prob04** is declared *abstract* in Listing 1 (p. 654) .

Any class can be declared abstract. The consequence of declaring a class abstract is that it is not possible to instantiate an object of the class.

Must be declared abstract...

More importantly, a class must be declared abstract if it contains one or more abstract method declarations. The idea here is that it must not be possible to instantiate objects containing incomplete (*non-executable*) methods.

The main method

As you have seen in previous modules, the driver class for every Java application must contain a method named **main** with a signature matching that shown in Listing 1 (p. 654) .

A pseudo-random number generator

I will leave it as an exercise for the student to go to the javadocs and read up on the class named **Random** , along with the class named **Date** and the method named **getTime** .

Why pseudo-random?

I refer to this as a pseudo-random number generator because the sequence will probably repeat after an extremely large number of values has been generated.

An object of the class Random

Briefly, however, the first statement in the **main** method in Listing 1 (p. 654) instantiates an object that will return a pseudo-random number each time certain methods are called on the object.

Seeding the generator

The value passed as a parameter to the **Random** constructor represents the current time and guarantees that the series of pseudo-random values returned by the methods will be different each time the program is run. This is commonly known as *seeding* the generator.

Get and save a pseudo random value

The next statement in Listing 1 (p. 654) 1 calls the **nextInt** method on the generator object to get and save the next value of type **int** in the pseudo-random sequence.

Cast to type byte

This value is cast to type **byte** , which discards all but the eight least significant bits of the **int** value. When it is stored in the variable named **randomNumber** of type **int** , the sign is extended through the most significant 24 bits and it becomes a value of type **int** that is guaranteed to be of relatively small magnitude.

Why cast to byte?

I cast the random value to type **byte** simply to cause the values that are displayed to be smaller and easier to compare visually.

Instantiate an object of type Prob04MyClass

The next statement in Listing 1 (p. 654) instantiates an object of the class named **Prob04MyClass** , passing the random value as a parameter to the constructor. At this point, I will put the explanation of the class named **Prob04** on temporary hold and explain the class named **Prob04MyClass** , which begins in Listing 2 (p. 656) .

Listing 2 . Beginning of the class named Prob04MyClass.

continued on next page

```

class Prob04MyClass extends Prob04{
private int data;

public Prob04MyClass(int inData){//constructor
    System.out.println("Prob04");
    System.out.println("Dick");
    data = inData;
} //end constructor

```

Table 3.231

Extends the abstract class named Prob04

First note that the class named **Prob04MyClass** extends the abstract class named **Prob04** .

Among other things, this means that either this class must override the abstract method named **getData** that was declared in the superclass, or this class must also be declared abstract.

Does it override getData?

Seeing that this class isn't declared abstract, we can surmise at this point that it does override the abstract method named **getData** . We will see more about this later.

Beginning of the class named Prob04MyClass

The class definition in Listing 2 (p. 656) begins by declaring a private instance variable of type **int** named **data** . Note that it does not initialize the variable. Therefore, the value is automatically initialized to an **int** value of zero.

The constructor

Then Listing 2 (p. 656) defines the constructor for the class. The first two statements in the constructor cause the first two lines of text shown in Figure 1 (p. 653) to be displayed on the command line screen.

Save the incoming parameter value

The last line in the constructor saves the incoming value in the instance variable named **data** , overwriting the default value of zero that it finds there.

This statement is more in keeping with the intended usage of a constructor than the first two statements. The primary purpose of a constructor is to assist in the initialization of the *state of an object* , which depends on the values stored in its variables.

Override the abstract getData method

Listing 3 (p. 656) overrides the abstract **getData** method declared in the abstract superclass named **Prob04** and inherited into the subclass named **Prob04MyClass** .

Listing 3 . Override the abstract getData method.

```

public int getData(){//overridden abstract method
return data;
} //end getData()

```

Table 3.232

Very simple behavior

Although the overridden version of the method simply returns a copy of the value stored in the private instance variable named **data** , it is concrete (p. 655) and can be executed. We will see later that it is called in the **main** method of the driver class named **Prob04** in Listing 1 (p. 654) .

Override the toString method

The ultimate superclass of every class is the predefined system class named **Object** . The **Object** class defines eleven methods with default behavior, including the method named **toString** .

Listing 4 (p. 657) overrides the inherited **toString** method, overriding the default behavior of the method insofar as objects of the class named **Prob04MyClass** are concerned.

Listing 4 . Override the toString method.

```

    public String toString(){//overridden method
    return "Baldwin";
    }//end overloaded toString()

} //end class Prob04MyClass

```

Table 3.233

Default behavior of the toString method

If the **toString** method had not been overridden in the **Prob04MyClass** class, calling the **toString** method on an object of the class would return a string similar to that shown in Figure 2 (p. 657) .

Figure 2 . Default behavior of the toString method .

Prob04MyClass@42e816

Table 3.234

Figure 2 (p. 657) shows the default behavior of the **toString** method as defined in the **Object** class. For this program, only the six hexadecimal digits at the end would change from one run to the next.

More on the default behavior of the toString method

Furthermore, if the **toString** method had not been overridden in the **Prob04MyClass** class, the output produced by the program on the command line screen would be similar to that shown in Figure 3 (p. 657) instead of that shown in Figure 1 (p. 653) .

Figure 3 . More on the default behavior of the toString method.

```

    Prob04
    Dick
    Prob04MyClass@42e816
    -34
    -34

```

Table 3.235

Compare to see the difference

If you compare Figure 3 (p. 657) with Figure 1 (p. 653) , you will see that the difference results from the fact that the overridden version of the `toString` method in Listing 4 (p. 657) returns `"Baldwin"` as a string rather than returning the default string shown in Figure 2 (p. 657) .

The end of the class named `Prob04MyClass`

Listing 4 (p. 657) signals the end of the class definition for the class named `Prob04MyClass` . Therefore, it is time to return to the explanation of the driver class shown in Listing 1 (p. 654) .

Display information about the object

When the `Prob04MyClass` constructor returns, Listing 1 (p. 654) calls the `println` method passing a reference to the new object as a parameter.

Many overloaded (*not overridden*) versions of `println`

There are many overloaded versions of the `println` method, each of which requires a different type of incoming parameter or parameters.

For example, different overloaded versions of the method know how to receive incoming parameters of each of the different primitive types, convert them to characters, and display the characters on the screen.

An incoming parameter of type `Object`

There is also an overloaded version of the `println` method that requires an incoming parameter of type `Object` . That is the version of the method that is executed when the reference to this object is passed to the method in Listing 1 (p. 654) .

One object, several types

Recall that the reference to this object can be treated as its true type, or as the type of any superclass. Therefore, the reference can be treated as any of the following types:

- `Prob04MyClass`
- `Prob04`
- `Object`

Will satisfy type requirement...

Because it can be treated as type `Object` , it will satisfy the type requirement for the overloaded version of the `println` method that requires an incoming parameter of type `Object` .

Call the `toString` method

The first thing that this version of the `println` method does is to call the `toString` method on the incoming reference. Then it displays the string value returned by the `toString` method on the screen.

In this case, the overridden `toString` method returns the string `"Baldwin"` , which is what you see displayed in Figure 1 (p. 653) .

Runtime polymorphism

This is a clear example of an OOP concept known as *runtime polymorphism* .

Runtime polymorphism is much too complicated to explain in this module. However, I explain it in detail here ²⁵⁷ and here ²⁵⁸ . I strongly recommend that you study it there until you thoroughly understand it.

A critical concept

It is critical that you understand runtime polymorphism if you expect to go further in Java OOP.

It is almost impossible to write a useful Java application without making heavy use of runtime polymorphism. That is the foundation of the event driven Java graphical user interface system as well as the collections framework.

Call the overridden `getData` method

The next statement in Listing 1 (p. 654) calls the overridden `getData` method and displays the return value.

As you saw earlier, this method returns a copy of the random value that was received and saved by the constructor for the `Prob04MyClass` class in Listing 2 (p. 656) .

Display the original random value

²⁵⁷ <http://cnx.org/contents/dzOvxPFw:rOlnsVRR>

²⁵⁸ <http://cnx.org/contents/1CVBGBJj>

Finally, the last statement in the **main** method in Listing 1 (p. 654) displays the contents of the instance variable named **randomNumber** . This variable contains the random value that was passed to the constructor for the **Prob04MyClass** earlier in Listing 1 (p. 654) .

The two values must match

Therefore, the final two statements in the **main** method in Listing 1 (p. 654) display the same random value. This is shown in the command line screen output in Figure 1 (p. 653) .

The program terminates

After displaying this value, the **main** method terminates causing the program to terminate.

3.3.11.5 Run the program

I encourage you to copy the code from Listing 5 (p. 661) , compile it and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

3.3.11.6 Summary

You have learned about abstract methods, abstract classes, and overridden methods in this module. Very importantly, you have learned about overriding the **toString** method.

3.3.11.7 What's next?

You will learn more about indirection, array objects, and casting in the next module.

Answer 1 (p. 668)

3.3.12.3.2 Question 2

True or False? The purpose of an abstract method declaration is to establish the signature of a method that must be overridden in a (*non-abstract*) subclass of the class in which the abstract method is declared.

Answer 2 (p. 668)

3.3.12.3.3 Question 3

True or False? When an abstract method is executed, it always exhibits default behavior defined in the class in which it is declared.

Answer 3 (p. 667)

3.3.12.3.4 Question 4

True or False? An abstract method must be overridden in a subclass in order to be executed.

Answer 4 (p. 667)

3.3.12.3.5 Question 5

True or False? An abstract method can be overridden once and once only and it must be overridden in the immediate subclass of the class in which it is declared.

Answer 5 (p. 667)

3.3.12.3.6 Question 6

True or False? The existence of an abstract method in a superclass guarantees that objects instantiated from every (*non-abstract*) subclass of that superclass will have a **concrete** (*executable*) version of a method having that same signature.

Answer 6 (p. 667)

3.3.12.3.7 Question 7

True or False? Any class can be declared abstract. The consequence of declaring a class abstract is that it is not possible to instantiate an object of the class.

Answer 7 (p. 667)

3.3.12.3.8 Question 8

True or False? A class must be declared abstract if it contains two or more abstract method declarations.

Answer 8 (p. 667)

3.3.12.3.9 Question 9

True or False? If a class inherits an abstract method, either the subclass must be declared abstract, or it must provide a concrete overridden version of the inherited abstract method.

Answer 9 (p. 667)

3.3.12.3.10 Question 10

True or False? The primary purpose of a constructor is to assist in the initialization of the *state of an object*, which depends on the values stored in its variables.

Answer 10 (p. 667)

3.3.12.3.11 Question 11

True or False? The default version of the `toString` method is defined in the class named `Class`.

Answer 11 (p. 667)

3.3.12.3.12 Question 12

True or False? There is an overloaded version of the `println` method that requires an incoming parameter of type `Object`. When that version of the method is called, it calls the `toString` method on the incoming object reference and displays the string that is returned by the `toString` method. If the `toString` method belonging to the object has not been overridden, the default version of the `toString` method will be executed and the string that will be displayed is the string returned by that default version. The `toString` method can be overridden to cause the string that is displayed to be more appropriate for the object. The `toString` method can be overridden only once in the class hierarchy.

3.3.13.3 Preview

The program that I will explain in this module produces no graphics and does not require the use of Ericson's media library.

OOP concepts

The program illustrates the following OOP concepts among others:

- Multiple levels of indirection
- A one-element array of type **Object**
- Storing a reference to an object in an array element as type **Object**
- An anonymous object
- Passing a reference to a subclass object as type **Object**
- Downcasting an incoming object reference to access a method

Program specifications

Write a program named **Prob05** that uses the class definition shown in Listing 1 (p. 670) to produce an output similar to that shown in Figure 1 (p. 670) on the command-line screen.

Figure 1 . Program output on command line screen.
<pre> Prob05 Dick Baldwin -28 -28 </pre>

Table 3.240

A random value

Because the program generates and uses a random data value, the actual values displayed will differ from one run to the next. However, in all cases, the two values shown in Figure 1 (p. 670) must match.

New classes

You may define new classes as necessary to cause your program to behave as required, but you may not modify the class definition for the class named **Prob05** which begins in Listing 1 (p. 670) .

3.3.13.4 Discussion and sample code

Will explain in fragments

I will explain this program in fragments. A complete listing is provided in Listing 6 (p. 677) near the end of the module.

I will begin with the driver class named **Prob05** , which begins in Listing 1 (p. 670) .

Listing 1 . Beginning of the Prob05 class.
<i>continued on next page</i>

```

import java.util.*;

class Prob05{
    public static void main(String[] args){

        Random generator = new Random(new Date().getTime());
        int randomNumber = (byte)generator.nextInt();

        Object[] objRef = {new Prob05MyClassA(randomNumber)};
    }
}

```

Table 3.241

Everything in Listing 1 (p. 670) should be familiar to you with the possible exception of the last statement, which I will explain shortly.

Characteristics of arrays in Java

Before explaining that statement, however, I will discuss some of the important characteristics of array objects in Java. A list of such characteristics follows in no particular order:

- All arrays in Java are one-dimensional arrays. (*Multidimensional arrays are created by creating tree structures of one-dimensional arrays.*)
- Each array in Java is encapsulated in a special type of object that I will refer to as an *array object*.
- As with all objects, an array object must be accessed using a reference to the array object.
- When the declared type of an array is one of the eight primitive types, the actual values are stored in the array elements in the array object.
- When the declared type of an array is the type of an object (*array object or ordinary object*), references to the objects are stored in the array elements and the objects actually exist elsewhere in memory.
- As with instance variables, the elements in an array are typically initialized with the standard default values for the types involved (*zero, false, or null*). That is not the case in this program however.
- The array that is encapsulated in an array object may have none, one, or more elements. (*Yes, it is possible for a Java array to have no elements, but that normally occurs only in special circumstances.*)
- The **length** or size of the array is established when the array object is instantiated and cannot be changed thereafter.
- Every array object contains a special property named **length** that contains the number of elements in an array. It is always possible to determine the number of elements in an array object at runtime by accessing the value of the **length** property for the array object.

A special instantiation syntax

There is a special syntax that allows for the instantiation of an array object and the initialization of the array elements in a single statement. (*I explain this here ²⁷¹, here ²⁷², and here ²⁷³ so you should already know all about it.*) The **last statement** in Listing 1 (p. 670) is an example of this syntax.

Briefly, the syntax consists of a comma separated list of element values (*expressions*) inside a pair of matching curly braces. The **length** of the array is determined by the number of values in the list. The type of the array is determined by the types of the elements in the list.

This syntax instantiates an array object of the correct **length** and populates the elements with the specified values.

A reference is returned

²⁷¹<http://cnx.org/contents/1CVBGBJ:Fj8xxCSh>

²⁷²http://cnx.org/contents/dzOvxPFw:XQBfo3b_

²⁷³<http://cnx.org/contents/EHRr6hjR:LYyIoCvP>

A reference to the array object is returned in much the same way that a constructor for an ordinary object returns a reference to the object.

As is always the case, if the reference is stored in a variable, the type of the reference must be *assignment compatible* with the type of the variable.

What is assignment compatible?

If you have forgotten what this term means, I recommend that you go to Google and search for the following keywords to learn more about it:

site:<http://cnx.org/contents/> "assignment compatible" java

A one-element array

The last statement in Listing 1 (p. 670) instantiates an array object containing a one-element array. The array element is initialized with a reference to a new object of type **Prob05MyClassA**, which exists somewhere else in memory.

The value of a random number that was generated earlier in the **main** method is passed as a parameter to the constructor for the object of type **Prob05MyClassA**.

Save the reference to the array object

The reference to the array object is stored in the local reference variable named **objRef** of type **Object**. We know that the reference is *assignment compatible* with this reference variable because the **Object** type is completely generic. All non-primitive types are assignment compatible with type **Object**.

The class named Prob05MyClassA

At this point, I am going to put the explanation of the class named **Prob05** temporarily on hold and explain the class named **Prob05MyClassA**, which is shown in its entirety in Listing 2 (p. 672).

Listing 2 . The class named Prob05MyClassA.

```
class Prob05MyClassA extends Prob05{
private int data;

public Prob05MyClassA(int inData){
    System.out.println("Prob05");
    System.out.println("Dick");
    data = inData;
} //end constructor

public int getData(){
    return data;
} //end getData()

} //end class Prob05MyClassA
```

Table 3.242

Note that the class named **Prob05MyClassA** extends the class named **Prob05**, which is partially shown in Listing 1 (p. 670).

Familiar code

All of the code in Listing 2 (p. 672) should be familiar to you because it is very similar to the code in the previous module. Therefore, no explanation of Listing 2 (p. 672) is warranted.

Save the incoming value

In summary, when the object of type **Prob05MyClassA** is instantiated, it saves the value of an incoming constructor parameter in a private instance variable.

Return the saved value

When the method named **getData** is called on a reference to the object, it returns a copy of that value.

A review

To review what I have already said, the array object that was instantiated in Listing 1 (p. 670) contains a reference to this object of type **Prob05MyClassA** in the only element of the one-element array.

The reference to the array object is stored in the reference variable named **objRef** .

Indirection at work

At this point, **objRef** contains a reference to an array object, one element of which contains a reference to an ordinary object, which is located somewhere else in memory. This is indirection.

The next statement in the main method

Returning now to the **main** method that began in Listing 1 (p. 670) , Listing 3 (p. 673) shows the next statement in the **main** method following the last statement in Listing 1 (p. 670) .

Listing 3 . The next statement in the main method.

```
System.out.println(
    new Prob05MyClassB().getDataFromObj(objRef[0]));
```

Table 3.243

What is an anonymous object?

An anonymous object is an object whose reference is not saved in a named reference variable.

Instantiate an anonymous object

Consider the parameter list of the **println** method shown in Listing 3 (p. 673) . A new object of the **Prob05MyClassB** class is instantiated in the parameter list. However, the reference to that object is not saved in a named reference variable. Instead, that reference is used to immediately call the method named **getDataFromObj** that belongs to the anonymous object.

The parameter that is passed...

Now consider the parameter that is passed to the method named **getDataFromObj** . The expression inside that parameter list extracts the contents of the zeroth element in the array object that is referred to by the contents of the variable named **objRef** .

And those contents are...

That element contains a reference to an object of the class **Prob05MyClassA** (see Listing 1 (p. 670)) .

Therefore, a reference to an object of type **Prob05MyClassA** is passed as a parameter to the method named **getDataFromObj** .

The class named Prob05MyClassB

It is time to take a look at the class in which the **getDataFromObj** method is defined.

The class named **Prob05MyClassB** is shown in its entirety in Listing 4 (p. 674) .

Listing 4 . The class named Prob05MyClassB.

continued on next page

```

class Prob05MyClassB{

Prob05MyClassB(){
    System.out.println("Baldwin");
} //end constructor

public int getDataFromObj(Object refToObj){
    return ((Prob05MyClassA)refToObj).getData();
} //end getDataFromObj()

} //end class Prob05MyClassB

```

Table 3.244

Extends the Object class

Note that this class does not extend the class named **Prob05** . In fact, it doesn't explicitly extend any class. This means that it extends the class named **Object** by default because every class is a subclass of the class named **Object** .

The constructor

The constructor for this class is inconsequential. It simply displays my last name when the object is instantiated, producing part of the output text shown in Figure 1 (p. 670) .

The getDataFromObj method

The interesting part of Listing 4 (p. 674) is the definition of the method named **getDataFromObj** .

As we saw before, this method receives a reference to an object of type **Prob05MyClassA** (see Listing 3 (p. 673)) . However, this reference is not received as the true type of the object. Instead, it is received as type **Object** , which is the ultimate superclass of the class named **Prob05MyClassA** .

The objective of the method

The objective is to call the method named **getData** on the incoming reference. However, the **Object** class doesn't know anything about a method named **getData** because the **Object** class neither defines nor inherits a method having that signature. Instead, the **getData** method is defined in the class named **Prob05MyClassA** , which is the true type of the object.

A cast is required

Therefore, it is necessary to convert the type of the reference back to its true type using a cast operator before that reference can be used to call the method named **getData** . (The cast operator is shown in Listing 4 (p. 674) .)

The returned value

The **getData** method returns a copy of the value that was passed as a constructor parameter when the object was instantiated. (See Listing 2 (p. 672) .) Recall that the value was the original random value. (See Listing 1 (p. 670) .)

Referring back to Listing 4 (p. 674) , that is the value that is returned from the call to the **getDataFromObj** method in Listing 3 (p. 673) , which cause the value to be displayed as the first numeric value in Figure 1 (p. 670) .

The end of the main method

Returning once more to the **main** method and picking up where we left off in Listing 3 (p. 673) , Listing 5 (p. 675) shows the final statement in the **main** method.

Listing 5 . The end of the main method.

```

        System.out.println(randomNumber);

    }//end main
} //end class Prob05

```

Table 3.245

This statement simply displays the original random value that was passed to the constructor for the **Prob05MyClassA** in Listing 1 (p. 670) . This statement displays the second numeric value shown as the last line of text in Figure 1 (p. 670) .

The end of the program

At this point, the **main** method terminates causing the program to terminate.

3.3.13.5 Run the program

I encourage you to copy the code from Listing 6 (p. 677) , compile it and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

The program described in this module requires the use of the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library ²⁸⁵.

3.3.15.3 Preview

In this module, you will learn how to use nested **for** loops to process pixels on a row and column basis.

Program specifications

Write a program named **Prob01** that uses the class definition shown in Listing 1 (p. 692) along with Ericson's media library and the image file named **Prob01.jpg** to produce the graphic output images shown in Figure 1 (p. 690) and Figure 2 (p. 690).

Figure 1 (p. 690) - Raw image.

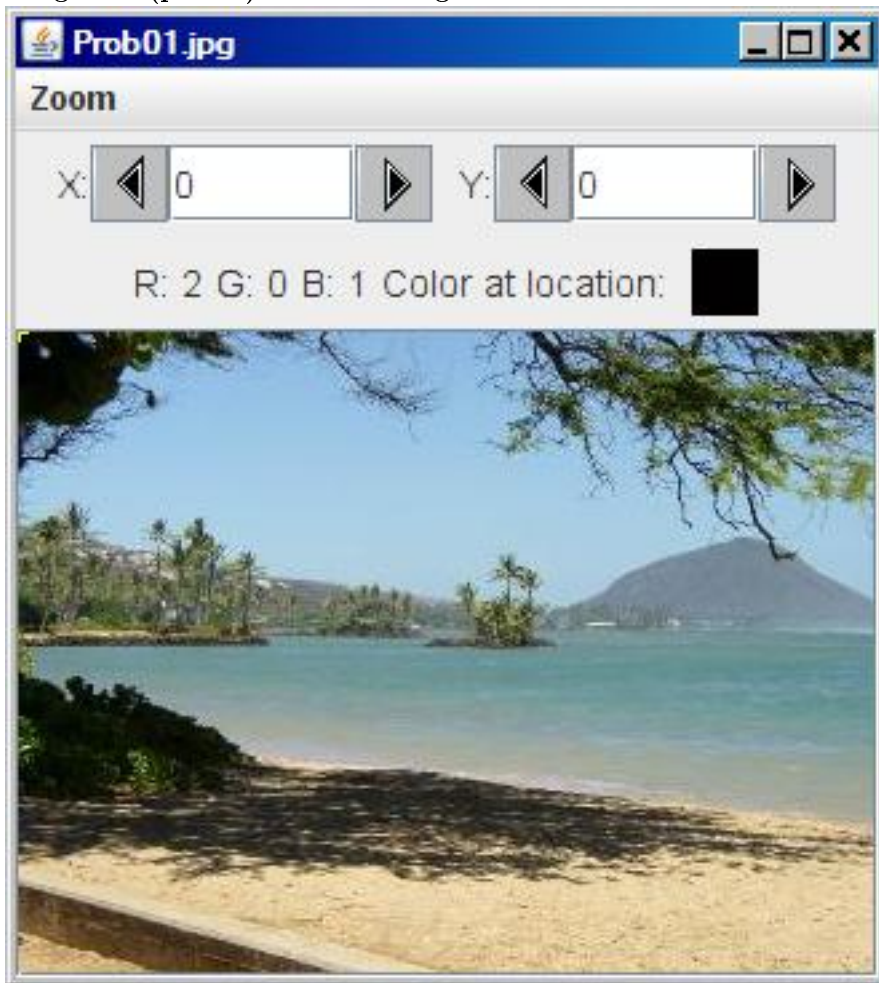

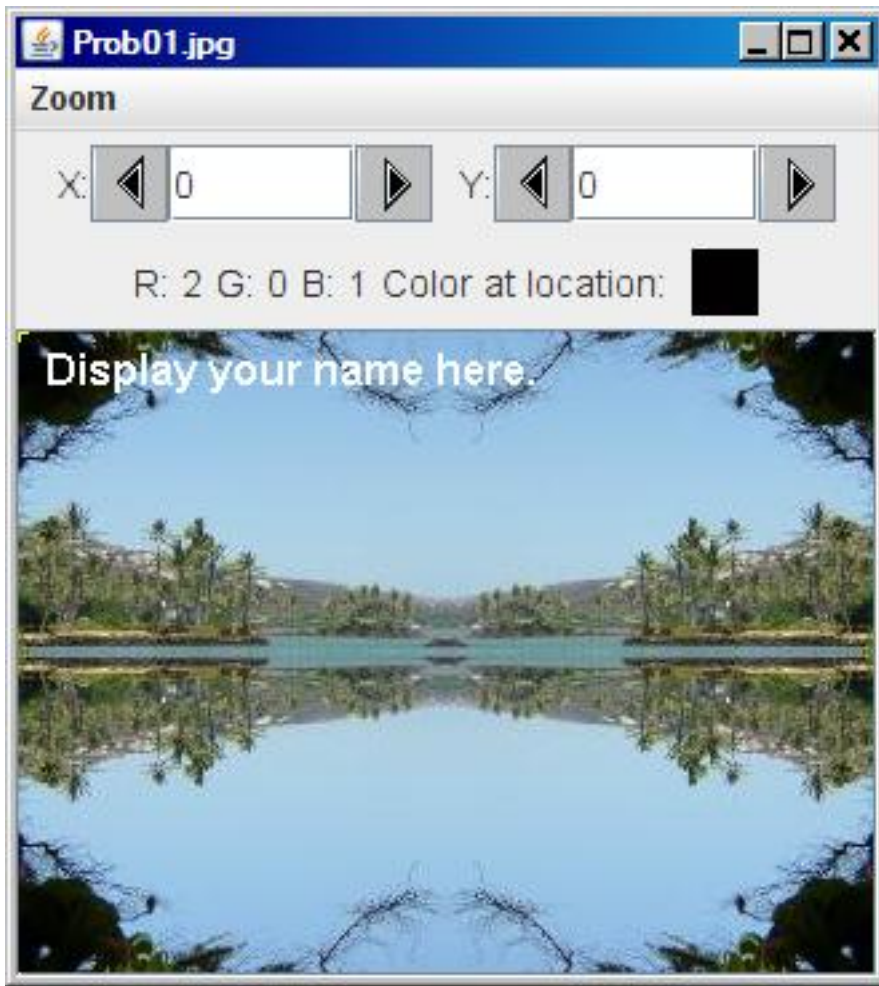

Figure 2 (p. 690) - Modified image.

Define new classes

You may define new classes as necessary to cause your program to behave as required, but you may not modify the class definition for the class named **Prob01** given in Listing 1 (p. 692) .

Required text output

In addition to the two output images mentioned above, your program must display your name and the other line of text shown in Figure 3 (p. 691) on the command-line screen.

Figure 3 . Required text output.

```

Display your name here.
Picture, filename Prob01.jpg height 240 width 320

```

Table 3.254

3.3.15.3.1 General background information

This program mirrors an image in such a way that the image in each quadrant is a mirror image of the image in the two adjacent quadrants as shown in Figure 2 (p. 690) .

The top left quadrant is mirrored into the top right quadrant, and then the top half is mirrored into the bottom half.

Major evaluation areas

In order to successfully write this program, the student must be able to:

- Examine the input and output images and determine how the input image has been modified to produce the output image.
- Manipulate the individual pixels in the image to perform the required modifications.

3.3.15.4 Discussion and sample code

Will discuss in fragments

I will discuss this program in fragments. A complete listing of the program is provided in Listing 8 (p. 699) near the end of the module.

The driver class named Prob01

The driver class containing the `main` method is shown in Listing 1 (p. 692) .

Listing 1 . The driver class named Prob01.

```
public class Prob01{
public static void main(String[] args){
    Picture pic = new Prob01Runner().run();
    System.out.println(pic);
} //end main method
} //end class Prob01
```

Table 3.255

There is nothing in Listing 1 (p. 692) that I haven't explained in earlier modules.

The `println` statement in Listing 1 (p. 692) causes the second line of text to be displayed in Figure 3 (p. 691) .

The constructor for the class named Prob01Runner

The constructor for the class named `Prob01Runner` is shown in Listing 2 (p. 692) .

Listing 2 . The constructor for the class named Prob01Runner .

```
class Prob01Runner{
public Prob01Runner(){
    System.out.println("Display your name here.");
} //end constructor
```

Table 3.256

The code in Listing 2 (p. 692) simply causes the first line of text in Figure 3 (p. 691) to be displayed on the command line screen.

Beginning of the method named run

The code in the driver class in Listing 1 (p. 692) instantiates a new object of the **Prob01Runner** class and immediately calls the **run** method belonging to that object. The **run** method begins in Listing 3 (p. 693).

Listing 3 . Beginning of the method named run.

```
public Picture run(){
    Picture pix = new Picture("Prob01.jpg");

    //Display the input picture.
    pix.explore();

    //Call the mirrorUpperQuads method to modify the top
    // half of the picture.
    pix = mirrorUpperQuads(pix);
}
```

Table 3.257

A new Picture object

Listing 3 (p. 693) instantiates a new **Picture** object from an image file and saves a reference to that object in the local variable named **pix**.

Display the Picture object

Then Listing 3 (p. 693) calls the **explore** method on the reference producing the output image shown in Figure 1 (p. 690).

Modify top half of the picture

Finally, Listing 3 (p. 693) calls the method named **mirrorUpperQuads** to mirror the upper-left quadrant of the picture into the upper-right quadrant. A copy of a reference to the picture object is passed to the method and the value returned by the method is saved in the variable named **pix**. (*I will have more to say about this later.*)

Put the explanation of the run method on hold

I will put the explanation of the **run** method on hold temporarily and explain the method named **mirrorUpperQuads**.

Beginning of the mirrorUpperQuads method

The beginning of the **mirrorUpperQuads** method is shown in Listing 4 (p. 693).

Listing 4 . Beginning of the mirrorUpperQuads method.

```
private Picture mirrorUpperQuads(Picture pix){
    Pixel leftPixel = null;
    Pixel rightPixel = null;

    int midpoint = pix.getWidth()/2;
    int width = pix.getWidth();
}
```

Table 3.258

Note that the method receives a copy of a reference to the picture.

Declare working variables

The code in Listing 4 (p. 693) begins by declaring a pair of local working variables of type `Pixel`. These variables will be used to hold information about individual pixels.

Compute width and midpoint of the image

Then Listing 4 (p. 693) computes and saves the width and the horizontal midpoint of the image.

Mirror pixel colors around the midpoint

Listing 5 (p. 694) uses a pair of nested `for` loops to copy the pixel colors on the left of the midpoint to corresponding mirror-image pixels on the right side of the midpoint.

Listing 5 . Mirror pixel colors around the midpoint.

```

    for(int row = 0;row < pix.getHeight()/2;row++){
    for(int col = 0;col < midpoint;col++){
        leftPixel = pix.getPixel(col,row);
        rightPixel = pix.getPixel(width-1-col,row);
        rightPixel.setColor(leftPixel.getColor());
    }//end inner loop
    }//end outer loop

    return pix;
} //end mirrorUpperQuads

```

Table 3.259

Iterate on rows and columns

The outer loop in Listing 5 (p. 694) iterates down through each of the rows in the top half of the image. The inner loop iterates across the left half of each row, copying the color of the pixels from the left half to the corresponding mirror-image pixels on the right half.

Note that the `getPixel` method that is called in Listing 5 (p. 694) is different from the `getPixels` method that was explained in several earlier pages in this book. You can easily find those references by entering the term `getPixels` in the search box at the top of this page that reads *"Search this book."* I will leave it as an exercise for the student to go to the documentation and learn the difference between these two methods.

Return a reference to the modified object

Finally, Listing 5 (p. 694) returns a reference to the modified `Picture` object. The reference is assigned to the variable named `pix` in Listing 3 (p. 693).

Superfluous but self-documenting code

Returning and storing a reference to the modified picture is superfluous and unnecessary. The code in Listing 3 (p. 693) already has a reference to the picture and that reference doesn't change just because the object to which it refers is modified.

However, I prefer this programming style because I consider it to be more self-documenting.

Remainder of the run method

Returning now to the `run` method, Listing 6 (p. 695) calls the method named `mirrorHoriz` to mirror the top half of the image into the bottom half. (*I will explain the `mirrorHoriz` method shortly.*)

Listing 6 . Remainder of the run method.

```

    //Mirror the top half into the bottom half.
    pix = mirrorHoriz(pix);

    //Add your name and display the output picture.
    pix.addMessage("Display your name here.",10,20);

    pix.explore();

    return pix;

} //end run

```

Table 3.260**Display text on the image**

Then Listing 6 (p. 695) calls the **addMessage** method on the reference to the picture to place the text near the upper-left corner as shown in Figure 2 (p. 690) .

Display the modified image

After that, Listing 6 (p. 695) calls the **explore** method to display the modified image as shown in Figure 2 (p. 690) .

Return a reference to the modified picture

Finally, Listing 6 (p. 695) returns the reference to the modified picture, which is saved in the variable named **pic** in Listing 1 (p. 692) .

As mentioned earlier, the variable named **pic** is passed to the **println** method in Listing 1 (p. 692) , causing the second line of text shown in Figure 3 (p. 691) to be displayed on the command line screen.

The method named mirrorHoriz

Listing 7 (p. 696) shows the method named **mirrorHoriz** in its entirety. This method mirrors the top half of the picture into the bottom half.

Listing 7 . The method named mirrorHoriz.

```

    private Picture mirrorHoriz(Picture pix){
    Pixel topPixel = null;
    Pixel bottomPixel = null;

    int midpoint = pix.getHeight()/2;
    int height = pix.getHeight();

    for(int col = 0;col < pix.getWidth();col++){
        for(int row = 0;row < midpoint;row++){
            topPixel = pix.getPixel(col,row);
            bottomPixel =
                pix.getPixel(col,height-1-row);
            bottomPixel.setColor(topPixel.getColor());
        }//end inner loop
    }//end outer loop

    return pix;
    }//end mirrorHoriz
    //-----//

} //end class Prob01Runner

```

Table 3.261**Very similar to an earlier method**

This method is very similar to the method named **mirrorUpperQuads** that I explained in Listing 4 (p. 693) and Listing 5 (p. 694) . If you understood that explanation, you should have no difficulty understanding the code in Listing 7 (p. 696) without further explanation.

End of Prob01Runner class

Listing 7 (p. 696) also signals the end of the class named **Prob01Runner** .

3.3.15.4.1 Run the program

I encourage you to copy the code from Listing 8 (p. 699) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

3.3.16.6 Answers

3.3.16.6.1 Answer 4

False. The code in Listing 3 (p. 705) has the wrong spelling for the method that returns the **Pixel** object. The correct spelling is shown in Listing 4 (p. 707) . You learned about the spelling (*with no parameters*) shown in Listing 3 (p. 705) in an earlier module.

Listing 4 . Answer 4.
<pre>leftPixel = pix.getPixel(col,row);</pre>

Table 3.266

Back to Question 4 (p. 705)

3.3.16.6.2 Answer 3

True. The object instantiated from the class named **Java3012raRunner** is an anonymous object because its reference is not saved in a named reference variable in the current scope. Anonymous classes and anonymous objects are entirely different topics.

Back to Question 3 (p. 705)

3.3.16.6.3 Answer 2

False. A discussion of anonymous classes would be a somewhat advanced topic. That topic is not explained in the module named Java3012: Using Nested Loops to Process Pixels ²⁹⁴ .

Back to Question 2 (p. 704)

3.3.16.6.4 Answer 1

True.

3.3.17.3 Preview

In this module, you will learn how to:

- Work directly with individual pixels and keep track of coordinate values.
- Copy a portion of one picture into a specific location in another picture.
- Crop and flip a picture.

Program specifications

Write a program named **Prob02** that uses the class definition shown in Listing 1 (p. 713) and Ericson's media library along with the image files named **Prob02a.jpg** and **Prob02b.jpg** to produce the three graphic output images shown in Figure 1 (p. 709) , Figure 2 (p. 710) , and Figure 3 (p. 711) .

Figure 1 (p. 709) - Raw butterfly image.

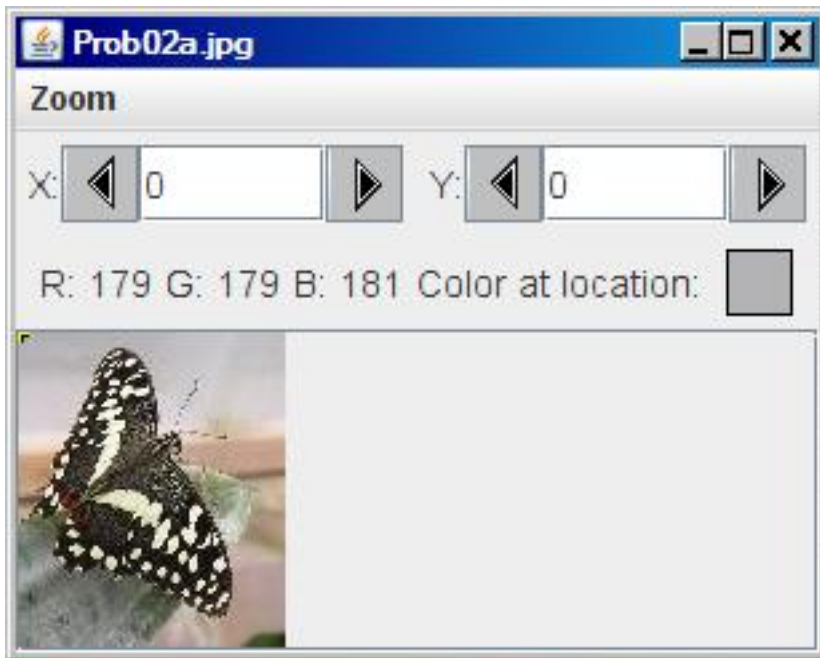

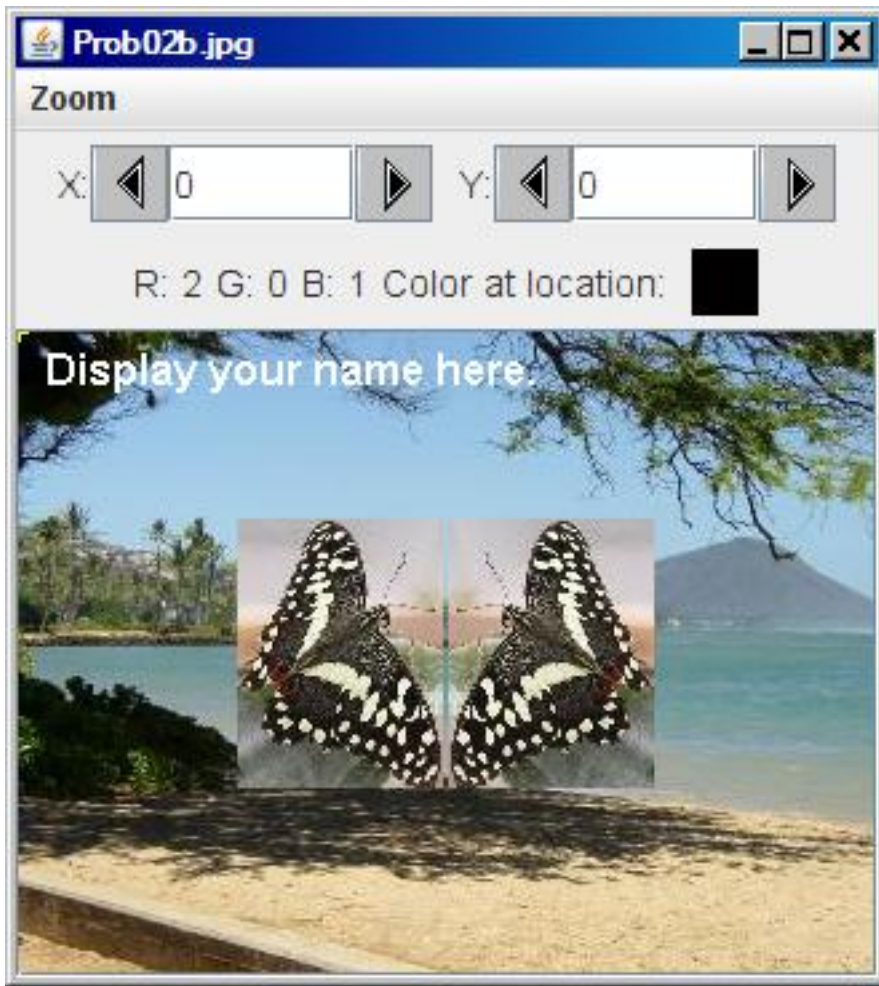

Figure 2 (p. 710) - Beach scene with student's name added.

Figure 3 (p. 711) - Composite image.

May define new classes

You may define new classes as necessary to cause your program to behave as required, but you may not modify the class definition for the class named **Prob02** given in Listing 1 (p. 713) .

The facing butterfly images

The two facing images of the butterflies in the final output picture are separated by two pixels and those two images as a pair are centered in the picture of the beach.

Required text output

In addition to the three output images mentioned above, your program must display your name and the other three lines of text shown in Figure 4 (p. 712) on the command-line screen:

Figure 4 . Required text output.

```

Display your name here.
Picture, filename Prob02a.jpg height 118 width 100
Picture, filename Prob02b.jpg height 240 width 320
Picture, filename None height 101 width 77

```

Table 3.267

3.3.17.4 General background information

This program copies a rectangular portion of a picture of a butterfly into a specific location in a picture of a beach.

The program also crops the butterfly picture to the same size as the portion that was copied into the beach picture and flips the cropped version to cause the butterfly to face left instead of facing right.

Then it copies the cropped and flipped image to a location two pixels to the right of the original copy of the butterfly in the beach image.

The two resulting images of the butterfly within the beach image are separated by two pixels, face one another, and are centered in the picture of the beach as shown in Figure 3 (p. 711) .

Major evaluation areas

In order to successfully write this program, the student must, as a minimum be able to:

- Work directly with individual pixels and keep track of coordinate values.
- Copy a portion of one picture into a specific location in another picture.
- Crop and flip a picture.

3.3.17.5 Discussion and sample code

Will discuss in fragments

I will discuss this program in fragments. A complete listing of the program is provided in Listing 10 (p. 723) near the end of the module.

The driver class named Prob02

The driver class containing the `main` method is shown in Listing 1 (p. 713) .

Listing 1 . The driver class named Prob02.

```
import java.awt.Color;

public class Prob02{
    public static void main(String[] args){
        Picture[] pictures = new Prob02Runner().run();

        System.out.println(pictures[0]);
        System.out.println(pictures[1]);
        System.out.println(pictures[2]);
    } //end main method
} //end class Prob02
```

Table 3.268

A reference to an array object

The call to the `run` method in Listing 1 (p. 713) may be new to you. This call expects to receive a reference to an array object of type `Picture[]` as a return value.

Save return value in variable named pictures

The return value from the `run` method is stored in the local reference variable named `pictures` .

Extract and print references to Picture objects

Then the reference variable is used to extract references to the individual `Picture` objects encapsulated in the array. Those references are passed to the `println` method causing the last three lines of text shown in Figure 4 (p. 712) to be displayed on the command line screen.

Beginning of the Prob02Runner class

The class named **Prob02Runner** begins in Listing 2 (p. 714) , which shows the constructor for the class.

Listing 2 . Beginning of the Prob02Runner class.

```
class Prob02Runner{

public Prob02Runner(){//constructor
    System.out.println("Display your name here.");
} //end constructor
```

Table 3.269

The constructor simply causes the student's name to be displayed on the command line screen, producing the first line of output text shown in Figure 4 (p. 712) .

Beginning of the run method

The **run** method, that was called in Listing 1 (p. 713) begins in Listing 3 (p. 714) .

Listing 3 . Beginning of the run method.

```
public Picture[] run(){
Picture picA = new Picture("Prob02a.jpg");
picA.explore();

Picture picB = new Picture("Prob02b.jpg");
picB.addMessage("Display your name here.",10,20);
picB.explore();

Picture picC = cropAndFlip(picA,4,5,80,105);
```

Table 3.270

Listing 3 (p. 714) instantiates two **Picture** objects from image files and displays them by calling the **explore** method on each **Picture** object. In addition, the student's name is added near the upper-left corner of the beach image. This code results in the images shown in Figure 1 (p. 709) and Figure 2 (p. 710) .

Call the cropAndFlip method

Then Listing 3 (p. 714) calls the **cropAndFlip** method passing the reference to the butterfly image of Figure 1 (p. 709) , along with some other information as parameters. The return value is stored in a new local reference variable of type **Picture** named **picC** .

Put discussion of the run method on hold

I will put the discussion of the **run** method on temporary hold at this point and explain the method named **cropAndFlip** , which begins in Listing 4 (p. 715) .

Beginning of the cropAndFlip method

The **cropAndFlip** method crops a picture to the specified coordinate values and flips it around a vertical line at its center.

Listing 4 . Beginning of the cropAndFlip method.

```
private Picture cropAndFlip(Picture pic,
    int x1,int y1,
    int x2,int y2){
    Picture output = new Picture(x2-x1+1,y2-y1+1);

    int width = output.getWidth();

    Pixel pixel = null;
    Color color = null;
```

Table 3.271**Incoming parameters**

In addition to a reference to the picture to be processed, the method receives four incoming integer values as parameters. The parameters named **x1** and **y1** specify the coordinates of the upper-left corner of a rectangular area of the picture that is to be retained in the output.

The parameters named **x2** and **y2** specify the coordinates of the lower-right corner of the rectangular area of the picture that is to be retained in the output.

An empty Picture object

Listing 4 (p. 715) begins by creating an empty **Picture** object of the correct size to hold the cropped image. A reference to the empty picture is saved in the local reference variable named **output** .

Then Listing 4 (p. 715) gets and saves the width of the output picture.

Following this, Listing 4 (p. 715) declares two local working variables named **pixel** (of type **Pixel**) and **color** (of type **Color**) .

Process using nested loops

Listing 5 (p. 715) uses a pair of nested **for** loops to cause the output picture to be a cropped version of the picture received as an incoming parameter. The cropped image is flipped around its center.

Listing 5 . Process using nested loops.

```
    for(int col = x1;col < (x2+1);col++){
    for(int row = y1;row < (y2+1);row++){
        color = pic.getPixel(col,row).getColor();
        pixel = output.getPixel(width-col+x1-1,row-y1);
        pixel.setColor(color);
    }//end inner loop
    }//end outer loop

    return output;
} //end cropAndFlip method
```

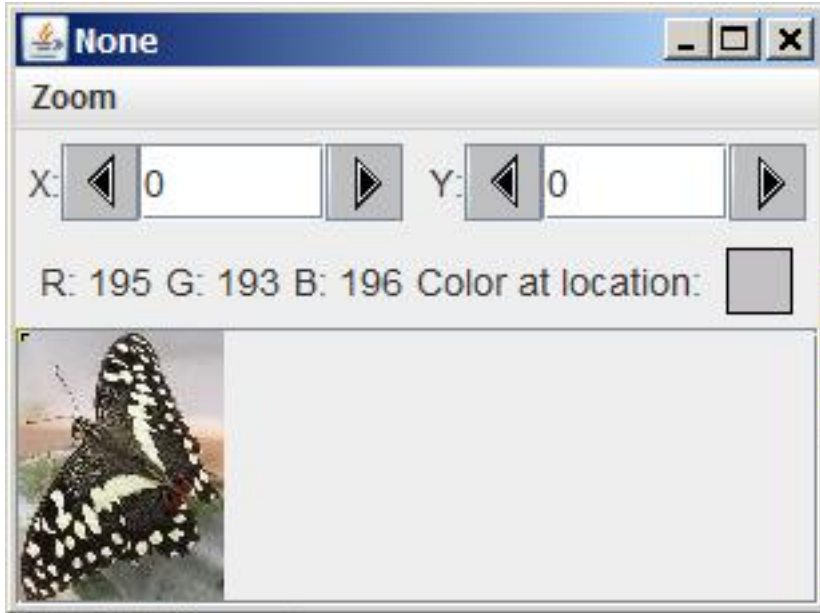

Table 3.272

The code in Listing 5 (p. 715) copies the pixel colors of the selected pixels of the incoming image to the pixels of the output image, flipping the image around its center line in the process.

Cropped and flipped version of the butterfly image

If you display the picture referred to by **output** in Listing 5 (p. 715) , you will get the image shown in Figure 5 (p. 716) .

Figure 5 (p. 716) - Cropped and flipped version of the butterfly image.

Compare with the original butterfly picture

If you compare Figure 5 (p. 716) with Figure 1 (p. 709) , you will see that pixels on the outer edges of Figure 1 (p. 709) have been discarded and the resulting image has been flipped around its centerline.

End of the `cropAndFlip` method

Figure 5 (p. 716) returns a reference to the new image and ends the method named `cropAndFlip` . The returned value is stored in the variable named `picC` in Listing 3 (p. 714) .

Original image not modified

Note that the code in the `cropAndFlip` method does not modify the original image of the butterfly. Instead, it extracts pixel data from the original image to produce a new image. When control returns to the `run` method in Listing 3 (p. 714) , a reference to the new image is stored in the variable named `picC` .

Call the `copyPictureWithCrop` method from the `run` method

Control has now returned to the `run` method, picking up where Listing 3 (p. 714) left off. The next statement in the `run` method is shown in Listing 6 (p. 716) .

Listing 6 . Call the `copyPictureWithCrop` method from the `run` method.

```
copyPictureWithCrop(picA,picB,82,70,4,5,77,101);
```

Table 3.273

Put the `run` method on hold again

Once again, I will put the `run` method on hold while I explain the method named `copyPictureWithCrop` , which begins in Listing 7 (p. 717) .

Beginning of the method named `copyPictureWithCrop`

The first two incoming parameters named **source** and **dest** are references to a source picture and a destination picture.

When the method is called in Listing 6 (p. 716) , the source picture is the original butterfly picture shown in Figure 1 (p. 709) and the destination picture is the beach picture shown in Figure 2 (p. 710) .

Listing 7 . Beginning of the method named copyPictureWithCrop.

```
private void copyPictureWithCrop(
    Picture source,
    Picture dest,
    int xOff,
    int yOff,
    int xCoor,
    int yCoor,
    int width,
    int height){

    //Confirm that source will fit in destination
    if(((width+xOff) <= dest.getWidth()) &&
        ((height+yOff) <= dest.getHeight())){

        Pixel pixel = null;
        Color color = null;
```

Table 3.274

Copy source to destination

The method named **copyPictureWithCrop** copies part of the source picture into the destination picture with an offset on both axes after first confirming that the part will fit. The method does nothing if the part won't fit.

The copy process causes selected pixel colors in the destination picture to be replaced by pixel colors from the source picture.

The offset values

The next two parameters named **xOff** and **yOff** in Listing 7 (p. 717) specify the location in the destination picture where the upper-left corner of the cropped source picture is to be located.

The statement in Listing 6 (p. 716) passes the values (82,70) for these two values. This is the location of the upper left corner of the left-most butterfly image in Figure 3 (p. 711) .

Not really cropped For clarity, I will refer to this as a cropped source picture even though the program doesn't actually save a cropped version of the picture as was the case with the **cropAndFlip** method.

The program simply copies a rectangular portion of the source picture into the destination picture.

Upper-left cropping corner

The parameters named **xCoor** and **yCoor** in Listing 7 (p. 717) specify the upper-left corner of the rectangular area of pixels that is to be preserved when the source image is cropped.

Coordinate values of (4,5) are passed for these two values when the method is called in Listing 6 (p. 716)

Same values as Listing 3 (p. 714)

Note that these are the same two values that were passed for this purpose when the `cropAndFlip` method was called in Listing 3 (p. 714) .

Two ways to specify a rectangle

There are two commonly used ways to specify a rectangular area in programming. One way is to specify the coordinates of the upper-left and bottom right corners. This is the approach used in the `cropAndFlip` method in Listing 4 (p. 715) .

The other way is to specify the coordinates of the upper-left corner and then to specify the width and the height. This is the approach used in the `copyPictureWithCrop` method in Listing 7 (p. 717) .

The width and height parameters

The parameters named `width` and `height` in Listing 7 (p. 717) specify the width and height of the rectangular area of pixels that is to be preserved when the source picture is cropped.

If you compare the width and height parameter values passed in Listing 6 (p. 716) with the coordinate values passed in Listing 3 (p. 714) , you will see that the same rectangular area of the butterfly image is being preserved after cropping in both cases.

Confirm that the cropped image will fit

Listing 7 (p. 717) begins by confirming that the cropped rectangular area of the source picture will fit within the destination picture when placed at the specified location. If the conditional clause of the `if` statement returns true, then the code in the body of the statement will be executed. If not, control bypasses the body of the `if` statement and the source picture will not be copied into the destination picture.

Process using nested for loops

As was the case in Listing 4 (p. 715) , Listing 7 (p. 717) declares two working variables named `pixel` and `color` .

The variables named `pixel` and `color` are used along with various parameter values in the pair of nested `for` loops shown in Listing 8 (p. 718) to crop the source picture and to copy the cropped source picture into the destination picture at the specified location.

Listing 8 . Process using nested loops.

```

    for(int col = 0;col < width;col++){
    for(int row = 0;row < height;row++){
        color = source.getPixel(
            col + xCoor,row + yCoor).getColor();
        pixel = dest.getPixel(col+xOff,row+yOff);
        pixel.setColor(color);
    }//end inner loop
    }//end outer loop

    }//end if

    }//end copyPictureWithCrop method

} //end class Prob02Runner

```

Table 3.275

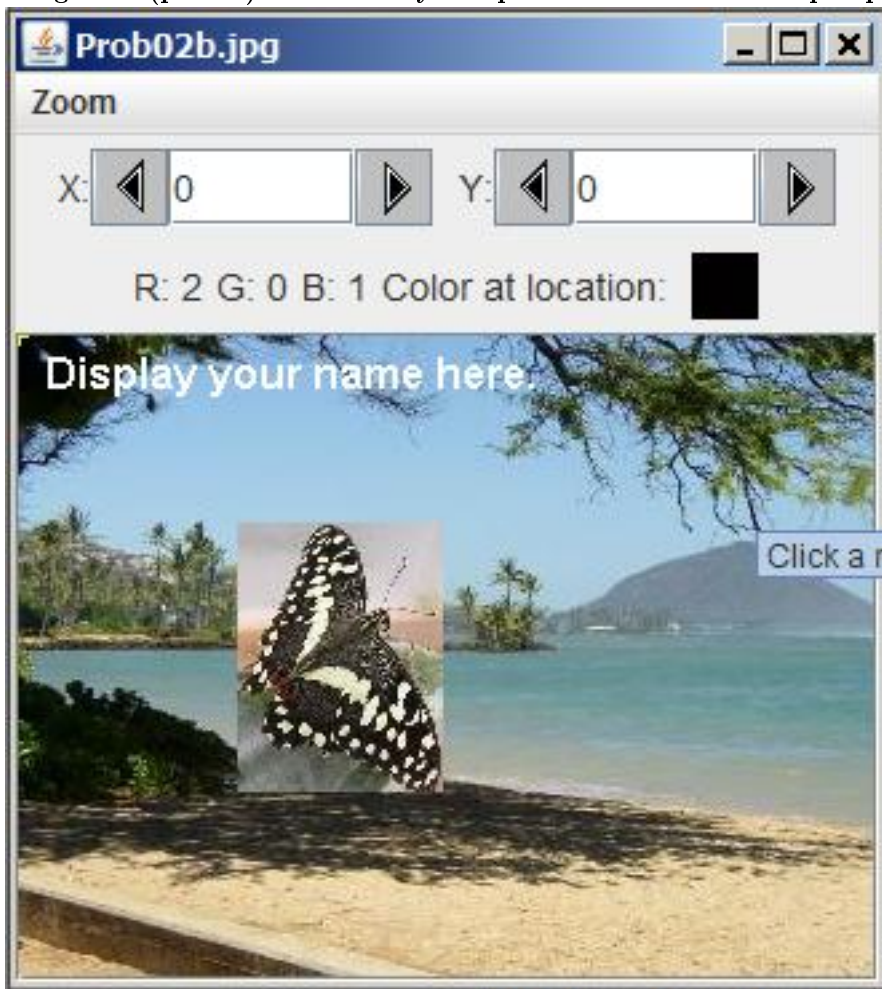

Not as complicated as it looks

Although the arithmetic operations involved in Listing 8 (p. 718) can be daunting, the code in Listing 8 (p. 718) is doing nothing more than replacing selected pixel colors in the destination picture with selected pixel colors from the source picture.

Partially complete version of the output picture.

If you were to display the destination picture before returning control back to the `run` method in Listing 8 (p. 718) , you would see the image shown in Figure 6 (p. 719) .

Figure 6 (p. 719) - Partially complete version of the output picture.

At this point, only one cropped version of the butterfly image has been copied into the beach image.

Return control to the run method

The `copyPictureWithCrop` method terminates in Listing 8 (p. 718) and returns control to the `run` method, picking up where Listing 6 (p. 716) left off.

The remainder of the run method

The remainder of the `run` method is shown in Listing 9 (p. 720) .

Listing 9 . The remainder of the run method.

    return output;

Table 3.276

Call the copyPictureWithCrop method again

Listing 9 (p. 720) begins by calling the **copyPictureWithCrop** method again. This time, however, the picture shown in Figure 5 (p. 716) is passed as the source image with the same picture as before being passed as the destination image.

The offset coordinates

In this case, the offset coordinate values specify the upper-left corner of the right-most butterfly image in Figure 3 (p. 711) .

The cropping parameters

The final four parameters that are passed in Listing 9 (p. 720) specify that the entire source picture is to be copied into the destination picture.

Display the destination picture

When the **copyPictureWithCrop** method returns, Listing 9 (p. 720) calls the **explore** method to display the current state of the destination picture. The result is shown in Figure 3 (p. 711) .

A new array object

Finally, Listing 9 (p. 720) instantiates a new array object, populates it with references to three **Picture** objects, and returns control to the **main** method code in Listing 1 (p. 713) returning a reference to the array object in the process.

The code in Listing 1 (p. 713) saves the reference to the array object in the variable named **pictures** .

Pass Picture object references to println method

Then Listing 1 (p. 713) extracts and passes each of the three **Picture** object references to the **println** method causing the last three lines of text shown in Figure 4 (p. 712) to be displayed on the command-line screen.

The second line of output text (**picA**) describes the raw butterfly image shown in Figure 1 (p. 709) .

The third line of output text for (**picB**) describes the beach scene shown in Figure 2 (p. 710) and Figure 3 (p. 711) .

The last line of output text (**picC**) describes the cropped and flipped version of the butterfly image shown in Figure 5 (p. 716) .

3.3.17.6 Run the program

I encourage you to copy the code from Listing 10 (p. 723) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

This image was also inserted for the purpose of inserting space between the questions and the answers.

3.3.18.6 Answers

3.3.18.6.1 Answer 2

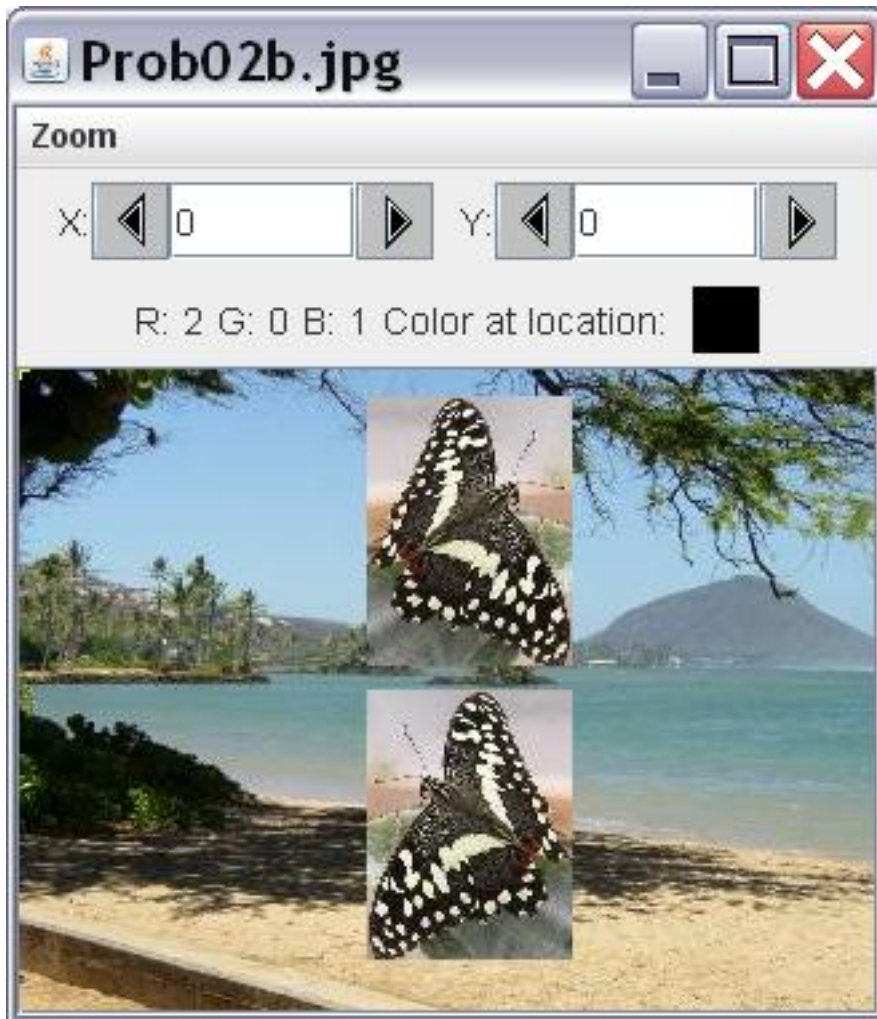

False. The call to the `run` method in Listing 2 (p. 728) returns a reference to an array object whose elements may or may not contain references to objects of the class `Picture` (or some subclass of the class `Picture`). However, since array objects in Java may have a **length** of 0, without seeing the source code for the `run` method, it is impossible to know what is contained in the array object.

Back to Question 2 (p. 728)

3.3.18.6.2 Answer 1

False. The code in Listing 1 (p. 726) combined with the images in Figure 1 (p. 727) and Figure 2 (p. 727) produces the output shown in Figure 4 (p. 730).

3.3.19.3 Preview

In this lesson, you will learn how to write a program to do *green-screen* processing to superimpose a source image onto a destination image while making the green background of the source image appear to be transparent.

Program specifications

Write a program named **Prob03** that uses the class definition shown in Listing 1 (p. 739) and Ericson's media library along with the image files in the following list to produce the five graphic output images shown in Figure 1 (p. 733) through Figure 5 (p. 737) .

- Prob03a.bmp
- Prob03b.bmp
- Prob03c.bmp
- Prob03d.jpg

Figure 2 (p. 734) - Input image file Prob03b.bmp.

Figure 3 (p. 735) - Input image file Prob03c.bmp.

Figure 4 (p. 736) - Input image file Prob03d.jpg.

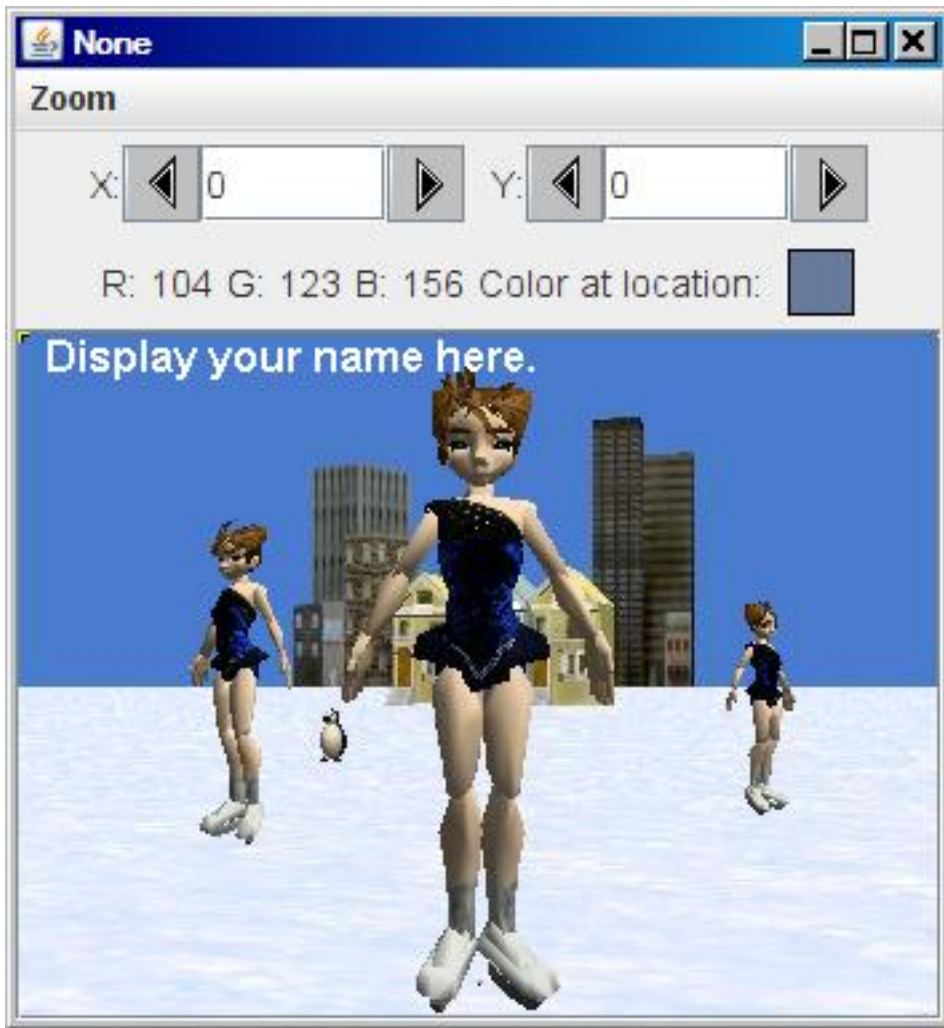

Figure 5 (p. 737) - Output picture.

New classes

You may define new classes as necessary to cause your program to behave as required, but you may not modify the class definition for the class named **Prob03** given in Listing 1 (p. 739) .

Required output text

In addition to the output images mentioned above, your program must display your name and one other line of text on the command-line screen as shown in Figure 6 (p. 738) .

Figure 6 . Required output text.

```

Display your name here.
Picture, filename None height 256 width 344

```

Table 3.280

3.3.19.4 General background information

This program receives three views of an ice skater in **bmp** files with a pure green background along with a **jpg** file containing a snow scene.

All four files show the Alice ³¹³ runtime panel with the words **World Running...** and several associated buttons. (See Figure 1 (p. 733) .)

Program behavior

The program performs the following actions:

- Crops the snow scene to remove the Alice runtime panel.
- Crops the three views of the skater to remove the Alice runtime panel along with excess blank green background.
- Scales two of the views of the skater to smaller sizes.
- Does green-screen processing to place the three views of the skater at different locations in the snow scene.
- Uses position along with size to create an optical illusion of a 3D scene of three ice skaters and a penguin standing at different locations on a frozen lake (see Figure 5 (p. 737)) .

Programming skills required

In order to write this program, the student must be able to, as a minimum, write a green-screen processing method.

3.3.19.5 Discussion and sample code

Will discuss in fragments

I will discuss this program in fragments. A complete listing of the program is provided in Listing 6 (p. 746) near the end of the lesson.

The driver class named Prob03

The driver class containing the **main** method is shown in Listing 1 (p. 739) .

Listing 1 . The driver class named Prob03.

```
import java.awt.Color;

public class Prob03{
    public static void main(String[] args){
        Prob03Runner obj = new Prob03Runner();
        obj.run();
    }//end main
} //end class Prob03
```

Table 3.281

The **main** method in Listing 1 (p. 739) instantiates a new object of the class named **Prob03Runner** and calls the method named **run** that belongs to that object.

When the **run** method returns, the program terminates.

Beginning of the class named Prob03Runner

The beginning of the class named **Prob03Runner** , and its constructor, is shown in Listing 2 (p. 740)

³¹³<http://www.alice.org/>

Listing 2 . Beginning of the class named Prob03Runner.

```

class Prob03Runner{

public Prob03Runner(){//constructor
    System.out.println("Display your name here.");
} //end constructor

```

Table 3.282

The constructor simply displays the student's name on the command line screen producing the first line of text shown in Figure 6 (p. 738) .

Beginning of the run method

The beginning of the **run** method that is called in Listing 1 (p. 739) is shown in Listing 3 (p. 740) .

Listing 3 . Beginning of the run method.

```

public void run(){

//A view facing the front of the skater.
Picture front = new Picture("Prob03a.bmp");
front.explore();
front = crop(front,123,59,110,256);

//A view showing the right side of the skater.
Picture right = new Picture("Prob03b.bmp");
right.explore();
right = crop(right,123,59,110,256);

//A view showing the left side of the skater.
Picture left = new Picture("Prob03c.bmp");
left.explore();
left = crop(left,123,59,110,256);

//This will be the background for the new picture.
Picture snowScene = new Picture("Prob03d.jpg");
snowScene.explore();
snowScene = crop(snowScene,6,59,344,256);

```

Table 3.283

The code in Listing 3 (p. 740) instantiates, displays, and crops the four input images.

All four images must be cropped to remove the Alice runtime window. In addition, the three skater images are also cropped to remove excess blank green background material.

Image formats: bmp versus jpg

Note that the three views of the skater are extracted from **bmp** image files instead of **jpg** image files. This is necessary in order to preserve the pure green background color. Storing the images as **jpg** files

would corrupt the background color in the low order bits making it more difficult to achieve the green-screen processing required by this program.

The method named `crop`

Listing 3 (p. 740) calls the `crop` method four times in succession, once for each of the four `Picture` objects instantiated from the image files.

I explained image cropping in an earlier module. The `crop` method used in this program is very similar to the methods that I explained in the earlier module, so I won't explain it again in this module. You can view the `crop` method in detail in Listing 6 (p. 746) near the end of the module.

Five incoming parameters

The `crop` method requires five incoming parameters. The first parameter is a reference to the `Picture` object that is to be cropped. The remaining four integer parameters specify the rectangular area that is to be preserved after the picture is cropped.

The rectangular area to be preserved

The first two integers specify the column and row coordinates for the upper-left corner of the rectangular area that is to be preserved. The last two integers specify the width and the height of the rectangle that is to be preserved.

Note that in all four cases, the height of the rectangular area that is to be preserved is 256 pixels. This will be important later on with respect to scaling two of the images.

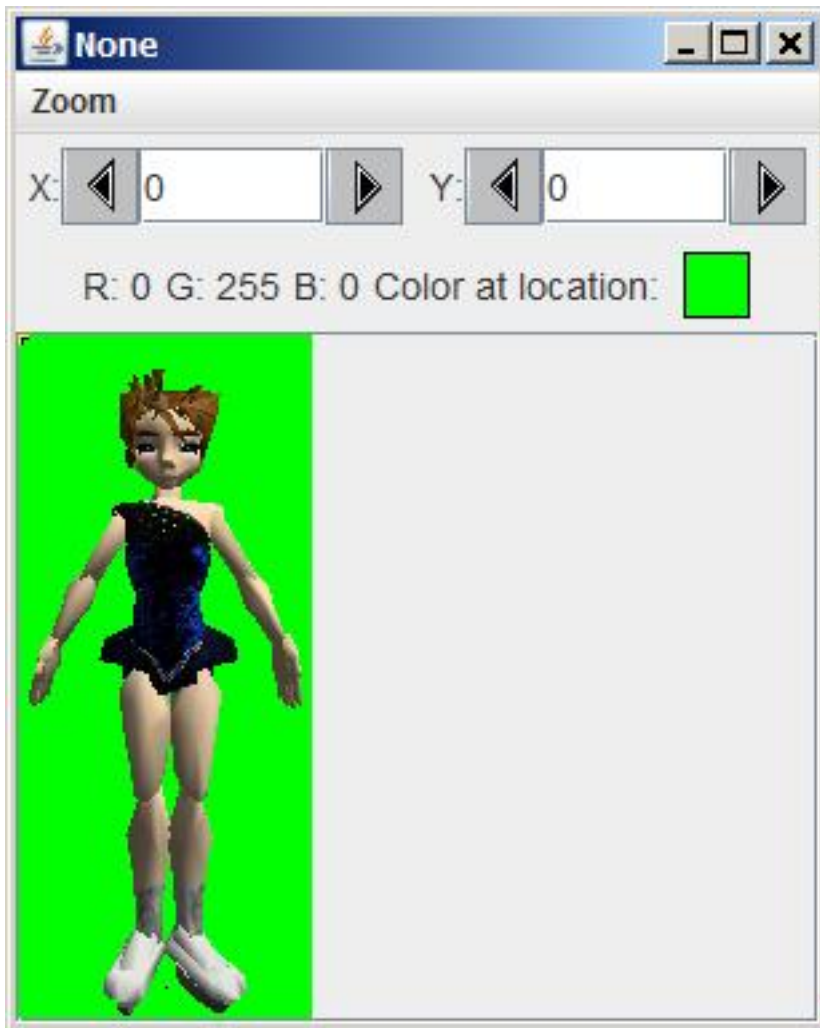

Returns a reference to a cropped picture

The `crop` method returns a reference to a `Picture` object that is a cropped version of the picture whose reference is passed to the method. In each case, the code in Listing 3 (p. 740) replaces the reference to the original `Picture` object with the reference to the cropped `Picture` object.

Front view of the skater after cropping

If you were to display the `Picture` object referred to by the variable `front` after cropping, you would see the image shown in Figure 7 (p. 741).

Figure 7 (p. 741) - Front view of the skater after cropping.

Transparent pixels

This is the image that appears as the center ice skater in Figure 5 (p. 737) after green-screen processing. Note that all of the green pixels in Figure 7 (p. 741) appear to be transparent in Figure 5 (p. 737) .

Remainder of the run method

Continuing with the `run` method, Listing 4 (p. 743) calls the method named `greenScreenDraw` three times in succession to draw the three skater images at specific locations on the snow scene with green-screen processing.

Listing 4 . Remainder of the run method.

```

        //Draw the front view of the skater on the snowScene
        // at full size.
        greenScreenDraw(front,snowScene,117,0);

        //Draw the left side view of the skater on the
        // snowScene at half size.
        left = left.getPictureWithHeight(256/2);
        greenScreenDraw(left,snowScene,55,64);

        //Draw the right side view of the skater on the
        // snowScene at one-third size.
        right = right.getPictureWithHeight(256/3);
        greenScreenDraw(right,snowScene,260,96);

        //Display students name on the final output and
        // display it.
        snowScene.addMessage("Display your name here.",10,15);
        snowScene.explore();
        System.out.println(snowScene);
    }//end run method

```

Table 3.284**Two skater images are scaled**

In two cases in Listing 4 (p. 743) , the method named **getPictureWithHeight** is called before calling the **greenScreenDraw** method. The **getPictureWithHeight** method is used to scale two of the images to a smaller size as shown in Figure 5 (p. 737) .

The getPictureWithHeight method

The **getPictureWithHeight** method is defined in Ericson's **SimplePicture** class and inherited into Ericson's **Picture** class.

The method requires a single integer input parameter, which specifies the height in pixels of a scaled output version of the picture object on which the method is called.

According to the documentation, the method can be used to create a new picture with the specified height. The aspect ratio of the width and height will stay the same.

Original height is 256 pixels

Referring back to the parameters that were passed to the **crop** method in Listing 3 (p. 740) , you can see the height of all three cropped images is 256 pixels.

Scale by 1/2 and 1/3

Referring to the two calls to the **getPictureWithHeight** method in Listing 4 (p. 743) , you can see that one of the cropped images was replaced with an image having a height of $256/2$ or 128 pixels. The other cropped image was replaced with an image having a height of $256/3$ or 85 pixels. You can see the effect of this scaling in Figure 5 (p. 737) .

The height of one of the images was not changed, which you can also see in Figure 5 (p. 737) .

Put the run method on hold

I will put the explanation of the **run** method on temporary hold at this point and explain the method named **greenScreenDraw** , which is shown in Listing 5 (p. 744) .

Behavior of the greenScreenDraw method

The **greenScreenDraw** method requires four incoming parameters:

- A reference to a source image.
- A reference to a destination image
- The horizontal coordinate on the destination image where the upper-left corner of the source image will be drawn.
- The vertical coordinate on the destination image where the upper-left corner of the source image will be drawn.

Pure green pixels are required for transparency

The method draws the source image onto the destination image at the specification location. However, pixels having a pure green color are not drawn on the destination image. The effect is to make it appear that those portions of the source image with pure green pixels become totally transparent allowing the pixels belonging to the destination image to show through.

jpg image files are not satisfactory for this program

Picture objects created from jpg image files typically won't have a pure green background even if they had a pure green background before being compressed into the jpg format file. However, the bmp file format does not corrupt the pixel colors. Therefore, bmp images work well for this type of processing.

The greenScreenDraw method

The **greenScreenDraw** method is shown in its entirety in Listing 5 (p. 744) .

Listing 5 . The greenScreenDraw method.

```
private void greenScreenDraw(
    Picture source,
    Picture dest,
    //Place the upper-left corner
    // of the source image at the
    // following location in the
    // destination image.
    int destX,
    int destY){
int width = source.getWidth();
int height = source.getHeight();
Pixel pixel = null;
Color color = null;

for(int row = 0;row < height;row++){
    for(int col = 0;col < width;col++){
        color = source.getPixel(col,row).getColor();
        if(!(color.equals(Color.GREEN))){
            pixel = dest.getPixel(destX + col,destY + row);
            pixel.setColor(color);
        }//end if
    }//end inner loop
} //end outer loop

} //end greenScreenDraw
```

Table 3.285

Very similar to earlier methods

This method is very similar to other methods that I have explained in earlier modules that use nested **for** loops to draw one image onto another image.

The one new thing...

The only thing that is really new in Listing 5 (p. 744) is the **if** statement that tests the color of source image pixels for a value of exactly **Color.GREEN** . If the color of the source pixel does not match that color exactly, it is drawn on the destination image replacing the pixel color previously at that location on the destination image.

If the source pixel color does exactly match that color, it is not drawn on the destination image thereby leaving the color of the corresponding destination pixel unchanged.

Listing 5 (p. 744) signals the end of the **greenScreenDraw** method.

The weather forecast on television

This is roughly how the TV stations superimpose a human weather forecaster onto a giant animated weather map. The forecaster is photographed with a video camera standing in front of a green or blue screen. At the same time, an animated video of the weather map is also created.

Then each video frame of the forecaster is superimposed onto a video frame of the weather map. The green or blue pixels in the forecaster frame are not copied onto the weather map frame. This allows the weather map pixels to show with the exception of those that are replaced by the pixels that comprise the human forecaster. (*The forecaster must be careful to avoid wearing clothing that matches the color of the green or blue screen.*)

Returning to the run method

When the third call to the **greenScreenDraw** method returns in Listing 4 (p. 743) , the **run** method:

- Adds the student's name to the snow scene picture.
- Displays the snow scene picture (see Figure 5 (p. 737)).
- Displays information about the snow scene picture on the command line screen.

The end of the program

Then the **run** method in Listing 4 (p. 743) returns control to the **main** method in Listing 1 (p. 739) causing the program to terminate.

3.3.19.6 Run the program

I encourage you to copy the code from Listing 6 (p. 746) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

3.3.21.3 Preview

In this module, you will learn how to darken, brighten, and tint the colors in a **Picture** object.

Program specifications

Write a program named **Prob04** that uses the class definition shown in Listing 1 (p. 765) and Ericson's media library along with the image files in the following list to produce the four graphic output images shown in Figure 1 (p. 760) through Figure 4 (p. 763) .

- Prob04a.bmp
- Prob04b.bmp
- Prob04c.jpg

Figure 1 (p. 760) - Input file Prob04a.bmp.

Figure 2 (p. 761) - Input file Prob04b.bmp.

Figure 3 (p. 762) - Input file Prob04c.jpg.

Figure 4 (p. 763) - Required output image.

New classes

You may define new classes as necessary to cause your program to behave as required, but you may not modify the class definition for the class named **Prob04** shown in Listing 1 (p. 765) .

Required text output

In addition to the four output images mentioned above, your program must display your name and the other line of text shown in Figure 5 (p. 764) on the command-line screen.

Figure 5 - Required text output.

    Display your name here.
    Picture, filename None height 293 width 392

```

Table 3.288

3.3.21.4 General background information

This program uses a black ellipse on a green background (see Figure 2 (p. 761)) as a pattern to cause the pixels in a snow scene (see Figure 3 (p. 762)) at the location of the ellipse to be given a red tint and causes all other pixels in the snow scene to be darkened (see Figure 4 (p. 763)) .

The program also causes a red skater in a green background (see Figure 1 (p. 760)) to be given a red tint and then drawn on the snow scene at the location of the red-tinted ellipse. The effect is that of a spotlight with a red tint shining on the skater (see Figure 4 (p. 763)) .

3.3.21.5 Discussion and sample code

Will discuss in fragments

I will discuss this program in fragments. A complete listing of the program is provided in Listing 10 (p. 776) near the end of the module.

The driver class named Prob04

The driver class containing the **main** method is shown in Listing 1 (p. 765) .

Listing 1 - The driver class named Prob04.

```

import java.awt.Color;

public class Prob04{
    public static void main(String[] args){
        Prob04Runner obj = new Prob04Runner();
        obj.run();
    }//end main
} //end class Prob04

```

Table 3.289

As has been the case in several earlier modules, the code in the **main** method instantiates an object of the class named **Prob04Runner** and calls the **run** method on that object.

When the **run** method returns, the **main** method terminates causing the program to terminate.

Beginning of the class named Prob04Runner

The class named **Prob04Runner** begins in Listing 2 (p. 766) .

Listing 2 - Beginning of the class named Prob04Runner.

```

class Prob04Runner{

public Prob04Runner(){//constructor
    System.out.println("Display your name here.");
} //end constructor

```

Table 3.290

Listing 2 (p. 766) shows the constructor for the class, which simply displays the student's name on the command line screen as shown in Figure 5 (p. 764) .

Beginning of the run method

The beginning of the **run** method, which is called in Listing 1 (p. 765) , is shown in Listing 3 (p. 766) .

Listing 3 - Beginning of the run method.

```

public void run(){

Picture skater = new Picture("Prob04a.bmp");
skater.explore();
skater = crop(skater,6,59,392,293);

Picture hole = new Picture("Prob04b.bmp");
hole.explore();
hole = crop(hole,6,59,392,293);

Picture snowScene = new Picture("Prob04c.jpg");
snowScene.explore();
snowScene = crop(snowScene,6,59,392,293);

```

Table 3.291**Instantiate and display three Picture objects**

The code in Listing 3 (p. 766) instantiates **Picture** objects from the three image files and displays those pictures in Figure 1 (p. 760) , Figure 2 (p. 761) , and Figure 3 (p. 762) .

Crop the pictures

Note that the images in those three pictures contain the **Alice**³³⁰ runtime window controls as a banner that reads **World Running...** and a line of buttons.

The method named crop

Listing 3 (p. 766) calls a method named **crop** on all three **Picture** objects to eliminate the **Alice** runtime controls. Note that the same rectangular area is preserved for all three images. Thus, all three images are the same size after cropping.

The cropped snow scene image

³³⁰<http://www.alice.org/>

If you were to display the picture whose reference is stored in the variable named `snowScene` after the `crop` method returns, you would see the image shown in Figure 6 (p. 767) with the `Alice` runtime controls no longer visible.

Figure 6 (p. 767) - Cropped version of the snow scene image.

The crop method

The method named `crop` that was used to crop the three pictures is essentially the same as the cropping methods that I explained in earlier modules. Therefore, I won't repeat that explanation here. You can view the `crop` method in its entirety in Listing 10 (p. 776) near the end of the module.

Darken the background of the snow scene

Listing 4 (p. 768) calls the method named `darkenBackground` to make all of the pixels darker in the snow scene except for those in the location of the ellipse as shown in Figure 4 (p. 763) . The pixels at the location of the ellipse are given a red tint.

Listing 4 - Darken the background of the snow scene.

```
darkenBackground(hole, snowScene);
```

Table 3.292**Put the run method on temporary hold**

I will put the explanation of the `run` method on hold at this point and explain the method named `darkenBackground` .

The method named `darkenBackground`

The method named `darkenBackground` receives references to two `Picture` objects as parameters. It uses the first picture as a *pattern* from which it determines which pixels in the second picture (*destination*) should be darkened.

The *pattern* and *destination* images

In this case, a cropped version of the image of the black ellipse shown in Figure 2 (p. 761) is the pattern. The cropped image of the snow scene shown in Figure 6 (p. 767) is the destination image whose pixels will be darkened.

Assumptions

The `darkenBackground` method assumes that the pattern image has a pure green background as shown in Figure 2 (p. 761) . It also assumes that the pattern and the destination have the same dimensions.

Behavior of the method

The `darkenBackground` method darkens every pixel in the destination that is at the location of a green pixel in the pattern.

The method applies a red tint to every pixel in the destination that is at the location of a non-green pixel in the pattern

Beginning of the `darkenBackground` method

The `darkenBackground` method begins in Listing 5 (p. 768) .

Listing 5 - Beginning of the `darkenBackground` method.

```
private void darkenBackground(Picture pattern,
                             Picture dest){

    Pixel[] patternPixels = pattern.getPixels();
    Pixel[] destPixels = dest.getPixels();
    Color color = null;
    int red = 0;
    int green = 0;
    int blue = 0;
```

Table 3.293**Get two arrays of pixel data**

The `darkenBackground` method begins by calling the `getPixels` method on each of the picture objects to create a pair of array objects containing pixel data.

You learned how to use the `getPixels` method in an earlier module. Recall that this approach is useful when you don't need to be concerned about the locations of the pixels in an x-y coordinate system.

Arrays have the same length

Because the two pictures have the same dimensions, the two arrays have the same length.

A given array index specifies pixel data from the same location in both pictures.

Beginning of the processing loop

The method uses a **for** loop to traverse the two arrays of pixel data in parallel, using information from the *pattern* picture to make the color changes to the *destination* picture described above. The **for** loop begins in Listing 6 (p. 769) .

Listing 6 - Beginning of the processing loop.

```

    for(int cnt = 0;cnt < patternPixels.length;cnt++){
    color = patternPixels[cnt].getColor();
    if(color.equals(Color.GREEN)){
        //Darken corresponding pixel in the destination.
        color = destPixels[cnt].getColor();
        destPixels[cnt].setColor(color.darker());
    }
}

```

Table 3.294**Behavior of the processing loop**

The loop begins by getting the color value of the next pixel in the pattern array. If the color of the pattern pixel is green, the code in Listing 6 (p. 769) :

- Gets the color from the corresponding pixel in the destination array.
- Calls the method named **darker** , which is a method of the **Color** class in the standard Sun library, to produce a darker version of the pixel color.
- Replaces the pixel color in the destination array with the darker version of the color.

Compare images to see the results

If you compare Figure 4 (p. 763) with Figure 3 (p. 762) , you will see that (*ignoring the skater and the ellipse*) , all of the pixels in Figure 4 (p. 763) are darker versions of the colors in Figure 3 (p. 762) .

The brighter method

The **Color** class also provides a method named **brighter** which has the opposite effect. In particular, it can be used to brighten the color of a pixel.

These two methods are very useful for making a pixel darker or brighter without having to know anything about the actual color of the pixel.

The else clause in the processing loop

If the color of the pattern pixel (*tested in Listing 6 (p. 769)*) is not green, the code in the **else** clause in Listing 7 (p. 770) is executed.

Listing 7 - The else clause in the processing loop.

continued on next page

```

        }else{
//Apply a red tint to the corresponding pixel in
// the destination.
color = destPixels[cnt].getColor();
red = color.getRed();
if(red*1.25 < 255){
    red = (int)(red * 1.25);
}else{
    red = 255;
} //end else
green = (int)(color.getGreen() * 0.8);
blue = (int)(color.getBlue() * 0.8);
destPixels[cnt].setColor(new Color(red,green,blue));
} //end else
} //end for loop

} //end darkenBackground

```

Table 3.295

The snow scene and the ellipse only...

At this point, only the images from Figure 2 (p. 761) (*the ellipse*) and Figure 3 (p. 762) (*the snow scene*) are being processed. The image of the skater in Figure 1 (p. 760) hasn't entered the picture yet.

Application of the ellipse pattern

The code in Listing 7 (p. 770) is executed only if the pixel from the destination picture is at a location that matches one of the non-green (*black*) pixels in the ellipse in Figure 2 (p. 761).

(*The fact that the pixel is black is of no consequence. The only thing that matters is that it is not green.*)

The objective of the else clause

The objective is to modify the pixel color in the destination picture at this location to give it a red tint as shown in Figure 4 (p. 763).

Get, save, and modify the red color value

Listing 7 (p. 770) begins by getting the color of the pixel from the current location in the destination picture. It extracts and saves the red color value of the pixel. Then, depending on the current value of the red color value, it either:

- Multiplies the red color value by a factor of 1.25, or
- Sets the red color value to the maximum allowable value of 255.

Decrease the color values for blue and green

Following this, it gets the green and blue color values and multiplies each of them by 0.8.

Replace the old pixel color with the new color

Finally, it replaces the pixel color with a new color using the modified values of red, green, and blue.

The texture is preserved

As you can see in Listing 4 (p. 768), this process causes the pixels in locations that match the ellipse to take on a red tint, but the texture of the image is not destroyed as it would be if the pixels had simply been replaced by pixels that all have the same color of pink.

The end of the darkenBackground method

Listing 7 (p. 770) signals the end of the processing loop and the end of the **darkenBackground** method.

Apply a red tint to the skater

Returning to where we left off in the `run` method in Listing 4 (p. 768) , the code in Listing 8 (p. 771) calls a method named `redTint` , passing a reference to the picture that contains a cropped image of the skater. The method applies a red tint to the skater.

Listing 8 - Apply a red tint to the skater.
--

<pre>redTint(skater);</pre>

Table 3.296

The `redTint` method assumes that the image being processed has a pure green background like that shown in Figure 1 (p. 760) . The method applies an algorithm very similar to that shown in Listing 7 (p. 770) to apply a red tint to every pixel that is not pure green.

Because of the similarity of the code in the `redTint` method and the code in Listing 7 (p. 770) , a detailed explanation of the `redTint` method should not be required. You can view the method in its entirety in Listing 10 (p. 776) near the end of the module.

The skater with the red tint applied

If you were to display the picture referred to by `skater` immediately after the `redTint` method returns in Listing 8 (p. 771) , you would see the image shown in Figure 7 (p. 771) .

Figure 7 (p. 771) - The skater with a red tint applied.

Compare Figure 7 (p. 771) with Figure 1 (p. 760)

You can see the effect of applying the red tint process to the skater by comparing Figure 7 (p. 771) with Figure 1 (p. 760) . Note that the process does not change the color of the green pixels.

The remainder of the run method

Continuing with the `run` method, Listing 9 (p. 773) calls a method named `greenScreenDraw` to draw the cropped, red-tinted skater on the snow scene as shown in Figure 4 (p. 763) .

Listing 9 - The remainder of the run method.

continued on next page

```

        //Draw the skater on the snowScene.
greenScreenDraw(skater,snowScene,0,0);

//Display students name on the final output and
// display it.
snowScene.addMessage("Display your name here.",10,15);

snowScene.explore();
System.out.println(snowScene);

} //end run method

```

Table 3.297

Behavior of the method

The **greenScreenDraw** method copies all non-green pixels from a source image to a destination image at a specified location. This method is very similar to methods that I have explained in earlier modules. Therefore, an explanation of the method in this module should not be needed.

You can view the **greenScreenDraw** method in its entirety in Listing 10 (p. 776) near the end of the module.

Add text and display the final output image

When the **greenScreenDraw** method returns, Listing 9 (p. 773) calls the **addMessage** method to display the student's name on the snow scene and then calls the **explore** method to produce the output image shown in Figure 4 (p. 763) . None of that should be new to you at this point.

Display text and return

Finally, Listing 9 (p. 773) displays some information on the command line screen as shown in Figure 5 (p. 764) and returns control to the **main** method in Listing 1 (p. 765) .

Terminate the program

Having nothing more to do, the **main** method terminates, causing the program to terminate and return control to the operating system.

3.3.21.6 Run the program

I encourage you to copy the code from Listing 10 (p. 776) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

3.3.23.3 Preview

In this module, you will learn about :

- Interface definitions
- Implementing an interface in a class definition
- Defining interface methods in a class definition
- Storing references to new objects in elements of an array of type **Object**
- Casting elements to an interface type in order to call interface methods
- Parameterized constructors
- Overridden **toString** method

Program specifications

Write a program named **Prob05** that uses the class definition shown in Listing 1 (p. 789) to produce the output shown in Figure 1 (p. 788) on the command line screen.

Figure 1 . Command line output for Prob05.

```

Prob05
Put your first name here
Put your last name here
-18 -17 -16
-17 -17 -17
-12 -12 -12

```

Table 3.300

No graphic output images required

There are no graphic output images required by this program. Therefore, it can be compiled and executed without a requirement to have Ericson's media library on the classpath.

Required text output

The output, which appears on the command line screen, consists of the six lines of text shown in Figure 1 (p. 788) .

Because the program generates random data for testing, the actual values will differ from one run to the next. However, in all cases:

- The values in the first row of numbers will be a sequence of consecutive integers in increasing algebraic order from left to right.
- All three values in the second row of numbers will match the value of the center number in the first row of numbers.
- All three values in the third row of numbers will be algebraically five greater than the values in the second row of numbers.

New classes

You may define new classes as necessary to cause your program to behave as required, but you may not modify the class definition for the class named **Prob05** shown in Listing 1 (p. 789) .

3.3.23.4 General background information

Among other things, this program illustrates:

- Interface definitions
- Implementing an interface in a class definition
- Defining interface methods in a class definition
- Storing references to new objects in elements of an array of type **Object**
- Casting elements to an interface type in order to call interface methods
- Parameterized constructors
- Overridden **toString** method

3.3.23.5 Discussion and sample code

Will explain in fragments

I will explain this program in fragments. A complete listing of the program is provided in Listing 13 (p. 801) near the end of the module.

Beginning of driver class for Prob05

The driver class for **Prob05** begins in Listing 1 (p. 789) .

Listing 1 . Beginning of driver class for Prob05.

```
import java.util.*;

class Prob05{
    public static void main(String[] args){

        Random generator = new Random(new Date().getTime());
        int randomData = (byte)generator.nextInt();

        Object[] var1 = new Object[2];

        var1[0] = new Prob05MyClassA(randomData);
        var1[1] = new Prob05MyClassB(randomData);
    }
}
```

Table 3.301

Behavior of the code in Listing 1 (p. 789)

Listing 1 (p. 789) does the following:

- Gets and saves a random value of type `int` .
- Instantiates a new two-element array object of type `Object` . (A reference to any object of any class or interface type can be stored in an array element of type `Object` .)
- Populates the array object with references to objects of the classes:
 - `Prob05MyClassA`
 - `Prob05MyClassB`

The same random value is passed to the constructor for both objects when they are instantiated.

Put the driver class on temporary hold

At this point, I am going to put the driver class named `Prob05` on temporary hold and explain the class named `Prob05MyClassA` .

The interface named `Prob05X`

Having glanced ahead, I know that the class named `Prob05MyClassA` implements the interface named `Prob05X` so I will explain that interface first.

The interface named `Prob05X` is shown in its entirety in Listing 2 (p. 790) .

Listing 2 . The interface named `Prob05X`.

```
interface Prob05X{
    public int getModifiedData();
    public int getData();
} //end interface
```

Table 3.302

An interface definition

An interface definition can contain only two kinds of members:

- Constants
- Method declarations

By now, you should have studied interfaces in my online tutorials. Therefore, this explanation will be very brief.

Method declarations

Listing 2 (p. 790) contains two method declarations.

A method declaration does not have a body. Its purpose is to establish the programming interface for that method in any class that implements the interface (*return type, name, arguments, etc.*) .

A method declaration provides no information about the behavior of the method.

A method declaration in an interface is implicitly abstract.

A concrete definition is required

Any class that implements an interface:

- Must provide a **concrete** version of every method that is declared in the interface, or
- The class must be declared **abstract** . (*In this case, abstract essentially means incomplete.*)

The class named `Prob05MyClassA`

The class named `Prob05MyClassA` , which implements the interface named `Prob05X` , must provide concrete versions of the methods named:

- `public int getModifiedData()`

- `public int getData()`

Beginning of the class named `Prob05MyClassA`

The class named `Prob05MyClassA` begins in Listing 3 (p. 791) .

Listing 3 . Beginning of the class named `Prob05MyClassA`.

```
class Prob05MyClassA implements Prob05X{
private int data;//instance variable

Prob05MyClassA(int inData){//constructor
    System.out.println("Prob05");
    System.out.println("Put your first name here");
    data = inData;
} //end constructor
```

Table 3.303

This class implements the interface named `Prob05X` .

A private instance variable

Listing 3 (p. 791) begins by declaring a private instance variable of type `int` named `data` . As a private instance variable, it is accessible by any method or constructor defined within the class but is not accessible to methods from outside the class.

The constructor

The constructor for the class is shown in its entirety in Listing 3 (p. 791) .

The constructor begins by displaying the problem number and the student's first name on the command line screen.

Then it assigns the value of the incoming parameter named `inData` to the variable named `data` . This makes that value available to the methods that are defined within the class.

The method named `getModifiedData`

We learned earlier ³⁴⁵ that the class named `Prob05MyClassA`

- must provide a concrete definition of the method named `getModifiedData` ,
- because that method is declared in the interface named `Prob05X` ,
- which is implemented by the class.

With the exception of some very subtle differences (*that are beyond the scope of this course*) , that concrete definition must match the signature of the declared method.

Code for the method named `getModifiedData`

The method named `getModifiedData` is shown in its entirety in Listing 4 (p. 793) .

When this method is called, it

- subtracts a value of 1 from the value stored in the instance variable named `data` , and
- returns that modified value.

³⁴⁵<http://cnx.org/content/m44214/latest/Java3020old.htm#concrete>

Listing 4 . The method named `getModifiedData`.

```

    public int getModifiedData(){
    return data - 1;
    }//end getModifiedData()

```

Table 3.304**The method named `getData`**

We also learned earlier that the class named **Prob05MyClassA**

- must provide a concrete definition of the method named **`getData`**,
- which is also declared in the interface named **Prob05X** .

Code for the method named `getData`

The method named **`getData`** is shown in its entirety in Listing 5 (p. 793) .

This method returns a copy of the value stored in the variable named **`data`** .

Listing 5 . The method named `getData`.

```

    public int getData(){
    return data;
    }//end getData()

```

Table 3.305**A round trip**

When the code in Listing 1 (p. 789) instantiates an object of the **Prob05MyClassA** class, it passes a random value as a parameter to the constructor.

The constructor shown in Listing 3 (p. 791) stores that random value in the instance variable named **`data`** .

When the method named **`getModifiedData`** is called, it returns a value that is the original random value less 1.

When the method named **`getData`** is called, it returns a copy of the original random value.

The `toString` method

The class named **Prob05MyClassA** extends the class named **Object** by default. It inherits a method named **`toString`** from the class named **Object** . The inherited method has very specific behavior.

Overridden `toString` method

The code in Listing 6 (p. 794) overrides the inherited method to provide a different behavior when the method is executed in conjunction with an object of the **Prob05MyClassA** class.

The new behavior is to construct and return a string version of the value obtained by adding 5 to the value stored in **`data`** , which is the original random value.

Listing 6 . Overridden toString method.

```

    public String toString(){
    return "" + (data + 5);
    }//end toString()

} //end class Prob05MyClassA

```

Table 3.306**The end of the class named Prob05MyClassA**

Listing 6 (p. 794) also signals the end of the class definition for the class named **Prob05MyClassA** .

The class named Prob05MyClassB

Referring back to the code in the driver class in Listing 1 (p. 789) , we see that the driver also instantiates an object of the class named **Prob05MyClassB** , passing the same random value to the constructor for the class.

The reference to the object is stored in the second element of the array object of type **Object** referred to by the reference variable named **var1** .

Beginning of the class named Prob05MyClassB

The beginning of the class named **Prob05MyClassB** is shown in Listing 7 (p. 794) .

Listing 7 . Beginning of the class named Prob05MyClassB.

```

class Prob05MyClassB implements Prob05X{
private int data;

Prob05MyClassB(int inData){
    System.out.println("Put your last name here");
    data = inData;
} //end constructor

```

Table 3.307**Implements Prob05X**

The first thing we notice is that this class also implements the interface named **Prob05X** . This requires that the class provide concrete definitions of the two methods declared in that interface.

Save the incoming parameter value

The constructor for the **Prob05MyClassB** class, which is shown in Listing 7 (p. 794) , saves the incoming parameter value in a private instance variable named **data** .

Unrelated to the variable named data from before

It is important to note that this variable named **data** is completely unrelated to the private instance variable named **data** that is declared in Listing 3 (p. 791) , even though they are the same type and they have the same name.

They belong to two different objects. Objects do not share instance variables.

The two objects are related

However, even though the two objects instantiated in Listing 1 (p. 789) are instantiated from different classes, they are related in the sense that they have two ancestors in common. They both extend the class

named **Object** by default and they both explicitly implement the interface named **Prob05X** . That means that they can both be treated as either type **Object** or type **Prob05X** .

Related through the interface by design

Because all classes are direct or indirect subclasses of the class named **Object** , all objects instantiated for any class are related at the **Object** level. However, the objects in this program are related through the **Prob05X** interface only because I designed the program that way.

The method named `getModifiedData`

The method named `getModifiedData` is shown in Listing 8 (p. 795) .

Listing 8 . The method named `getModifiedData`.

```
public int getModifiedData(){
    return data + 1;
} //end getModifiedData()
```

Table 3.308

Same behavior is not required

A comparison of Listing 8 (p. 795) with Listing 4 (p. 793) exposes a very important aspect of interface implementation.

If two different classes implement the same interface, they each must provide concrete definitions of all the method declared in the interface. When providing such concrete definitions, both classes must match the method signatures of the declared methods.

However, the behavior of a method as defined in one class is not required to be the same as the behavior of the method having the same signature in the other class.

The behavior is different

For example, the code in Listing 4 (p. 793) *subtracts 1* from the value of **data** and returns that modified value.

The code in Listing 8 (p. 795) *adds 1* to the value of **data** and returns that modified value.

Therefore, the behavior of the method named `getModifiedData` in an object instantiated from the class named **Prob05MyClassB** is completely different from the behavior of the method having the same signature in an object of the class named **Prob05MyClassA** .

The `getData` and `toString` methods

Listing 9 (p. 795) shows the `getData` and `toString` methods as defined in the class named **Prob05MyClassB** .

Listing 9 . The `getData` and `toString` methods.

```
public int getData(){
    return data;
} //end getData()

public String toString(){
    return "" + (data + 5);
} //end toString()

} //end class Prob05MyClassB
```

Table 3.309

The behavior is the same

If you compare Listing 9 (p. 795) with Listing 5 (p. 793) and Listing 6 (p. 794) , you will see that these two methods are defined the same in both classes. Therefore, these two methods have the same behavior regardless of which of the two objects instantiated in Listing 1 (p. 789) they are called on.

Back to the driver class named Prob05

Returning now to the driver class named **Prob05** where we left off in Listing 1 (p. 789) , Listing 10 (p. 796) contains three statements that print information on the command line screen.

Listing 10 . Print three items of information.

```

System.out.print(
    ((Prob05X)var1[0]).getModifiedData() + " ");

System.out.print(randomData + " ");

System.out.println(
    ((Prob05X)var1[1]).getModifiedData());

```

Table 3.310

Three print statements

The first two statements in Listing 10 (p. 796) call the **print** method and the last statement calls the **println** method.

When the **println** method is called, the onscreen cursor advances to the left side of the next line after the material has been printed.

However, when the **print** method is called, the cursor remains at the right end of the printed material.

Therefore, calling **print print println** in succession will cause three items of information to be printed on the same line.

A cast is required

Recall that the reference to each object instantiated in Listing 1 (p. 789) is stored in an array element as type **Object** .

A reference to any object can be stored in a reference of type **Object** because the **Object** class is the superclass of all classes. (*References to array objects can also be stored as type **Object** but that fact is not germane to this program.*)

Only eleven methods can be called on type Object

However, once an object's reference is stored as type **Object** , the only methods that can be called on that object (*without casting*) are the eleven methods that are defined in the **Object** class. That group of eleven methods includes the method named **toString** but it does not include the methods named **getData** and **getModifiedData** .

Must change the type of the reference

Therefore, the first statement in Listing 10 (p. 796) requires that a **cast** to be used to change the type of the reference back to a type on which the method can be called. There are a couple of choices in this regard.

Could cast to the class type

First, it is always possible to cast the reference back to the class from which the object was instantiated. Therefore, it would work to cast the reference from array element 0 in Listing 10 (p. 796) to type **Prob05MyClassA** and to cast the reference from array element 1 to type **Prob05MyClassB** .

Cast to the interface type

In this program, there is another choice. Because both classes implement the interface named **Prob05X**, and the method named **getModifiedData** is declared in that interface, it also works to cast both references to the common interface type **Prob05X**.

That is what was done in Listing 10 (p. 796). Both references were cast to the interface type **Prob05X**.

The printed values

The first statement in Listing 10 (p. 796) calls the method named **getModifiedData** as defined in Listing 4 (p. 793). This causes the original random value *less 1* to be printed.

The second statement in Listing 10 (p. 796) simply prints the original random value that was saved in the variable named **randomData** in Listing 1 (p. 789).

The third statement in Listing 10 (p. 796) calls the method named **getModifiedData** as defined in Listing 8 (p. 795). This causes the original random value *plus 1* to be printed.

Because this is a call to the **println** method, the onscreen cursor advances to the left side of the next line after the value is printed.

The three statements in Listing 10 (p. 796) cause the first three values shown in Figure 1 (p. 788) to be printed on the command line screen.

Three more print statements

Continuing with the driver class named **Prob05**, Listing 11 (p. 797) shows three more print statements.

Listing 11 . Three more print statements.

```
System.out.print(((Prob05X)var1[0]).getData() + " ");
System.out.print(randomData + " ");
System.out.println(((Prob05X)var1[1]).getData());
```

Table 3.311

A cast is required

In this case, the **getData** method belonging to each of the objects is called in the first and third statements. (*Once again a cast is required.*)

Behavior of the getData methods is the same

Recall that the behavior of the **getData** method is the same in both objects. It simply returns a copy of the original random value that was passed to the constructor when each of the objects was instantiated.

The three statements in Listing 11 (p. 797) produce the second set of three matching values shown in Figure 1 (p. 788).

These three values match because all three print statements are printing essentially the same value. The original random value is printed in the middle statement in Listing 11 (p. 797). A copy of the original random value is printed in the first and third statements.

Print the references to the two objects

Things get a little bit more complicated in Listing 12 (p. 798).

Listing 12 . Print the references to the two objects.

continued on next page

```

        System.out.print(((Prob05X)var1[0]) + " ");
        System.out.print(randomData + 5 + " ");
        System.out.println(((Prob05X)var1[1]));

    }//end main
} //end class Prob05

```

Table 3.312

An automatic call to the toString method

Whenever an object's reference is passed to either the `print` method or the `println` method, the first thing that happens is that the `toString` method is called on the reference. The `toString` method always returns a reference to an object of the `String` class, and it is that string that is printed.

Inherited default behavior of the toString method

As I mentioned earlier, the `toString` method is defined with default behavior in the `Object` class. Since every class is a subclass of the `Object` class, every class inherits that method.

If the `toString` method is not overridden in a class or in any of the superclasses of a given class and the `toString` method is called on an object of the given class, the default behavior of the `toString` method will occur.

Can override to change the behavior

However, any class can override the `toString` method to produce different behavior and can pass that behavior down the inheritance hierarchy to subclasses of the class that overrides the method.

The toString method is overridden

In this program, the `toString` method is overridden in exactly the same way in both the `Prob05MyClassB` class and the `Prob05MyClassA` class. (See Listing 6 (p. 794) and Listing 9 (p. 795) .) Therefore, when the `toString` method is called on an object of either class, it will return a string representation of the value stored in the variable named `data` plus 5.

Pass object references to the print and println methods

The first statement in Listing 12 (p. 798) passes the reference to the object stored in the first element of the array to the `print` method and the third statement passes the reference to the object stored in the second element of the array to the `println` method.

Execute overridden toString methods and print the returned values

The `print` and `println` methods cause the code in Listing 6 (p. 794) and Listing 9 (p. 795) to be executed. In both cases, this code returns a string that represents the original random value plus 5. This is the value that is displayed.

Print the random value plus 5

The second statement in Listing 12 (p. 798) adds five to the original random number and prints the result. These three statements produce the third line of text in Figure 1 (p. 788) where all three values are the algebraic sum of the original random number plus 5.

Important - The cast is not required

Even though the references extracted from the array in the first and third statements in Listing 12 (p. 798) are cast to the interface type `Prob05X`, that cast is unnecessary.

Because the original definition of the `toString` method appears in the class named `Object`, the `toString` method can be called on those objects even while they are being treated as though they are of type `Object`.

Runtime polymorphism

Furthermore, a very powerful capability of OOP known as runtime polymorphism would cause the overridden versions of the methods defined in Listing 6 (p. 794) and Listing 9 (p. 795) to be executed instead of the default version of the method defined in the `Object` class.

The end of the main method

Listing 12 (p. 798) signals the end of the `main` method and the end of the class named `Prob05`. When the `main` method has nothing further to do, it terminates causing the program to terminate and return control to the operating system.

3.3.23.6 Run the program

I encourage you to copy the code from Listing 13 (p. 801). Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

3.3.24.3 Preview

In this module, you will learn how to scale images and how to rotate and translate images using the **AffineTransform** class.

Program specifications

Write a program named **Prob01** that uses the class definition shown in Listing 1 (p. 807) and Ericson's media library along with the image file named **Prob01.jpg** (see *Figure 1* (p. 803)) to produce the output images shown in *Figure 2* (p. 803) and *Figure 3* (p. 804) .

Figure 1 - Input file named Prob01.jpg.

Figure 2 - First output image.

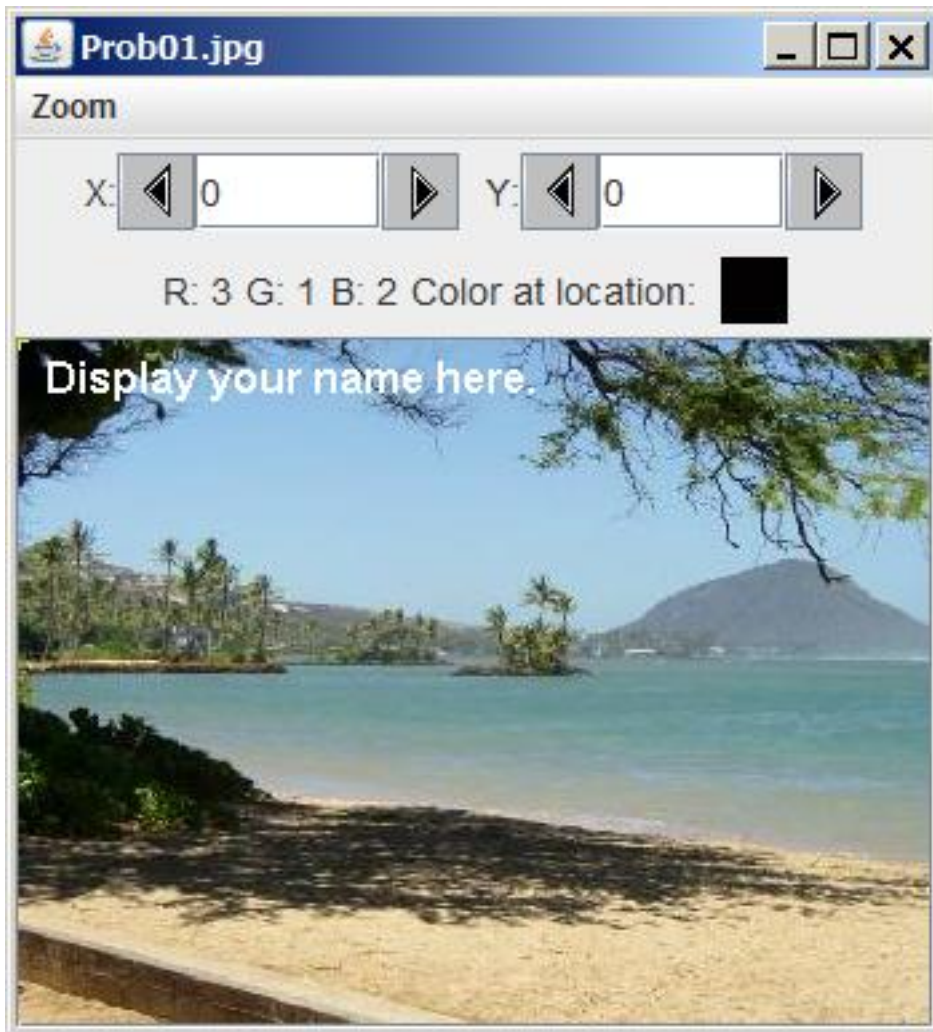

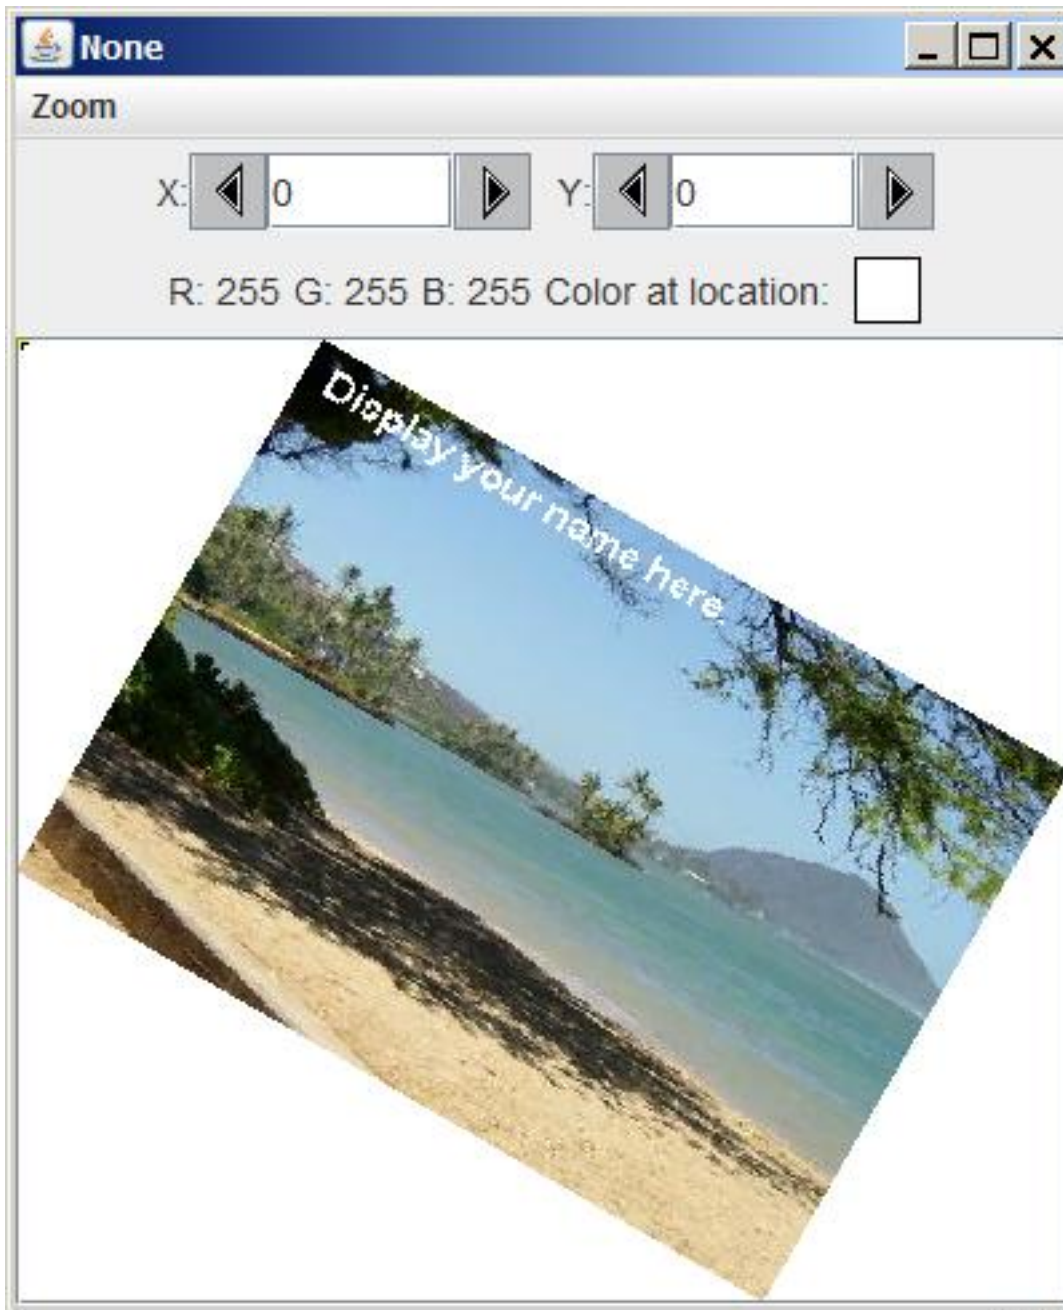

Figure 3 - Second output image.

Scale and rotate

The image from the file named **Prob01.jpg** must be scaled and then rotated 30 degrees clockwise. A scale factor of 0.95 must be applied to the horizontal and a scale factor of 0.9 must be applied to the vertical.

New classes

You may define new classes as necessary to cause your program to behave as required, but you may not modify the class definition for the class named **Prob01** shown in Listing 1 (p. 807) .

Required output text

In addition to the two output images mentioned above, your program must display your name and the other line of text shown in Figure 4 (p. 807) on the command-line screen.

Figure 4 - Required output text.
<p style="text-align: center;">Display your name here. Picture, filename None height 360 width 394</p>

Table 3.314

3.3.24.4 General background information

Writing the code from scratch to rotate an image can be a daunting task. However, the task is made much easier through the use of the standard **AffineTransform** class, which is included in the standard Java library.

The **AffineTransform** class can also be used to scale, flip, rotate, shear, and translate images.

3.3.24.5 Discussion and sample code

Will discuss in fragments

I will discuss and explain this program in fragments. A complete listing of the program is provided in Listing 10 (p. 816) near the end of the module.

The driver class named Prob01

The driver class containing the **main** method is shown in Listing 1 (p. 807) .

Listing 1 - The driver class named Prob01.
<pre> import java.awt.Graphics2D; import java.awt.geom.AffineTransform; import java.awt.geom.Rectangle2D; import java.awt.Graphics; public class Prob01{ //DO NOT MODIFY THE CODE IN THIS CLASS DEFINITION. public static void main(String[] args){ new Prob01Runner().run(); }//end main method }//end class Prob01 </pre>

Table 3.315

Instantiate a new object and call its run method

As has been the case in several earlier modules, the code in the **main** method instantiates a new object of the class named **Prob01Runner** and calls the **run** method on that object.

When the **run** method returns, the **main** method terminates causing the program to terminate.

Beginning of the class named Prob01Runner

The class named **Prob01Runner** begins in Listing 2 (p. 808) .

Listing 2 - Beginning of the class named Prob01Runner.

```

class Prob01Runner{
public Prob01Runner(){
    System.out.println("Display your name here.");
} //end constructor

```

Table 3.316

Listing 2 (p. 808) shows the constructor for the class, which simply displays the student's name on the command line screen as shown in Figure 4 (p. 807) .

The run method

The **run** method, which is called in Listing 1 (p. 807) , is shown in its entirety in Listing 3 (p. 808) .

Listing 3 - The run method.

```

public void run(){
Picture pic = new Picture("Prob01.jpg");
//Add your name and display the picture.
pic.addMessage("Display your name here.",10,20);
pic.explore();

pic = pic.scale(0.95,0.9);
pic = rotatePicture(pic,30);

pic.explore();
System.out.println(pic);
} //end run

```

Table 3.317**Mostly familiar code**

You are already familiar with all of the code in Listing 3 (p. 808) except for the call to the **scale** method and the call to the **rotatePicture** method.

The scale method

The **scale** method is part of Ericson's library. However, it is not included in the library on the CD in the back of my copy of her textbook. It is included in the zip files containing later versions, which can be downloaded from Ericson's website. (See *Java OOP: The Guzdial-Ericson Multimedia Class Library* ³⁵⁵ .)

The scale method is straightforward

When the **scale** method is called on a **Picture** object, it creates and returns a reference to a new **Picture** object that is a scaled version of the original.

Parameters

The **scale** method requires two parameters of type **double** . The first parameter is the scale factor that is applied to the horizontal dimension of the picture. The second parameter is the scale factor that is applied to the vertical dimension of the picture.

³⁵⁵<http://cnx.org/content/m44148/latest/>

Replace original picture with scaled picture

The reference to the new **Picture** object returned by the **scale** method in Listing 3 (p. 808) is stored in the variable named **pic** overwriting the reference to the original **Picture** object. From this point forward, all operations are performed on the scaled version of the original picture.

Beginning of the method named rotatePicture

The method named **rotatePicture** begins in Listing 4 (p. 809) .

Listing 4 - Beginning of the method named rotatePicture.

```
private Picture rotatePicture(Picture pic,double angle){

//Prepare the rotation transform
AffineTransform rotateTransform =
                                new AffineTransform();
rotateTransform.rotate(Math.toRadians(angle),
                       pic.getWidth()/2,
                       pic.getHeight()/2);
```

Table 3.318

Rotate and translate

The **rotatePicture** method accepts a reference to a **Picture** object along with a rotation angle in degrees.

It creates and returns a new **Picture** object that is of the correct size, containing the rotated version of the image as shown in Figure 3 (p. 804) .

The incoming image is rotated around its center by the specified rotation angle. Then it is translated to and drawn in the center of the new **Picture** object.

Affine transforms

The **rotatePicture** method uses *affine transforms* to rotate and translate the image. Affine transforms can also be used to scale images, but it is easier to scale images using Ericson's **scale** method.

However, the lack of complexity of the **scale** method is easily made up for by the complexity of affine transforms.

Google me

I have published several tutorials discussing and explaining the use of the **AffineTransform** class in Java. You can locate those modules by going to Google and searching for the following keywords:

richard baldwin affine transform

The AffineTransform class

The **AffineTransform** class is part of the standard Java library. Here is part of what the documentation³⁵⁶ has to say about the class:

"The AffineTransform class represents a 2D affine transform that performs a linear mapping from 2D coordinates to other 2D coordinates that preserves the "straightness" and "parallelness" of lines. Affine transformations can be constructed using sequences of translations, scales, flips, rotations, and shears."

The ideas behind affine transforms

One of the ideas behind affine transforms is that you can create an affine transform object and apply it to an unlimited number of other objects. This might be useful in a game program, for example, where a large number of enemy ships need to be rotated, translated, and scaled in unison.

Concatenated affine transform objects

³⁵⁶<http://java.sun.com/javase/6/docs/api/java/awt/geom/AffineTransform.html>

Another idea is that you can create two or more affine transform objects, concatenate them, and apply the concatenated transform object to an unlimited number of other objects.

Application of concatenated transform objects

Applying a concatenated transform to an object is equivalent to applying one of the transform objects to the original object and then applying the other transform objects to the transformed objects in sequential fashion. Concatenation of transform objects can result in considerable computational savings in certain situations.

A larger `Picture` object is required

Looking back at Figure 2 (p. 803) and Figure 3 (p. 804), you can see that the `Picture` object required to contain the rotated image must be larger than the `Picture` object required to contain the original image. You will learn how to compute the dimensions of the larger `Picture` object later in this module.

Behavior of the `rotatePicture` method

The `rotatePicture` method performs the following operations:

- Prepare an `AffineTransform` object that can be used to rotate the incoming image around its center by the specified angle.
- Get the dimensions of a rectangle of sufficient size to contain the rotated image.
- Prepare an `AffineTransform` object that will translate the rotated image to the center of a new, larger `Picture` object having the dimensions computed above.
- Concatenate the rotation transform object with the translation transform object.
- Create a new `Picture` object with the dimensions computed above.
- Apply the concatenated transform to the incoming image and draw the transformed image in the new `Picture` object.
- Return a reference to the new `Picture` object containing the rotated and translated image.

Prepare the rotation transform

Listing 4 (p. 809) begins by instantiating a new object of the `AffineTransform` class and saving the object's reference in the local reference variable named `rotateTransform`.

Call an overloaded `rotate` method

Then Listing 4 (p. 809) calls one of four overloaded `rotate` methods on the rotation transform object.

Three parameters are required

This version of the `rotate` method requires three parameters:

- `theta` - the angle of rotation measured in radians
- `anchorx` - the X coordinate of the rotation anchor point
- `anchory` - the Y coordinate of the rotation anchor point

To make a long story short...

The `rotate` method prepares the transform object to rotate an image around the point specified by the last two parameters.

The angle of rotation must be specified in radians.

Convert from degrees to radians

Listing 4 (p. 809) calls the static `toRadians` method of the `Math` class to convert the rotation angle from degrees to radians. The angle in radians is passed as the first parameter (*theta*) to the `rotate` method.

Compute the anchor point

Then the code in Listing 4 (p. 809) computes the coordinates of the center of the image and passes those coordinates to the `rotate` method as `anchorx` and `anchory`.

The dimensions of the new `Picture` object

How would you compute the dimensions of the new `Picture` object required to barely contain the rotated image shown in Figure 3 (p. 804)?

The computation of those dimensions is not rocket science, but would certainly require you to know quite a lot about dealing with angles and triangles.

Fortunately, we don't have to perform that computation

Ericson provides a method named `getTransformEnclosingRect` that will perform that computation for us, returning the required dimensions in the form of a reference to a standard Java `Rectangle2D` object.

Compute the dimensions of the new `Picture` object

The code in Listing 5 (p. 811) calls the `getTransformEnclosingRect` method on the previously scaled `Picture` object passing a reference to the rotation transform object to get the required dimensions for a `Picture` object that will contain the rotated image.

Listing 5 - Compute the dimensions of the new `Picture` object.

```
Rectangle2D rectangle2D =
    pic.getTransformEnclosingRect(rotateTransform);

int resultWidth = (int)(rectangle2D.getWidth());
int resultHeight = (int)(rectangle2D.getHeight());
```

Table 3.319

The dimensions of the rectangle

After getting a reference to the rectangle, Listing 5 (p. 811) gets and saves the **width** and **height** of the rectangle. These values will be used later to instantiate a new `Picture` object of the same size as the rectangle.

Prepare the translation transform

Listing 6 (p. 811) prepares a translation transform that can be used to translate the rotated image to the center of the new `Picture` object.

Listing 6 - Prepare the translation transform.

```
AffineTransform translateTransform =
    new AffineTransform();
translateTransform.translate(
    (resultWidth - pic.getWidth())/2,
    (resultHeight - pic.getHeight())/2);
```

Table 3.320

A new `AffineTransform` object

Listing 6 (p. 811) begins by instantiating a new object of the `AffineTransform` class and saving the object's reference in the local reference variable named `translateTransform`.

Call the `translate` method on the transform object

Then Listing 6 (p. 811) calls the `translate` method on the `AffineTransform` object.

According to the documentation³⁵⁷, the required parameters of the `translate` method are:

- `tx` - the distance by which coordinates are translated in the X axis direction

³⁵⁷<http://java.sun.com/javase/6/docs/api/java/awt/geom/AffineTransform.html#translate%28double,%20double%29>

- `ty` - the distance by which coordinates are translated in the Y axis direction

Compute the translation distance components

Listing 6 (p. 811) computes the distance from the center of the image to the center of the new **Picture** object and passes the X and Y components of this distance to the `translate` method.

Two AffineTransform objects

At this point, we have two different **AffineTransform** objects. One is capable of rotating the image by a specified angle. The other is capable of translating the image by a specified amount.

We could apply the two transforms sequentially to the image being careful to rotate before we translate. *(The order of rotation and translation makes a huge difference.)*

A more computationally economical approach

The preferred approach is to concatenate the two transform objects and apply only the concatenated transform object to the image. This is particularly important if the transforms are going to be applied to a large number of images such as in a game program for example.

Concatenate the transforms

Listing 7 (p. 812) calls the `concatenate` method on the translation transform passing a reference to the rotation transform as a parameter. This modifies the translation transform in such a way that it can be used to rotate the image around its center point and then translate it to the center of the new **Picture** object.

Listing 7 - Concatenate the transforms.
<pre>translateTransform.concatenate(rotateTransform);</pre>

Table 3.321

Instantiate the new Picture object

Listing 8 (p. 812) instantiates a new **Picture** object with the dimensions computed in Listing 5 (p. 811). This **Picture** object will be used to contain and return the rotated image.

Listing 8 - Instantiate the new Picture object .
<pre>Picture result = new Picture(resultWidth,resultHeight);</pre>

Table 3.322

Perform the concatenated transform

Listing 9 (p. 813) performs the rotation and translation, draws the modified image in the new **Picture** object, and returns a reference to the new **Picture** object.

Listing 9 - Perform the concatenated transform .

```

    Graphics2D g2 = (Graphics2D)result.getGraphics();

    g2.drawImage(pic.getImage(),translateTransform,null);

    return result;
} //end rotatePicture
} //end class Prob01Runner

```

Table 3.323**Call the getGraphics method**

Listing 9 (p. 813) begins by calling Ericson's `getGraphics` method on the new `Picture` object and casting the returned value to the standard type `Graphics2D` .

A cast is required

Ericson's `getGraphics` method returns a reference to the graphics context of the `Picture` object as type `Graphics` . That reference must be cast to type `Graphics2D` before the `drawImage` method can be called on the reference.

Call the drawImage method

Then Listing 9 (p. 813) calls the standard `drawImage` method on the reference to the graphics context passing three parameters to the method. This is one of two overloaded versions of the `drawImage` method defined in the standard `Graphics2D` class.

The first parameter

The first required parameter for this version of the `drawImage` method is a reference to an object of type `Image` containing the image that is to be drawn. In this case, Ericson's `getImage` method is called on the `Picture` object to get the image and pass it as the first parameter.

The second parameter

The second required parameter is a reference to an `AffineTransform` object that is to be applied to the image before it is drawn. Our concatenated transform object is passed as the second parameter.

The third parameter

The third required parameter is a reference to an object of the standard type `ImageObserver` or `null` . If you would like to know more about the use of an `ImageObserver` object, go to Google and search for the following keywords:

richard baldwin java imageobserver

We don't need an image observer in this case so Listing 9 (p. 813) passes `null` for the third parameter.

When the drawImage method returns

When the `drawImage` method returns, the image will have been rotated, translated, and drawn in the center of the new `Picture` object as shown in Figure 3 (p. 804) .

Return a Picture and terminate the method

Listing 9 (p. 813) returns a reference to the `Picture` object, (*which now contains the rotated image*) and terminates, returning control to the `run` method in Listing 3 (p. 808) .

Return to the run method

Returning to the `run` method in Listing 3 (p. 808) , we see that the remaining code in the `run` method:

- Calls Ericson's `explore` method on the returned `Picture` object producing the screen output shown in Figure 3 (p. 804) .
- Passes the returned `Picture` object to the `println` method producing the last line of text output shown in Figure 4 (p. 807) .

- Returns control the **main** method in Listing 1 (p. 807) , causing the program to terminate as soon as the user dismisses both images from the screen.

3.3.24.6 Run the program

I encourage you to copy the code from Listing 10 (p. 816) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. For example, try reversing the order of translation and rotation beginning with Listing 7 (p. 812) . Make certain that you can explain why your changes behave as they do.

Program specifications

Write a program named **Prob02** that uses the class definition shown in Listing 1 (p. 830) and Ericson's media library along with the image file named **Prob02a.jpg** (shown in Figure 1 (p. 825) (p. 825)) to produce the three graphic output images shown in Figure 2 (p. 826), Figure 3 (p. 827), and Figure 4 (p. 828).

Figure 1 - Input file named Prob02a.jpg.

³⁶⁷<http://cnx.org/content/m44148/latest/>

Figure 2 - First output image.

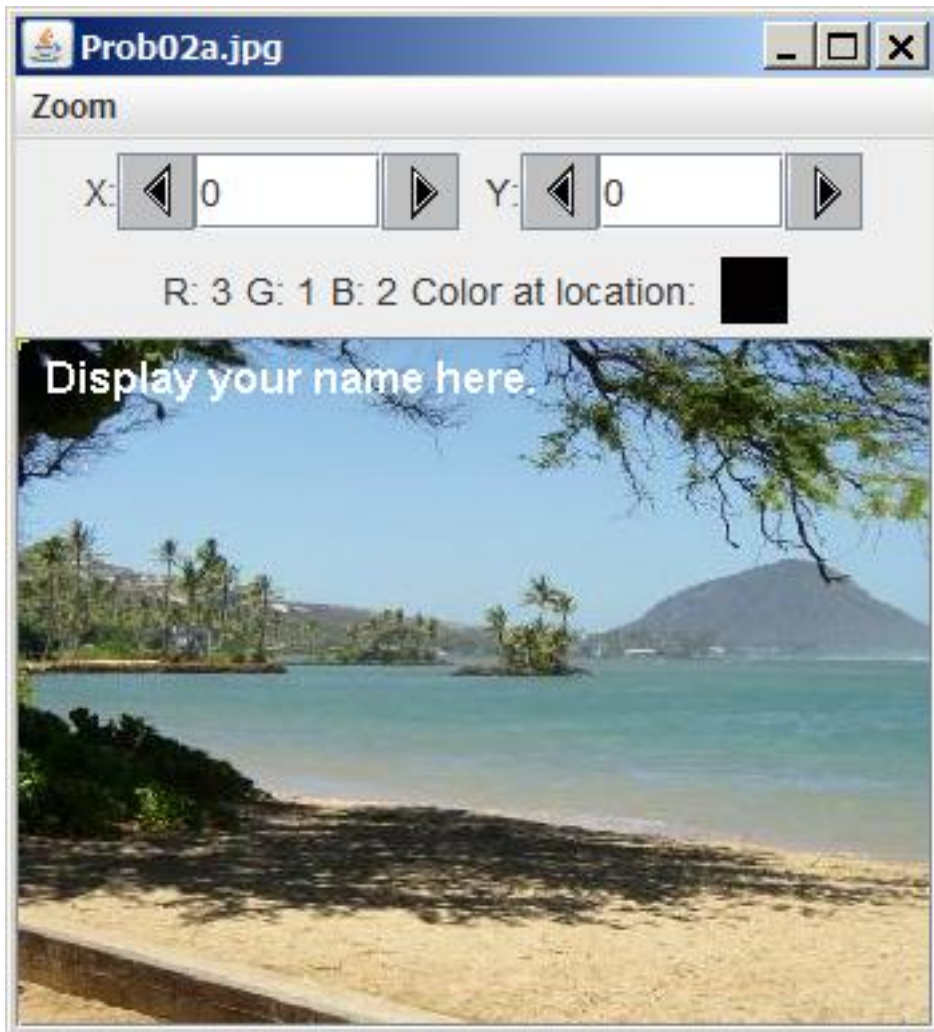

Figure 3 - Second output image.

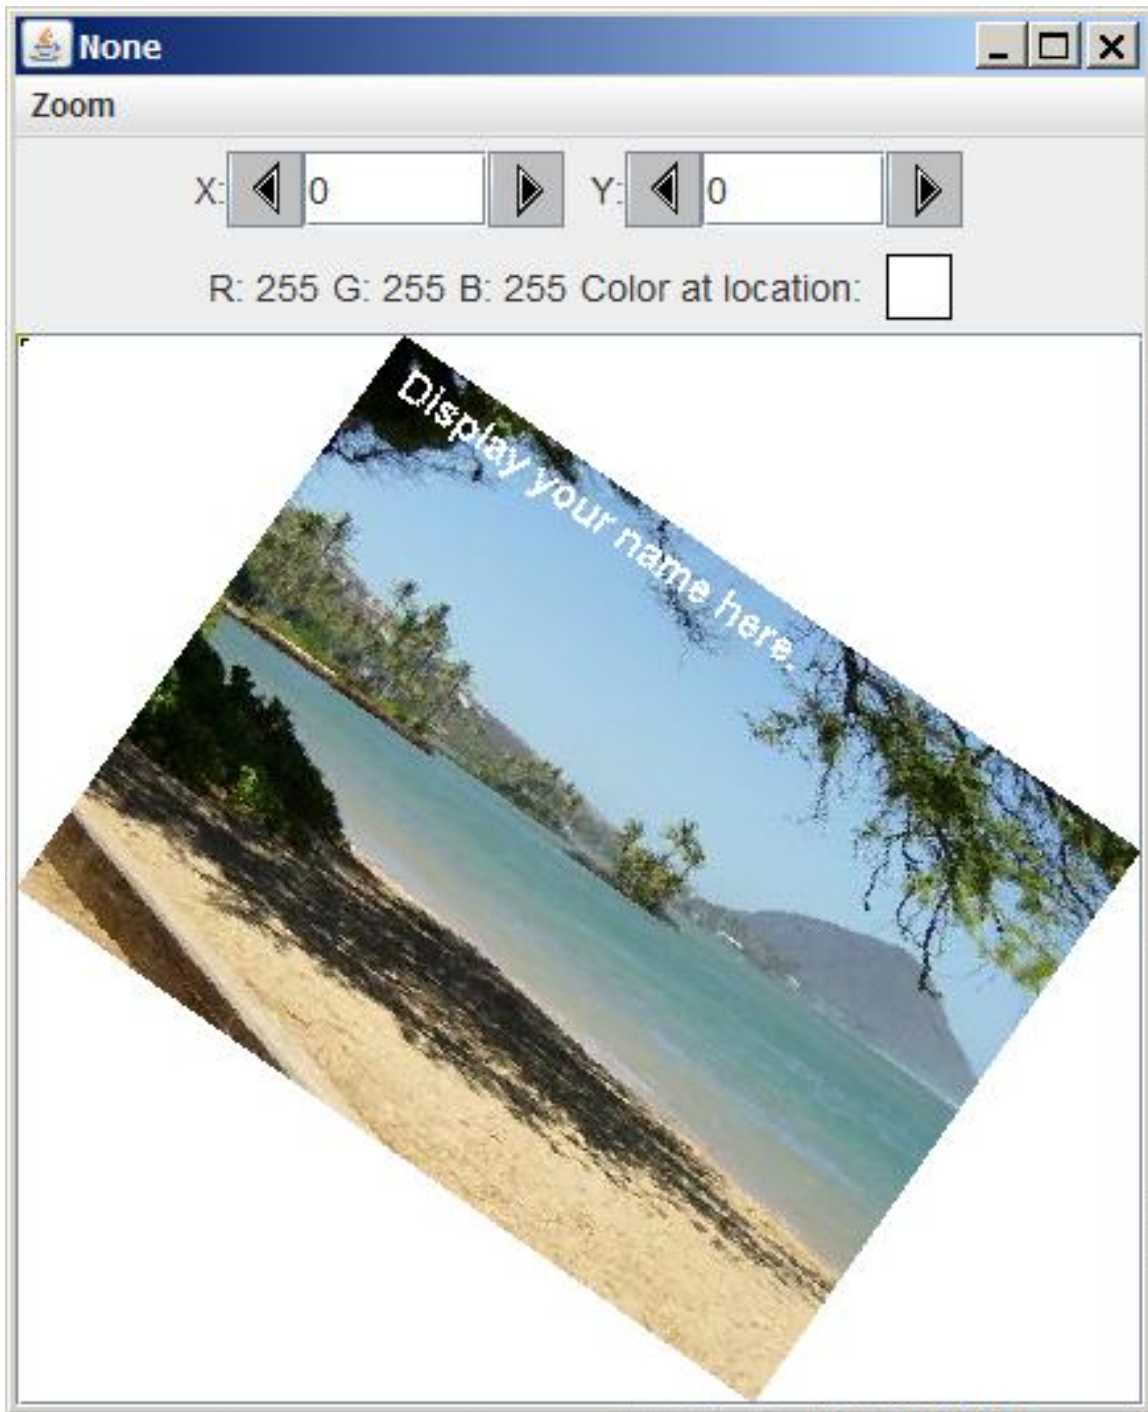

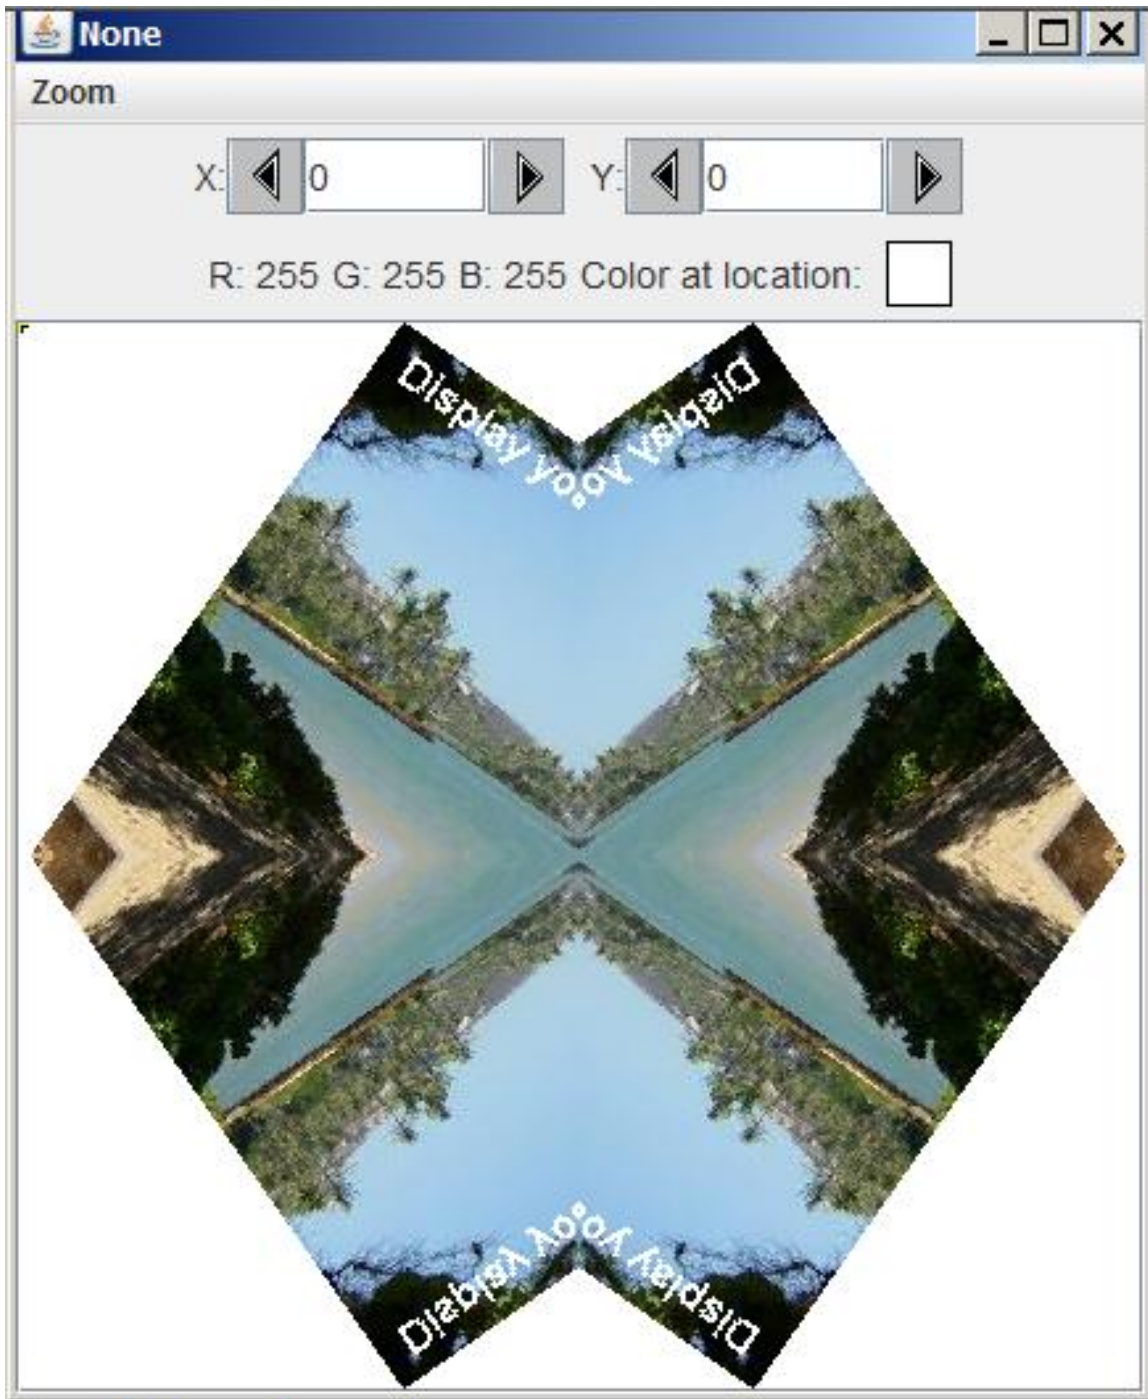

Figure 4 - Third output image.

New classes

You may define new classes as necessary to cause your program to behave as required, but you may not modify the class definition for the class named **Prob02** shown in Listing 1 (p. 830) .

Rotate and mirror

The image from the file named **Prob02a.jpg** is rotated by 35 degrees. It is not scaled. Then the top-left quadrant of the picture containing the rotated image is mirrored into the top-right quadrant. Following this, the top half of the picture is mirrored into the bottom half.

Required output text

In addition to the three output images mentioned above, your program must display your name and the other line of text shown in Figure 5 (p. 830) on the command-line screen

Figure 5 - Required output text.

3.3.26.4 Discussion and sample code**Will discuss in fragments**

I will discuss and explain this program in fragments. A complete listing of the program is provided in Listing 6 (p. 838) near the end of the module.

The driver class named Prob02

The driver class containing the **main** method is shown in Listing 1 (p. 830) .

Listing 1 - The driver class named Prob02.
<pre> public class Prob02{ public static void main(String[] args){ new Prob02Runner().run(); } //end main method } //end class Prob02 </pre>

Table 3.327

Instantiate a new object and call its run method

The code in the **main** method instantiates a new object of the class named **Prob02Runner** and calls the **run** method on that object.

When the **run** method returns, the **main** method terminates causing the program to terminate.

Beginning of the class named Prob02Runner

The beginning of the class named **Prob02Runner** , including the constructor, is shown in Listing 2 (p. 830) .

Listing 2 - Beginning of the class named Prob02Runner.
<i>continued on next page</i>

```

class Prob02Runner{
public Prob02Runner(){
    System.out.println("Display your name here.");
} //end constructor

```

Table 3.328

The constructor displays the student's name, producing the first line of output text shown in Figure 5 (p. 830) .

The run method

The **run** method that is called in Listing 1 (p. 830) is shown in its entirety in Listing 3 (p. 831) .

Listing 3 - The run method.

```

public void run(){
Picture pix = new Picture("Prob02a.jpg");
//Add your name and display the output picture.
pix.addMessage("Display your name here.",10,20);
//Display the input picture.
pix.explore();

pix = rotatePicture(pix,35);
pix.explore();

pix = mirrorUpperQuads(pix);
pix = mirrorHoriz(pix);
pix.explore();
System.out.println(pix);
} //end run

```

Table 3.329

Very familiar code

Except for the calls to the methods named **mirrorUpperQuads** and **mirrorHoriz** in Listing 3 (p. 831) , you should already be familiar with all of the code in Listing 3 (p. 831) .

The rotatePicture method

For example, the call to the method named **rotatePicture** is essentially the same as code that I explained in an earlier module. Therefore, I won't explain that method again in this module. You will find the code for the method named **rotatePicture** in Listing 6 (p. 838) near the end of the module.

Operate on the picture with the rotated image

The original picture is replaced by a picture containing the rotated image shown in Figure 3 (p. 827) . From this point forward, all operations are performed on the **Picture** object containing the rotated image.

The method named mirrorUpperQuads

The method named **mirrorUpperQuads** that is called in the **run** method in Listing 3 (p. 831) is shown in Listing 4 (p. 833) .

Behavior of the method named mirrorUpperQuads

This method mirrors the upper-left quadrant of a picture into the upper-right quadrant as shown in Figure 6 (p. 833) .

Listing 4 - The method named mirrorUpperQuads.

```

private Picture mirrorUpperQuads(Picture pix){

Pixel leftPixel = null;
Pixel rightPixel = null;
int midpoint = pix.getWidth()/2;
int width = pix.getWidth();

for(int row = 0;row < pix.getHeight()/2;row++){
for(int col = 0;col < midpoint;col++){
leftPixel = pix.getPixel(col,row);
rightPixel =
pix.getPixel(width-1-col,row);
rightPixel.setColor(leftPixel.getColor());
} //end inner loop
} //end outer loop

return pix;
} //end mirrorUpperQuads

```

Table 3.330**Declare four working variables**

Listing 4 (p. 833) begins by declaring and initializing four working variables. The purpose of these variables should be obvious on the basis of their names and their initialization expressions.

Copy the pixel colors

Then Listing 4 (p. 833) uses a double nested **for** loop to copy the colors from the pixels in the upper-left quadrant into the pixels in the upper-right quadrant. This is done in such a way as to form a mirror image about the center point as shown in Figure 6 (p. 833) .

The outer loop

The outer loop iterates on the rows of pixels in the top half of the image. Only the top half of the image is processed in this method because the top half will be mirrored into the bottom half later on.

The inner loop

The inner loop iterates on the columns in the left half of the image, copying pixel colors from the left half into the pixels in the right half.

Destruction of pixel colors

The colors in the pixels in the upper-right quadrant are overwritten by this method.

In effect, this method and the one following it destroys all of the pixel colors originally in the right half of the picture of the rotated image and all of the pixel colors originally in the bottom half of the picture.

The final picture shown in Listing 4 (p. 833) contains only pixel from the upper-left quadrant of the picture with the rotated image.

Return a modified Picture object

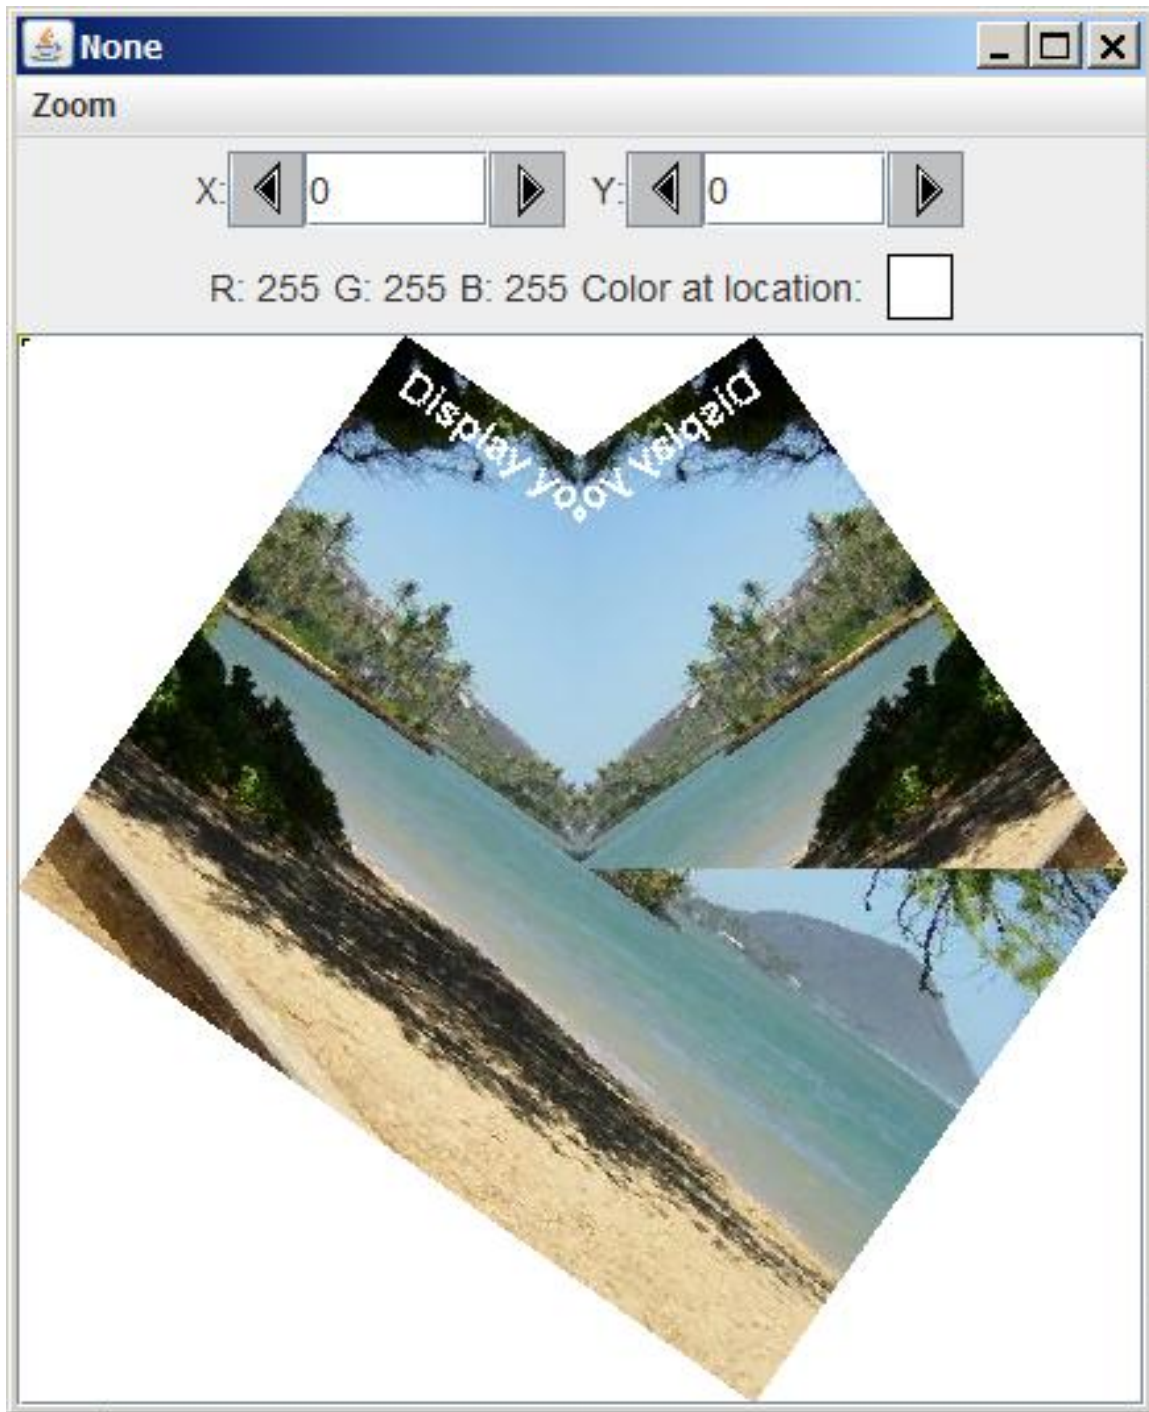

Finally, the code in Listing 4 (p. 833) returns the modified **Picture** object to the **run** method in Listing 3 (p. 831) .

At this point, the picture with the rotated image is replaced by the version of the picture returned by the **mirrorUpperQuads** method.

Picture output from the mirrorUpperQuads method

If you were to display the picture at that point, you would see the image shown in Figure 6 (p. 833) .

Figure 6 - Picture output from the mirrorUpperQuads method.

The upper-left quadrant has been mirrored

As you can see from Figure 6 (p. 833) , at this point in the process, the upper-left quadrant has been mirrored into the upper-right quadrant, but the bottom half of the picture is undisturbed. It's time to do something about that.

Call the `mirrorHoriz` method

The next statement in the `run` method in Listing 3 (p. 831) is a call to the `mirrorHoriz` method

passing the picture shown in Figure 6 (p. 833) as a parameter.

The method named `mirrorHoriz`

The method named `mirrorHoriz` is shown in Listing 5 (p. 835) . This method mirrors the top half of a picture into the bottom half of the same picture. It will be used to mirror the top half of the picture in Figure 6 (p. 833) into the bottom half.

Listing 5 - The method named `mirrorHoriz`.

```
private Picture mirrorHoriz(Picture pix){

    Pixel topPixel = null;
    Pixel bottomPixel = null;
    int midpoint = pix.getHeight()/2;
    int height = pix.getHeight();

    for(int col = 0;col < pix.getWidth();col++){
        for(int row = 0;row < midpoint;row++){
            topPixel = pix.getPixel(col,row);
            bottomPixel =
                pix.getPixel(col,height-1-row);
            bottomPixel.setColor(topPixel.getColor());
        }//end inner loop
    }//end outer loop

    return pix;
} //end mirrorHoriz method

} //end class Prob02Runner
```

Table 3.331

Very similar to the `mirrorUpperQuads` method

This method is very similar to the previous method named `mirrorUpperQuads` .

Four working variables and a nested for loop

As before, Listing 5 (p. 835) declares and initializes four working variables. These variables are used in a nested `for` loop to copy pixel colors from the top half of the picture into the pixels in the bottom half.

The outer and inner loops

In this case, the outer loop iterates on all of the columns going from left to right.

The inner loop iterates on rows, from the top row to the vertical midpoint, copying the colors from the pixels from the top half into the pixels in the bottom half.

The end of the class

Listing 5 (p. 835) also signals the end of the class named `Prob02Runner` and the end of the program.

3.3.26.5 Run the program

I encourage you to copy the code from Listing 6 (p. 838) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

3.3.28.3 Preview

In this module you will learn to use the **GradientPaint** class along with a variety of other Java2D classes.

Program specifications

Write a program named **Prob03** that uses the class definition shown in Listing 1 (p. 850) and Ericson's media library along with the image file named **Prob03.jpg** to produce the graphic output image shown in Figure 1 (p. 848) . *(Note that the image in the file named Prob03.jpg is a blank white image. You could also create this blank image using one of the constructors for the **Picture** class.)*

Figure 1 - Required graphic output.

Circles with gradient paint

The program draws four circles in the quadrants of a Cartesian coordinate system. One is filled with solid green. The other three are filled with cyclic gradient paint from green to blue.

The number of cycles varies in each circle, as do the axes along which the gradient occurs.

The background is set to `Color.RED`.

New classes

You may define new classes as necessary to cause your program to behave as required, but you may not modify the class definition for the class named **Prob03** shown in Listing 1 (p. 850) .

Required text output

In addition to the output image mentioned above, your program must display your name and the other line of text shown in Figure 2 (p. 850) .

Figure 2 - Required text output.

```

    Display your name here.
Picture, filename Prob03.jpg height 300 width 300

```

Table 3.334**3.3.28.4 Discussion and sample code****Will discuss in fragments**

I will discuss and explain this program in fragments. A complete listing of the program is provided in Listing 9 (p. 862) near the end of the module.

The driver class named Prob03

The driver class containing the main method is shown in Listing 1 (p. 850) .

Listing 1 - The driver class named Prob03.

```

    public class Prob03{
    public static void main(String[] args){
        new Prob03Runner().run();
    }//end main method
} //end class Prob03

```

Table 3.335

If you have been studying the earlier modules in this series, no explanation of Listing 1 (p. 850) should be required.

Beginning of the class named Prob03Runner

The class named **Prob03Runner** begins in Listing 2 (p. 851) .

Listing 2 - Beginning of the class named Prob03Runner.

```

class Prob03Runner{
public Prob03Runner(){
    System.out.println("Display your name here.");
} //end constructor
//-----//

public void run(){
    Picture pic = new Picture("Prob03.jpg");
// Picture pic = new Picture(300,300);

    pic.setAllPixelsToAColor(Color.RED);

    process(pic);

    //Add your name and display the output picture.
    pic.addMessage("Display your name here.",10,20);
    pic.explore();
    System.out.println(pic);
} //end run

```

Table 3.336**Avoiding use of a blank input image file**

This program was originally written using an early version of Ericson's class library that didn't support the second statement in the **run** method. (*That statement was disabled by turning it into a comment in Listing 2 (p. 851) (p. 851)*) As a result, with that library, it was necessary to read an image file containing a blank white image to create a **Picture** object with a blank white image.

No longer a problem

That problem was rectified with an update to her library and the disabled statement can be substituted for the statement immediately above it. If you do that, you won't need the input image file.

Except for that, and the call to the method named **process**, you should already understand all of the code in Listing 2 (p. 851).

Beginning of the method named process

The method named **process** begins in Listing 3 (p. 851).

Listing 3 - Beginning of the method named process.

```

private void process(Picture pic){

Graphics2D g2 = (Graphics2D)(pic.getGraphics());

int width = pic.getWidth();
int height = pic.getHeight();

```

Table 3.337

Java2D graphics

This is basically a module on the use of classes from the Java2D section of the standard class library. (See my lessons 300 through 324 on Java2D graphics here ³⁷⁸.) Classes from Ericson's library are used mainly to support the display aspects of the program.

What are Java2D graphics?

Although the capabilities provided by Java2D graphics are wide and varied, in one way or another, they generally have to do with the creation of images by drawing.

A graphics context is required

In order to use the methods that will be using, it is necessary to gain access to the graphics context of an object as type `Graphics2D`. The first statement in Listing 3 (p. 851) calls Ericson's `getGraphics` method to gain access to the graphics context of a `Picture` object.

A cast to type Graphics2D is required

However, the `getGraphics` method returns a reference to the graphics context as type `Graphics`. In order for us to use it to do what we want to do, we must cast it to type `Graphics2D`. This gives us access to many more methods that would be the case without the cast.

Save as type Graphics2D in a variable named g2

The graphics context for the `Picture` object is saved in Listing 3 (p. 851) as type `Graphics2D`. The reference is saved in the reference variable named `g2`.

Save the width and height of the Picture object

The last two statements in Listing 3 (p. 851) get and save the `width` and the `height` of the image encapsulated in the `Picture` object.

Translate the origin to the center of the image

By default, the origin (*with coordinates of 0,0*) is in the upper-left corner of the image. However, we would like to be able to work with a coordinate system in which the origin is at the center.

Listing 4 (p. 852) calls the `translate` method to move the origin to the center of the image.

Listing 4 - Translate the origin to the center of the image.
<pre>g2.translate(width/2,height/2);</pre>

Table 3.338

(Fortunately, you already understand affine transforms. Otherwise, you might not be able to understand the documentation for the `translate` method.)

From this point forward...

From this point forward, we can think of the coordinates of the pixel at the very center of the object as having values of 0,0. Locations to the left of center have negative X coordinates and locations above the center have negative Y coordinates.

Draw the black horizontal and vertical axes

The next thing we want to do is to draw the black horizontal and vertical axes that you see in the center of the image in Figure 1 (p. 848). This is accomplished by the code in Listing 5 (p. 852).

Listing 5 - Draw the black horizontal and vertical axes.

//Draw x-axis
g2.draw(new Line2D.Double(-width/2, 0.0,
                          width/2, 0.0));

                          0.0, height/2));

```

Table 3.339

Set the drawing color to black

Listing 5 (p. 852) begins by calling the `setColor` method to set the drawing color to `Color.BLACK`. (*BLACK is a static constant in the `Color` class that represents the color black.*)

A new `Line2D.Double` object

The fourth line of code in Listing 5 (p. 852) instantiates a new object of the `Line2D.Double` class. This object represents a line extending between two points specified by coordinate values passed as parameters to the constructor.

A black horizontal line

The first pair of coordinate values specifies the left end of the black horizontal line in Figure 1 (p. 848). The second pair of coordinate values specifies the right end of the black horizontal line in Figure 1 (p. 848). (See my Lesson Number 300³⁷⁹ for an explanation of the somewhat unusual name of a class consisting of two words separated by a period: `Line2D.Double`.)

Pass the line object to the `Draw` method

The new object's reference is passed to the `draw` method, which is responsible for causing the line to be drawn on the graphics context.

A black vertical axis

The last statement in Listing 5 (p. 852) draws the black vertical line shown in Figure 1 (p. 848).

Coordinates relative to the origin at the center

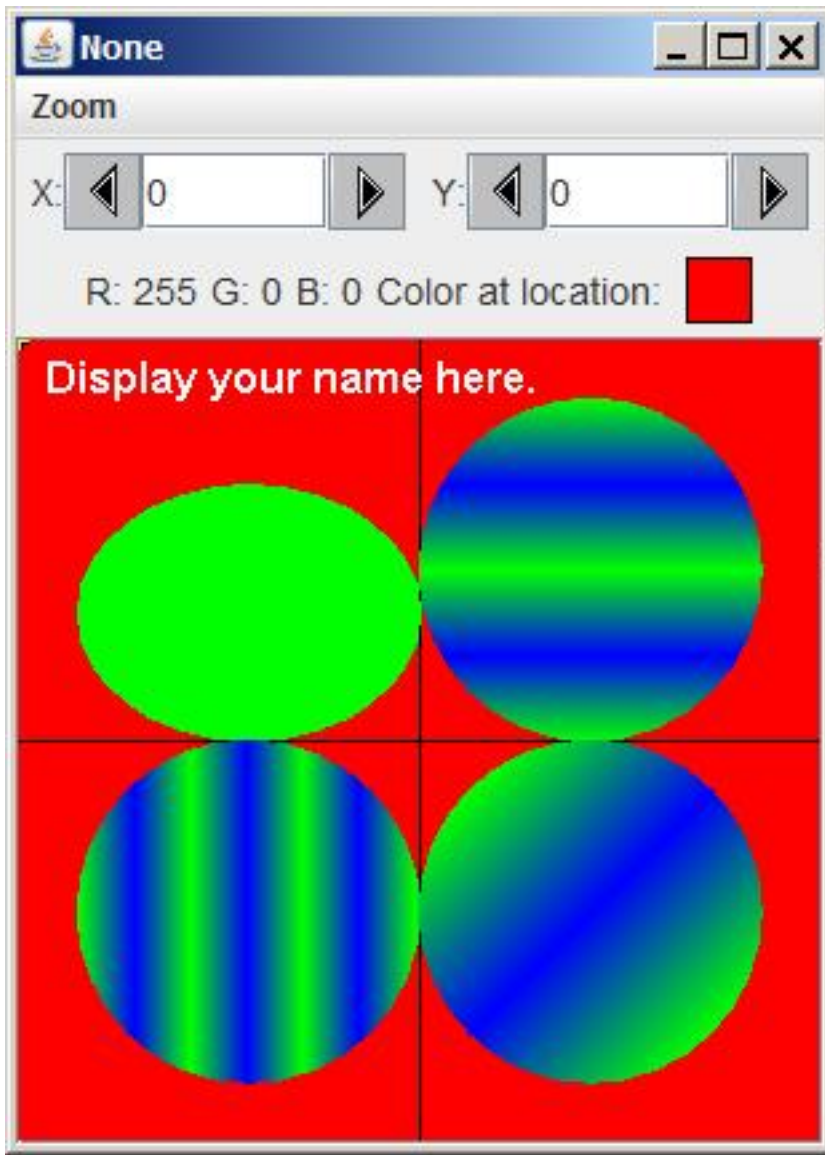

Note that in both cases, the end points of the line are specified using coordinate values that are relative to the origin, which is positioned at the center of the drawing context.

Draw the solid green filled ellipse in the upper-left quadrant

In case you are unfamiliar with the term, an *ellipse* is the 2D shape shown in the upper-left quadrant of Figure 3 (p. 853). A circle is an ellipse with the major and minor axes having the same lengths.

Figure 3 - A drawing of an ellipse.

³⁷⁹<http://www.dickbaldwin.com/java/Java300.htm>

There is no circle class

Java does not provide a `Circle2D.Double` class but it does provide an `Ellipse2D.Double` class, which you can use to draw circles.

(The `Graphics` class also provides a `drawOval` method that can be used to draw circles but those circles won't suffice for what we will be doing in this module.)

Four constructor parameters

The constructor for the `Ellipse2D.Double` class requires four parameters of type `double`. The first two parameters are the X and Y coordinates of the upper-left corner of an imaginary rectangle.

The next two parameters are the **width** and the **height** of the imaginary rectangle.

The sides of the imaginary rectangle are parallel to the X and Y axes, but can be rotated using affine transforms.

An ellipse inside an imaginary rectangle

The ellipse is constructed inside the imaginary rectangle such that it is symmetrical about its horizontal and vertical axes and it touches all four sides of the rectangle. *(The documentation refers to the rectangle as a framing rectangle.)*

How do you construct a circle?

If the rectangle is actually a square, then the ellipse becomes a circle.

Construct an ellipse inside an imaginary square

The first statement in Listing 6 (p. 855) constructs an object of type `Ellipse2D.Double` inside a 128x128 square that just fits in the upper left quadrant of our Cartesian coordinate system shown in Figure 1 (p. 848) . The circle object's reference is saved in the reference variable named `circle1` .

Listing 6 - Draw the solid green filled ellipse in the upper-left quadrant.

```
//Upper left quadrant
Ellipse2D.Double circle1 =
    new Ellipse2D.Double(-128,-128,128,128);

//Solid GREEN fill
g2.setPaint(Color.GREEN);

g2.fill(circle1);

g2.draw(circle1);
```

Table 3.340**Set the painting color**

The statement near the middle of Listing 6 (p. 855) sets the painting color to `Color.GREEN` .

(Note that Listing 6 (p. 855) (p. 855) calls `setPaint` whereas Listing 5 (p. 852) calls `setColor` . I will leave it as an exercise for the student to study the documentation in order to understand the difference between `setColor` and `setPaint` .)

Fill the circle referred to by circle1

The second statement from the bottom in Listing 6 (p. 855) calls the `fill` method of the `Graphics2D` class passing the circle object's reference as a parameter. Although this can get quite complex, in this simple case, it causes the circle object to be filled with the paint color (*green*) .

Draw the filled circle object

Finally, the last statement in Listing 6 (p. 855) calls the `draw` method of the `Graphics2D` class to cause the filled circle to be drawn inside the framing rectangle that was specified when the circle was constructed. This results in the filled green circle in the upper-left quadrant in Figure 1 (p. 848) .

Draw a circle with a gradient fill in the upper-right quadrant

This is where things tend to get a little complicated.

If you compare the circles in the upper-left and upper-right quadrants in Figure 1 (p. 848) , you will see that they look considerably different.

Difference caused by parameter to the setPaint method

If you compare the code in Listing 6 (p. 855) with the code in Listing 7 (p. 856) , you will see that except for the coordinate values that position the circle, the only difference is the parameter that is passed to the `setPaint` method.

Listing 7 - Draw a circle with a gradient fill in the upper-right quadrant.

```

    //Upper right quadrant
    //Gradient GREEN to BLUE, cyclic along horizontal
    // axis.
    Ellipse2D.Double circle2 =
        new Ellipse2D.Double(0.0,-128,128,128);
    g2.setPaint(new GradientPaint(
        64,0,Color.GREEN,
        64,-32,Color.BLUE,true));
    g2.fill(circle2);
    g2.draw(circle2);

```

Table 3.341**A simple color paint versus a gradient paint**

Listing 6 (p. 855) passes an object of the simple **Color** class representing the color green to the **setPaint** method.

Listing 7 (p. 856) passes an object of the **GradientPaint** class to the **setPaint** method.

Therefore, we need to understand the behavior of an object of the **GradientPaint** class.

Constructor parameters

There are four overloaded constructors for the **GradientPaint** class. The constructor used in Listing 7 (p. 856) is one of the most complicated. It requires the following parameters:

- x1 - x coordinate of the first specified Point in user space
- y1 - y coordinate of the first specified Point in user space
- color1 - Color at the first specified Point
- x2 - x coordinate of the second specified Point in user space
- y2 - y coordinate of the second specified Point in user space
- color2 - Color at the second specified Point
- cyclic - true if the gradient pattern should cycle repeatedly between the two colors; false otherwise

Two points and two colors

Basically, the class allows you to specify two points and two colors (*plus one additional boolean parameter*) when you construct an object of the class.

One of the colors is associated with each point.

An imaginary line segment

Think of the two points as being at the ends of an imaginary line segment, which can be at any angle relative to the horizontal.

Colors at the ends of the line segment

When a shape is drawn using a gradient fill, one of the colors will appear at one end of the line segment and the other color will appear at the other end of the line segment.

The color will change

The color will change gradually from one color to the other along the imaginary line segment connecting the two points.

Perpendicular color bands on the sides

The colors extend out to the sides of the imaginary line segment in bands that are perpendicular to the line segment.

The cyclic parameter

If the last (*cyclic*) parameter is set to false, the color will only change along the imaginary line segment. Areas beyond each end of the line segment will be the colors that are specified for the points at the ends of the line segment.

(This parameter was not set to false for any of the circles in Figure 1 (p. 848) .)

If the cyclic parameter is true...

The pattern of color change that occurs along the line segment will extend in a cyclic fashion beyond the ends of the line segment all the way to infinity.

Compare constructor parameters with upper-right quadrant

Now consider the parameter values used in Listing 7 (p. 856) and compare them with the image in the upper-right quadrant in

A simple color paint versus a gradient paint

Listing 6 (p. 855) passes an object of the simple **Color** class representing the color green to the **setPaint** method.

Listing 7 (p. 856) passes an object of the **GradientPaint** class to the **setPaint** method.

Therefore, we need to understand the behavior of an object of the **GradientPaint** class.

Constructor parameters

There are four overloaded constructors for the **GradientPaint** class. The constructor highlighted in yellow in Listing 7 (p. 856) is one of the most complicated. It requires the following parameters:

- x1 - x coordinate of the first specified Point in user space
- y1 - y coordinate of the first specified Point in user space
- color1 - Color at the first specified Point
- x2 - x coordinate of the second specified Point in user space
- y2 - y coordinate of the second specified Point in user space
- color2 - Color at the second specified Point
- cyclic - true if the gradient pattern should cycle repeatedly between the two colors; false otherwise

Two points and two colors

Basically, the class allows you to specify two points and two colors (*plus one additional boolean parameter*) when you construct an object of the class.

One of the colors is associated with each point.

An imaginary line segment

Think of the two points as being at the ends of an imaginary line segment, which can be at any angle relative to the horizontal.

Colors at the ends of the line segment

When a shape is drawn using a gradient fill, one of the colors will appear at one end of the line segment and the other color will appear at the other end of the line segment.

The color will change

The color will change from one color to the other along the imaginary line segment connecting the two points.

Perpendicular color bands on the sides

The colors extend out to the sides of the imaginary line segment in bands that are perpendicular to the line segment.

The cyclic parameter

If the last (*cyclic*) parameter is set to false, the color will only change along the imaginary line segment. Areas beyond each end of the line segment will be the colors that are specified for the points at the ends of the line segment.

(This parameter was not set to false for any of the circles in Figure 1 (p. 848) .)

If the cyclic parameter is true...

The pattern of color change that occurs along the line segment will extend in a cyclic fashion beyond the ends of the line segment all the way to infinity.

Compare constructor parameters with upper-right quadrant

Now consider the parameter values used in Listing 7 (p. 856) and compare them with the image in the upper-right quadrant in Figure 1 (p. 848) .

The location of the first point

The diameter of each circle in Figure 1 (p. 848) is 128 pixels. The first point for the upper-right quadrant in Figure 1 (p. 848) is on the X axis at the point where the circle touches the X axis. This point is specified to have a color of green.

The location of the second point

The second point is 32 pixels directly above the first point. Therefore, the imaginary line segment is perpendicular to the X axis. It extends from the X axis one-fourth of the way to the top of the circle. The second point is specified to have a color of blue.

The color change

As a result, the color changes from green to blue along the 32-pixel line segment. Color bands extend to the right and left, perpendicular to the line segment.

The cyclic parameter

The cyclic parameter is set to true, so the pattern repeats along the remaining vertical dimension of the circle. The color changes from blue back to green along the next 32-pixel vertical distance causing the circle to be green at the center.

The pattern repeats again resulting in a blue band three-fourths of the way from the bottom to the top of the circle and a green band at the top of the circle.

That's all there is to it

Now that you know the scheme, you should be able to examine the code in Listing 8 (p. 859) for the remaining two quadrants and understand how the constructor parameters resulted in the color patterns that you see in Figure 1 (p. 848) .

Listing 8 - Code for the remaining two quadrants.

```

        //Lower left quadrant
        //Gradient GREEN to BLUE, cyclic along vertical axis.
        //horizontal axis
        Ellipse2D.Double circle3 =
            new Ellipse2D.Double(-128,0.0,128,128);
        g2.setPaint(
            new GradientPaint(
                -128,-64,Color.GREEN,
                -107,-64,Color.BLUE,true));
        g2.fill(circle3);
        g2.draw(circle3);

        //Lower right quadrant
        //Gradient GREEN to BLUE, cyclic along
        // 45 degree angle
        Ellipse2D.Double circle4 =
            new Ellipse2D.Double(0,0,128,128);
        g2.setPaint(
            new GradientPaint(
                19,19,Color.GREEN,
                64,64,Color.BLUE,true));

        g2.fill(circle4);
        g2.draw(circle4);

    } //end process
} //end class Prob03Runner

```

Table 3.342**An interesting anomaly**

I will point out one interesting anomaly, however. Even though we shifted the origin to the center, we did not change the direction that represents positive values on the Y axis.

Coordinates above the center are negative and coordinates below the center are positive.

Where is the line segment?

If you examine the constructor parameters for the lower-left quadrant in Listing 8 (p. 859) , you will see that the imaginary line segment isn't in the lower-left quadrant.

The line segment is 21 pixels in length, parallel to the horizontal axis. However, it is 64 pixels above the horizontal axis. That is not in the lower-left quadrant.

The effect is...

The effect is as though the color gradient fills the universe, and is based on a line segment placed anywhere in the universe.

However, we only see the color gradient through the shape that we specify as a parameter to the **fill** method. In other words, that shape is a window through which we can see a background consisting of gradient color changes.

Our window is in the lower-left quadrant

In this case, that shape is the circle in the lower-left quadrant, so we see the gradient color effect in the lower-left quadrant.

How about the bottom-right quadrant

I stated earlier that the imaginary line segment can be at any angle relative to the horizontal axis.

For the bottom right quadrant, the line segment is 64 pixels in length. It lies along a line that goes through the origin and is at 45 degrees clockwise relative to the horizontal.

Where is the line segment positioned?

One end of the line segment is at the center of the circle. The other end of the line segment is at the point where the 45-degree line intersects the edge of the circle closest to the origin.

You can take it from there

You should be able to take it from there and explain the color gradient in the circle in the lower-right quadrant. Recall that the diameter of the circle is 128 pixels. The length of the line segment is 64 pixels or one-half the diameter.

The end of the class

Listing 8 (p. 859) signals the end of the class named **Prob03Runner** and the end of the program.

3.3.28.5 Run the program

I encourage you to copy the code from Listing 9 (p. 862) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. For example, try setting the cyclic constructor parameter to false and observe the effect. Make certain that you can explain why your changes behave as they do.

3.3.30.3 Preview

In this module, you will learn how to use shapes to clip images during the drawing process.

Program specifications

Write a program named **Prob04** that uses the class definition shown in Listing 1 (p. 874) and Ericson's media library along with the image file named **Prob04a.jpg** (see *Figure 1* (p. 870)) to produce the graphic output images shown in Figure 2 (p. 871) and Figure 3 (p. 872). Don't forget to display your name in the output image as shown.

Figure 1 - Input file named Prob04a.jpg.

³⁸⁹<http://cnx.org/content/m44148/latest/>

Figure 2 - First output image.

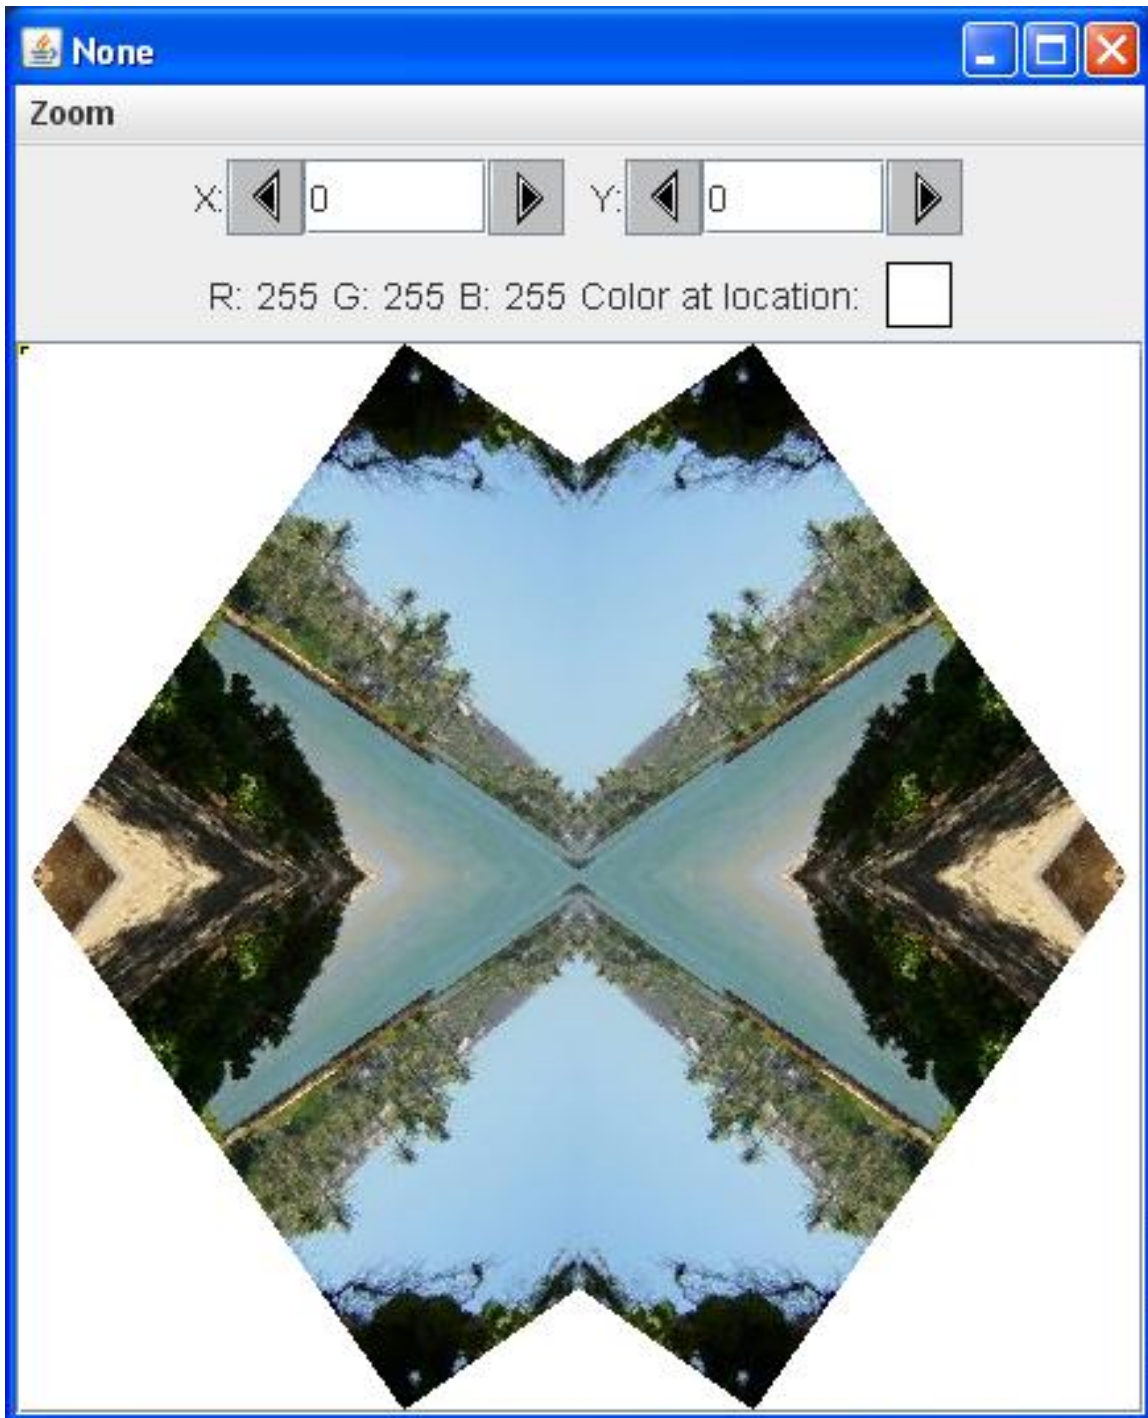

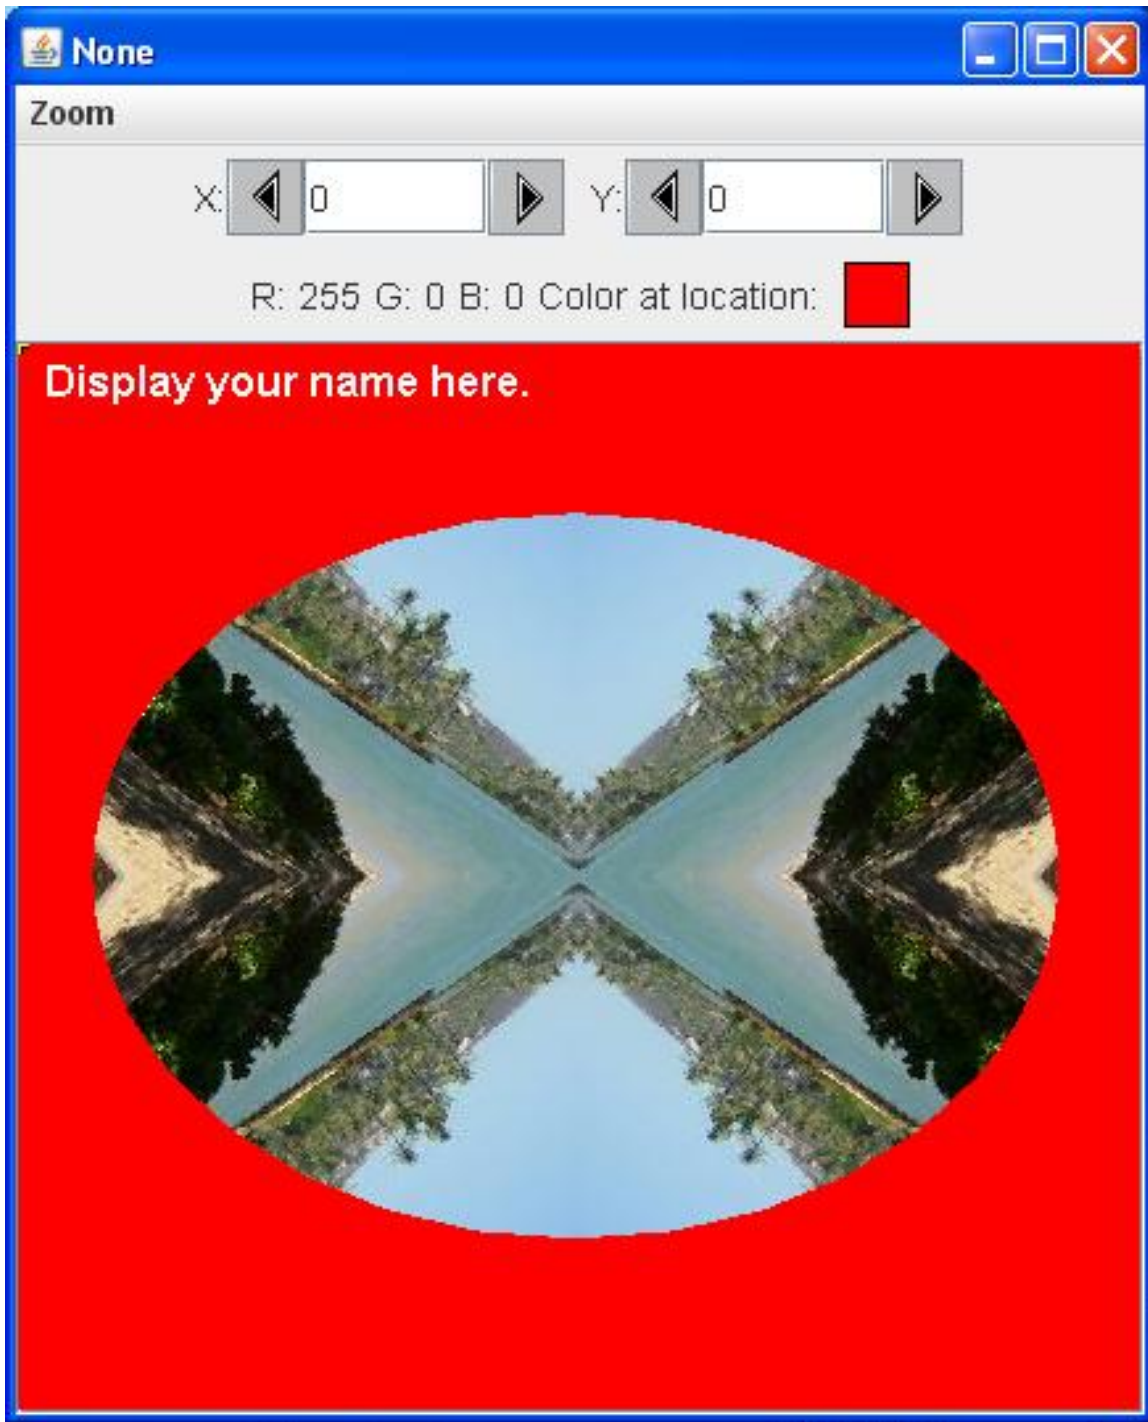

Figure 3 - Second output image.

New classes

You may define new classes as necessary to cause your program to behave as required, but you may not modify the class definition for the class named **Prob04** shown in Listing 1 (p. 874) .

Rotate, mirror, and clip

The program rotates a **Picture** object by 35 degrees with no scaling. Then it does a four-way mirror on the rotated picture. Finally, it clips the image to an elliptical format as shown in Figure 3 (p. 872) .

Required output text

In addition to the two output images shown above, your program must display your name and the other line of text shown in Figure 4 (p. 874) .

Figure 4 - Required text output.
<p>Display your name here. Picture, filename None height 404 width 425</p>

Table 3.345

3.3.30.4 Discussion and sample code**Will discuss in fragments**

I will discuss and explain this program in fragments. A complete listing of the program is provided in Listing 5 (p. 879) near the end of the module.

The driver class named Prob04

The driver class containing the **main** method is shown in Listing 1 (p. 874) .

Listing 1 - The driver class named Prob04.
<pre> public class Prob04{ public static void main(String[] args){ new Prob04Runner().run(); } //end main method } //end class Prob04 </pre>

Table 3.346

If you have been studying the earlier modules in this collection, no explanation of Listing 1 (p. 874) should be required.

Beginning of the class named Prob04Runner

The class named **Prob04Runner** begins in Listing 2 (p. 875) .

Listing 2 - Beginning of the class named Prob04Runner.

```

class Prob04Runner{

public Prob04Runner(){
    System.out.println("Display your name here.");
} //end constructor
//-----//

public void run(){
    Picture pix = new Picture("Prob04a.jpg");

    //Rotate and mirror the picture.
    pix = rotatePicture(pix,35);
    pix = mirrorUpperQuads(pix);
    pix = mirrorHoriz(pix);

    pix.explore();
}
}

```

Table 3.347**Nothing new here**

There is nothing new in Listing 2 (p. 875) .

After instantiating a new **Picture** object from the given image file, Listing 2 (p. 875) calls three methods to rotate, mirror, and display the picture, producing the graphic output shown in Figure 2 (p. 871)

All of the code to accomplish this is essentially the same as code that I have explained in earlier modules.

Clip the picture and display your name

Then Listing 3 (p. 875) calls the **clipToEllipse** method to clip the picture to an ellipse on a red background as shown in Figure 3 (p. 872) . The **clipToEllipse** method is new to this module, so I will explain it shortly.

Listing 3 - Clip the picture and display your name.

```

    pix = clipToEllipse(pix);

    //Add your name and display the output picture.
    pix.addMessage("Display your name here.",10,20);
    pix.explore();

    System.out.println(pix);
} //end run

```

Table 3.348

The remaining code in Listing 3 (p. 875) is a repeat of code that I have explained in earlier modules, so I won't have anything further to say about it.

The method named `clipToEllipse`

The method named `clipToEllipse` is shown in its entirety in Listing 4 (p. 876) .

Listing 4 - The method named `clipToEllipse`.

```

private Picture clipToEllipse(Picture pix){
Picture result =
    new Picture(pix.getWidth(),pix.getHeight());
result.setAllPixelsToAColor(Color.RED);

//Get the graphics2D object
Graphics2D g2 = (Graphics2D)(result.getGraphics());

//Create an ellipse for clipping
Ellipse2D.Double ellipse =
    new Ellipse2D.Double(28,64,366,275);

//Use the ellipse for clipping
g2.setClip(ellipse);

//Draw the image
g2.drawImage(pix.getImage(),0,0,pix.getWidth(),
            pix.getHeight(),
            null);

return result;
} //end clipToEllipse

```

Table 3.349

Behavior of the `clipToEllipse` method

The `clipToEllipse` method receives an incoming parameter that is a reference to an object of the `Picture` class. Basically, here is what the method does:

- Instantiate a `Picture` object with an all white background that is the same size as the incoming `Picture` object.
- Call Ericson's `setAllPixelsToAColor` method to convert the white background into a red background.
- Call Ericson's `getGraphics` method to get the `Graphics` object encapsulated in the red `Picture` object.
- Cast the `Graphics` object's reference to type `Graphics2D` .
- Construct a new `Ellipse2D.Double` object with the position, width, and height specified by the constructor parameters.
- Call Sun's `setClip` method to set the clipping area on the red `Picture` object to match the position and shape of the ellipse.
- Call Ericson's `getImage` method to get the `Image` object encapsulated in the incoming `Picture` object.
- Call Sun's `drawImage` method to draw that portion of the incoming picture that fits inside the ellipse on the red `Picture` object.

The new code

The only code in Listing 4 (p. 876) that is new to this module is the call to the `setClip` method.

The `setClip` method is defined in the `Graphics` class and inherited into the `Graphics2D` class.

(Among other things, that means that it wasn't necessary for me to cast the `Graphics` object to type `Graphics2D` in Listing 4 (p. 876) .)

The setClip method

There are a couple of overloaded versions of the `setClip` method. The one used in Listing 4 (p. 876) requires an incoming parameter of the interface type `Shape` .

The Shape interface

Briefly, Sun tells us that the `Shape` interface "provides definitions for objects that represent some form of geometric shape."

There are several dozen classes that implement the `Shape` interface, one of which is the class named `Ellipse2D.Double` . Therefore, the object of that type that is instantiated in Listing 4 (p. 876) satisfies the type requirement for being passed to the `setClip` method.

Behavior of the setClip method

With regard to the behavior of the `setClip` method, Sun tells us that the method

"Sets the current clipping area to an arbitrary clip shape."

What is the significance of the clipping area?

The closest answer that I can find for that question is the following statement in Sun's description of the `Graphics` class:

"All rendering operations modify only pixels which lie within the area bounded by the current clip, which is specified by a `Shape` in user space and is controlled by the program using the `Graphics` object."

In other words...

The *clipping area* is analogous to the *current clip* . In this case, the position and shape of the current clip is the position and shape of the ellipse.

When the image is later drawn on the red `Picture` object, only those pixels within the ellipse are modified to show the image. The remaining pixels retain their original color, which was set to red early in Listing 4 (p. 876) .

End of discussion

That concludes my explanation of this program. You will find the methods that I didn't discuss in Listing 5 (p. 879) near the end of the module.

3.3.30.5 Run the program

I encourage you to copy the code from Listing 5 (p. 879) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

3.3.32.3 Preview

In this module, you will learn how to do a linear merge on two pictures based on the distance of each pixel from the left side of the picture.

Program specifications

Write a program named **Prob05** that uses the class definition shown in Listing 1 (p. 892) and Ericson's media library along with the image files named **Prob05a.jpg** and **Prob05b.jpg** (see Figure 1 (p. 889) and Figure 2 (p. 890)) to produce the graphic output image shown in Figure 3 (p. 890) .

Required output text

In addition to the output image mentioned above, your program must display your name and the other line of text shown in Figure 4 (p. 891) on the command-line screen.

Figure 4 - Required output text.

```

Table 3.352

3.3.32.4 Discussion and sample code

This program does a linear merge on two pictures based on the distance of each pixel from the left side of the picture. The program also adds a sun with a gradient and the student's name to the picture.

Will discuss in fragments

I will discuss and explain this program in fragments. A complete listing of the program is provided in Listing 6 (p. 896) near the end of the module.

The driver class named Prob05

The driver class containing the `main` method is shown in Listing 1 (p. 892) .

Listing 1 - The driver class named Prob05.

```

    public class Prob05{
    public static void main(String[] args){
        new Prob05Runner().run();
    }//end main method
} //end class Prob05

```

Table 3.353

The code in Listing 1 (p. 892) shouldn't require an explanation at this stage in the course.

Beginning of the class named Prob05Runner

The class named **Prob05Runner** begins in Listing 2 (p. 892) .

Listing 2 - Beginning of the class named Prob05Runner.

```

    class Prob05Runner{
    public Prob05Runner(){
        System.out.println("Display your name here.");
    } //end constructor

```

Table 3.354

As with Listing 1 (p. 892) , the code in Listing 2 (p. 892) shouldn't require an explanation.

The run method of the Prob05Runner class

Listing 1 (p. 892) calls the **run** method on an object of the **Prob05Runner** class. The **run** method is shown in its entirety in Listing 3 (p. 892) .

Listing 3 - The run method of the Prob05Runner class.

```

    public void run(){
    Picture penguin = new Picture("Prob05a.jpg");
    Picture hare = new Picture("Prob05b.jpg");
    merge(hare,penguin);
    hare = crop(hare,6,58,330,252);
    hare.addMessage("Display your name here.",10,20);
    drawSun(hare);
    hare.show();
    System.out.println(hare);
    } //end run

```

Table 3.355

The only thing in Listing 3 (p. 892) that I haven't explained in earlier modules is the call to the **merge** method, so I will limit my discussion to that method.

The merge method

The **merge** method is used to merge the image in Figure 1 (p. 889) with the image in Figure 2 (p. 890) to produce the image shown in Figure 3 (p. 890) .

(Note, however, that the merged image was cropped to eliminate the buttons at the top of Figure 1 (p. 889) and Figure 2 (p. 890) before displaying it in Figure 3 (p. 890) .)

A linear merge

The **merge** method does a linear merge on two pictures based on the distance of each pixel from the left side of the picture.

The method assumes that both pictures have the same dimensions.

Beginning of the merge method

The **merge** method begins in Listing 4 (p. 893) .

Listing 4 - Beginning of the merge method.

```
private void merge(Picture left,Picture right){
int width = left.getWidth();
int height = left.getHeight();

double scaleL = 0;
double scaleR = 0;
int redL = 0;
int greenL = 0;
int blueL = 0;
int redR = 0;
int greenR = 0;
int blueR = 0;
Pixel pixelL = null;
Pixel pixelR = null;
```

Table 3.356

The code in Listing 4 (p. 893) simply declares and initializes a large number of working variables.

Do the merge

The merge is accomplished in the nested **for** loop in Listing 5 (p. 894) .

Listing 5 - Do the merge.

```

    for(int row = 0;row < height;row++){
for(int col = 0;col < width;col++){
    scaleR = (double)col/width;
    scaleL = 1.0 - scaleR;
    pixelL = left.getPixel(col,row);
    pixelR = right.getPixel(col,row);

    redL = pixelL.getColor().getRed();
    greenL = pixelL.getColor().getGreen();
    blueL = pixelL.getColor().getBlue();

    redR = pixelR.getColor().getRed();
    greenR = pixelR.getColor().getGreen();
    blueR = pixelR.getColor().getBlue();

    redL = (int)(redL*scaleL + redR*scaleR);
    greenL = (int)(greenL*scaleL + greenR*scaleR);
    blueL = (int)(blueL*scaleL + blueR*scaleR);

    pixelL.setColor(new Color(redL,greenL,blueL));
} //end inner loop
} //end outer loop
} //end merge

```

Table 3.357**Difficult to explain**

Although the code in Listing 5 (p. 894) is long, tedious, and ugly, it isn't complicated. However, it is somewhat difficult to explain in words.

Two scale factors

The body of the **for** loop begins by computing a pair of scale factors named **scaleR** and **scaleL**. The factor named **scaleR** has a maximum value of 1.0 and is directly proportional to the distance of the current pixel from the left edge of the picture.

The factor named **scaleL** also has a maximum value of 1.0 and is inversely proportional to the distance of the pixel from the left edge.

Get and save color components

The red, green, and blue values for the same pixel location in each of the pictures are obtained and saved.

Compute a new set of color values

A new set of red, green, and blue color values are computed as the sum of scaled versions of the pixel colors from the rabbit image pixel and the penguin image pixel.

The nature of the scaling

The scaling is such that the pixel colors from the rabbit image contribute most heavily to output pixels to the left of center and pixel colors from the penguin image contribute most heavily to output pixels to the right of center.

You can see the effect of this scaling algorithm in Figure 3 (p. 890).

The pixels in the horizontal center

The pixels along a vertical line at the center of the output image contain equal contributions of colors from both images.

End of discussion

That concludes the explanation of the code in this program.

You can view the **drawSun** and **crop** methods in Listing 6 (p. 896) near the end of the module.

3.4.1.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming in general and the Java Collections framework in particular.

The purpose of this module is to introduce you to the Java Collections Framework. Once you learn how to use the framework, it is unlikely that you will need to reinvent common data structures, search algorithms, or sorting algorithms again, because those capabilities are neatly packaged within the framework.

In addition to studying these modules, I strongly recommend that you study the Collections Trail ⁴¹⁰ in Oracle's Java Tutorials ⁴¹¹. The modules in this collection are intended to supplement and not to replace those tutorials.

3.4.1.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the listings while you are reading about them.

3.4.1.3 Preview

This module provides a brief introduction to the use of the *Java Collections Framework* . The framework is designed to encourage you to reuse rather than to reinvent collections and maps.

A collection represents a group of objects, known as its elements. Some collections allow duplicate elements while others do not. Some collections are ordered and others are not. (*Maps will be discussed in future modules.*)

The *Collections Framework* is defined by a set of interfaces and associated contracts, and provides concrete implementations of the interfaces for the most common data structures. In addition, the framework also provides several abstract implementations, which are designed to make it easier for you to create new and different implementations while still maintaining the structural polymorphic integrity of the framework.

3.4.1.4 Generics

The code in this series of modules is written with no thought given to Generics ⁴¹² . As a result, if you copy and compile the code, you will probably get warnings about *unchecked or unsafe operations* .

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.1.5 Introduction

3.4.1.5.1 A quiz

Let's begin with a little quiz to establish your baseline knowledge of the Collections Framework. Take a look at the program in Listing 6 (p. 916) near the end of this module. Which of the following is the output produced by that program?

- A. Compiler Error
- B. Runtime Error
- C. 44321
- D. 12344
- E. 1234
- F. None of the above.

If your answer was **1234** (*and it wasn't a guess*) then you may already know quite a lot about the use of the Collections Framework. If not, keep reading to begin learning about the framework.

3.4.1.5.2 Elements of the Framework are easy to use

This simple introductory program is not intended to do anything useful. Instead, it was designed to illustrate several important features of the framework, including the ease with which elements of the framework can be reused in your programs.

3.4.1.5.3 Don't reinvent the wheel

As many of you already know, I am a college professor. I specialize in teaching OOP using Java. In the past, many college courses in Data Structures (*often referred to as CS2 courses*) have emphasized the concept of *reinventing the wheel* . Students were required to learn how to reinvent a variety of complex data structures in order to successfully complete the course.

Hopefully, with the conversion of these CS2 courses to Java OOP, the emphasis will change to *reuse* instead of *reinvent* .

⁴¹²<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

3.4.1.5.4 Collections Framework encourages reuse

The Java Collections Framework is designed to encourage programmers to reuse existing interfaces and classes instead of inventing new ones. In the event that it is necessary to invent a new class or interface, the programmer is encouraged to integrate it into the framework in a polymorphic manner.

3.4.1.6 Sample program

I am going to provide a brief discussion of the sample program (shown in Listing 6 (p. 916)) in this module. Later, I will provide more detailed discussions of many of the features used in that program.

3.4.1.7 Interesting code fragments

I will break this program down and discuss it in fragments.

3.4.1.7.1 An object of the TreeSet class

The code fragment in Listing 1 (p. 909) instantiates an object of the **TreeSet** class and stores the object's reference in a reference variable of type **Collection** named **ref** .

Listing 1 . A new object of the TreeSet class.

```
class Worker{
public void doIt(){
    Collection ref = new TreeSet();
}
```

Table 3.360

3.4.1.7.2 Collection is an interface

The **TreeSet** class implements the **SortedSet** interface, which extends the **Set** interface, which in turn extends the **Collection** interface. Thus, a **TreeSet** object is a **Collection** . Therefore, a reference to a **TreeSet** object can be stored in a reference variable of type **Collection** , and can be treated as the generic type **Collection** .

3.4.1.7.3 What is a TreeSet object?

Among other things, in CS2 courses, we worry about the time and memory cost of a collection. According to Sun, the **TreeSet** class guarantees that the sorted set will be in ascending element order, and provides guaranteed $\log(n)$ time cost for the basic operations (*add* , *remove* and *contains*).

3.4.1.7.3.1 What does ascending element order mean?

Again, according to Sun, the elements will be sorted according to the *natural order* of the elements (see *the Comparable* ⁴¹³ *interface*) or by a comparator (see *the Comparator* ⁴¹⁴ *interface*) provided at the time the set is created. This depends on which overloaded constructor is used. I will have more to say about these alternatives in a future module.

⁴¹³<http://cnx.org/contents/L3qgZmWm>

⁴¹⁴http://cnx.org/contents/5_Rd_R2l

3.4.1.7.3.2 What does $\log(n)$ time cost mean?

I'm not going to try to explain the details of $\log(n)$ time cost here. Suffice it to say that the `add`, `remove`, and `contains` methods execute very fast. (*I will have more to say about this in a future module.*)

3.4.1.7.3.3 A `TreeSet` object is a `Set`

An object of the `TreeSet` class also is a `Set`. One of the characteristics of a Java `Set` (an object that implements the `Set` interface) is that it can contain no duplicate elements. Therefore, a `TreeSet` object can contain no duplicate elements. If the `add` method of a `TreeSet` object is called in an attempt to add a duplicate element, the element will not be added.

3.4.1.7.3.4 A `TreeSet` object is a `SortedSet`

The `TreeSet` class also implements the `SortedSet` interface. This guarantees that the contents of a `TreeSet` object will be in ascending element order, regardless of the order in which the elements are added. (*In a future module, I will discuss how comparisons are made to enforce the ordering of the elements.*)

3.4.1.7.3.5 A `TreeSet` object is a `Collection`

Because an object of the `TreeSet` class is a `Collection`, a reference to such an object can be passed to any method that requires an incoming parameter of type `Collection`. The receiving method can call any method on that reference that is declared in the `Collection` interface. (*I will discuss such methods in detail in future modules.*)

3.4.1.7.4 Populate the `Collection`

The statement in Listing 2 (p. 910) passes the `TreeSet` object's reference to a method named `fillIt`, which is a static method of the `Populator` class. (*The `Populator` class is a class of my own design whose only purpose is to illustrate the polymorphic behavior achieved using the Collections Framework.*) The behavior of this method is to add elements to the incoming `Collection` object without regard for the actual type of the object (*the class from which the object was instantiated*).

Listing 2 . Populate the collection.
<code>Populator.fillIt(ref);</code>

Table 3.361

At this point, I am going to discuss the `fillIt` method of the `Populator` class called in Listing 2 (p. 910). The entire class definition of the `Populator` class, including the `fillIt` method, is shown in Listing 3 (p. 910).

Listing 3 . The <code>Populator</code> class.
<i>continued on next page</i>

```
class Populator{
public static void fillIt(Collection ref){
    ref.add(new Integer(4));
    ref.add(new Integer(4));
    ref.add(new Integer(3));
    ref.add(new Integer(2));
    ref.add(new Integer(1));
} //end fillIt()
} //end class populator
```

Table 3.362

3.4.1.7.4.1 Don't know, don't care

As you can see in the above fragment, the `fillIt` method receives the reference to the `TreeSet` object as type `Collection`. This method doesn't know, and doesn't care, what the actual type of the object is. All it cares about is that the object *is a* `Collection` object. (*Otherwise, the object's reference couldn't be passed in as a parameter. A type mismatch would occur.*)

Because the incoming parameter is a reference to a `Collection` object, the `fillIt` method can call the `add` method on the object with confidence that the behavior of the `add` method will be appropriate for the specific type of object involved. (*For example, the behavior of the add method for an object of the `TreeSet` class will probably be different from the behavior of the add method for an object of some other class that implements the `Collection` interface.*)

3.4.1.7.4.2 Polymorphism in action

The great thing about polymorphic behavior is that the author of the `fillIt` method doesn't need to be concerned about the implementation details of the `add` method.

3.4.1.7.4.3 Add five elements with some duplicates

The code in the `fillIt` method adds five elements to the object. Each element is a reference to a new object of type `Integer`. Two of the objects encapsulate the `int` value 4, and thus are duplicates.

The `int` values encapsulated in the `Integer` objects are not in ascending order. Rather, they are added to the object in descending order. (*They could be added in any order and the end result would be the same.*)

3.4.1.7.4.4 Filter out the duplicates

The `add` method for the `TreeSet` object filters out the duplicate element in order to satisfy the contract of the `Collection` interface.

3.4.1.7.4.5 Notification of duplicates

In this case, the author didn't care what happens in the case of duplicate elements. If the author of the `fillIt` method does care what happens in the case of duplicates, she can find out when an object is a duplicate.

According to the contract of the `Collection` interface, the `add` method must return `true` if the call to the method modifies the contents of the object and must return `false` if the collection does not permit duplicates and the collection already contains the specified element.

3.4.1.7.4.6 Sort the elements

Even though the elements are passed to the `add` method in descending order (*or could be passed in any other order*), they are stored and maintained in the `TreeSet` object in such a way that they can later be accessed in ascending order.

3.4.1.7.4.7 The `TreeSet` object is now populated

When the `fillIt` method returns, the `TreeSet` object contains four (*not five*) elements with no duplicates. Each element is a reference to an object of type `Integer`. Those references are maintained in such a way as to make them accessible in ascending order, based on the `int` values encapsulated in each of the `Integer` objects.

3.4.1.7.5 Get an `Iterator` object

Returning now to the `doIt` method in the `Worker` class that was called in Listing 1 (p. 909), the statement in Listing 4 (p. 912) calls the `iterator` method on the `TreeSet` object's reference that is stored in the reference variable of type `Collection`.

Listing 4 . Get an <code>Iterator</code> object.
<pre>Iterator iter = ref.iterator();</pre>

Table 3.363

The call to the `iterator` method on any `Collection` object returns an instance of a class that implements the `Iterator` interface. The `Iterator` object can be used to traverse the collection, gaining access to each element in order. (*The concept of in order means different things for different kinds of collections. For a collection instantiated from the `TreeSet` class, in order means in ascending order.*)

3.4.1.7.5.1 Again, don't know, don't care

Again, the author of the method that uses the `Collection` object doesn't need to know or care about the internal implementation of the collection, or the implementation of the methods of the `Iterator` object. They simply do what they do, and can be used for their intended purpose.

3.4.1.7.5.2 An `Iterator` object acts as a doorkeeper

The `Iterator` interface declares three methods:

- `hasNext()`
- `next()`
- `remove()`

You might say that an `Iterator` object acts as a doorkeeper for the collection object that it represents, providing access to the contents of the collection in a very specific manner.

3.4.1.7.5.3 Traverse the collection

The code fragment in Listing 5 (p. 913) below shows how the first two of the above methods can be used to

- Traverse the collection, accessing each of the object's elements in succession.
- Display the value encapsulated in the object referred to by each element.

As mentioned earlier, when the collection is an object instantiated from the `TreeSet` class, access to the elements is provided in ascending order.

Listing 5 . Traverse the collection.

```

while(iter.hasNext()){

3.4.1.7.5.4 Four elements with no duplicates

At this point, the `TreeSet` object contains four elements, with no duplicates. Each of the elements is a reference to an object of type `Integer` . The code in the loop in Listing 5 (p. 913) causes each of those elements to be accessed and displayed in ascending order. This causes the following text to appear on the screen:

3.4.1.7.6 An editorial opinion

In my opinion, this is the kind of knowledge that a computer science student in a modern data structures course should be learning. This is a far departure from courses of the past where CS2 students were required to memorize the intricate details of how to implement various data structures.

3.4.1.7.6.1 What kind of knowledge is needed?

Does an architect need to understand the detailed inner workings of an air conditioning compressor to design a cooling system into a building? Of course not!

However, the architect does need to know the tradeoffs among the available cooling systems in terms of initial cost, operating cost, size, efficiency, etc.

Does an audio technician need to understand the detailed inner workings of an electronic audio equalizer in order to construct an integrated audio system? Absolutely not! If that were a requirement, there would likely be very few audio systems in existence.

However, the audio technician does need to understand the tradeoffs among the various available audio equalizers.

3.4.1.7.6.2 The same concept applies to software design

Does an OOP software designer need to know the detailed inner workings of the various kinds of collection objects in order to use them effectively? No!

However, the software designer does need to know the tradeoffs among the various types of collection objects in terms of their operational behavior.

Modern CS2 students should be learning about the performance and operational differences among the different types of collections, and how to use available frameworks to create and use those collections. They should not be wasting their time learning how to reinvent them. They have more important ways to spend their time, and they have more important things to learn.

3.4.1.7.6.3 An analogy

Frankly, I don't care how the programmers at Sun implemented the **TreeSet** class, so long as the behavior of objects instantiated from that class meets the published specifications.

As an analogy, I also don't care how they implemented the **Random** class, so long as objects instantiated from the **Random** class provide the pseudo random values that I need in my programs.

I see no conceptual differences between the **TreeSet** class and the **Random** class from a software reuse viewpoint.

- I can instantiate an object of the **Random** class to produce pseudo random values, without caring how those values are actually generated. However, if I am working in cryptography, I might need to know how many such values can be generated before the sequence repeats.
- I can use any of the thirty or so methods of the **Math** class to produce a variety of complex mathematical values without caring about how those values are actually produced. However, since many of those values are approximations, I might need to know something about the quality of the approximation.
- I can instantiate an object of the **TreeSet** class to create a collection object that guarantees that the sorted set will be in ascending element order, and provide $\log(n)$ time cost for the basic operations of *add*, *remove*, and *contains*. As long as I know that, I have very little need to know exactly how the collection object is implemented.

3.4.1.7.6.4 Its time to reinvent the CS2 curriculum

Having worked for 32 years in high-tech industry before becoming a college professor, I'm confident that the future employers of most students share my opinion on this. I don't know of any employer who wants their programmers to spend time and dollars reinventing the classical data structures. What those employers are looking for is a staff of programmers who understand the tradeoffs among the data structures, and when it is appropriate to use each of the different structures.

It is time to reinvent the curriculum in CS2 courses by

- Encouraging the understanding of techniques for software reuse.
- Teaching when, why, and how each of the different structures should be used.
- Discouraging the reinvention of those structures.

3.4.1.8 Run the program

Okay, I will step down from my soapbox. I encourage you to copy the code from Listing 6 (p. 916) and paste it into your text editor. Then compile and execute it.

Run the program and observe the results. Experiment with the code. Make changes, run the program again, and observe the results of your changes. Make certain that you can explain why your changes behave as they do.

3.4.1.9 Summary

In this module, I have provided a brief introduction to the use of the *Java Collections Framework*. The framework is designed to encourage you to reuse rather than to reinvent collections and maps (*I will have more to say about maps in a future module*).

A collection represents a group of objects, known as its elements.

While some collections allow duplicate elements, others do not. Some collections are ordered and others are not ordered.

The *Collections Framework* is defined by a set of interfaces and associated contracts. The framework provides concrete implementations of the interfaces (*classes*) for the most common data structures. In addition, the framework also provides several abstract implementations, which are designed to make it easier for you to create new and different concrete implementations.

The `TreeSet` class is a concrete implementation of the `SortedSet` interface. The `SortedSet` interface extends `Set`, which extends `Collection`. Thus, a `TreeSet` object is a `SortedSet`. Also it is a `Set`, and it is a `Collection`.

The `TreeSet` class guarantees that the sorted set will be in ascending element order, and provides guaranteed $\log(n)$ time cost for the basic operations (*add*, *remove* and *contains*).

`TreeSet` objects can be treated as the generic type `Collection`. Methods declared in the `Collection` interface can be called on a `Collection` object without regard for the actual class from which the object was instantiated. (*This is polymorphic behavior.*)

When such methods are called, the author of the program can have confidence that the behavior of the method will be appropriate for an object of the class from which the object was instantiated. In my opinion, this is the true essence of object-oriented behavior.

3.4.1.10 What's next ?

This is the first module in a miniseries on the *Collection Framework*. Subsequent modules will teach you how to use the framework for creating and using various types of collections and maps.

Once you learn how to use the framework, it is unlikely that you will need to reinvent classical data structures, search algorithms, or sorting algorithms, because those capabilities are neatly packaged within the framework.

Back to Question 22 (p. 920)

3.4.2.5.5 Answer 21

False. The concept of **in order** means different things for different **Collection** objects. For a collection instantiated from the **TreeSet** class, for example, **in order** means in ascending order. However, that may not be the case for a different object instantiated from a class that implements the **Collection** interface.

False. In Listing 1 (p. 918) , when the **fillIt** method returns, the **TreeSet** object contains four (*not five*) elements with no duplicates. Each element is a reference to an object of type **Integer** . Those references are maintained in such a way as to make them accessible in **ascending** order, based on the **int** values encapsulated in each of the **Integer** objects.

3.4.2.5.10 Answer 16

True. For example, the behavior of the **add** method for an object of the **TreeSet** class will probably be different from the behavior of the **add** method for an object of some other class that implements the **Collection** interface.

Back to Question 16 (p. 920)

3.4.2.5.11 Answer 15

False. The **fillIt** method receives the reference as type **Collection** . This method doesn't know, and doesn't care, what the actual type of the object is. All it cares about is that the object *is a* **Collection** object. (*Otherwise, the object's reference couldn't be passed in as a parameter. A type mismatch would occur.*) A **TreeSet** object is a **Collection** because the **TreeSet** class implements the **Collection** interface. A **Button** object is not a **Collection** because the **Button** class does not implement the **Collection** interface.

3.4.2.5.16 Answer 10

False. An object of the **TreeSet** class also *is a* **Set** . One of the characteristics of a Java **Set** (*an object that implements the Set interface*) is that it can contain no duplicate elements. Therefore, a **TreeSet** object can contain **no** duplicate elements.

3.4.3.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java Collections framework in particular.

The purpose of this module is to explain some of the details surrounding the use of a Java collection for creating data structures. The module also discusses the interfaces and some of the concrete implementations in the Java Collections Framework.

In addition to studying these modules, I strongly recommend that you study the Collections Trail ⁴²² in Oracle's Java Tutorials ⁴²³ . The modules in this collection are intended to supplement and not to replace those tutorials.

3.4.3.3 Preview

Collection is not only the name of a Java interface, it is also the term given to an object that groups multiple elements into a single unit.

I will discuss the advantages of passing collections between methods as type **Collection** .

I will summarize the core interfaces in the *Collections Framework* and show you how they are related.

I will very briefly discuss some of the concrete implementations of the interfaces that are provided by the framework.

And finally, I will introduce you to the three kinds of things that are part of a collections framework.

3.4.3.4 Generics

The code in this series of modules is written with no thought given to Generics ⁴²⁴ . As a result, if you copy and compile the code, you will probably get warnings about *unchecked or unsafe operations* .

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.3.5 Discussion

3.4.3.5.1 What is a collection?

Just to see if you are awake today, let's start with a little quiz.

What is a collection insofar as Java programming is concerned?

- A. Something they gather in plates at church.
- B. An object that groups multiple elements into a single unit.
- C. The name of a Java interface.
- D. None of the above.

If you answered A, you are probably reading an article on the wrong website by mistake. If you answered *Both B and C*, then you are off to a good start on this module.

Collection is the name of a Java interface. This interface is an integral part of the *Java Collections Framework*. **Collection** is one of two top-level interfaces in the framework. The other top-level interface in the framework is named **Map**.

According to The Java Tutorial from Oracle, a collection (*sometimes called a container*) is also an object that groups multiple elements into a single unit.

Typical collection objects might contain information about employees in the company telephone book, all the purchase orders issued during the past year, or the transactions occurring in a person's checking account.

3.4.3.5.2 Slightly different terminology

Note that this terminology may be somewhat different from what you are accustomed to. For example, if you speak of your *coin collection*, you are probably speaking about the actual coins rather than the container that holds the coins.

This is an important distinction. The usage of the term *collection* in the *Collections Framework* usually refers to the container and not to the contents of the container. In the framework, the contents are usually referred to as the *elements*.

3.4.3.5.3 Store references rather than objects

The collections in the framework always store references to objects, rather than storing the objects themselves. One consequence of this is that primitive values cannot be stored in a collection without first encapsulating them in an object. (*Standard wrapper classes are provided for encapsulating all primitive types.*)

3.4.3.5.4 Stored as type Object

Furthermore, the references are always stored as type **Object**. Prior to Java version 1.5, when you retrieved an element from a collection, you frequently needed to downcast it before you could gain access to the members of the object to which the reference refers. Version 1.5 introduced Generics⁴²⁵ into the Java programming environment, which eliminated that requirement, (*provided that you use the more complex syntax required by Generics*).

3.4.3.5.5 Moving data among methods

In addition to their use for storing, retrieving, and manipulating data, collections are also used to move data among methods.

One of the primary advantages of the Collections Framework is the ability to pass a collection to a method as the generic interface type **Collection**. The receiving method doesn't need to know the actual type of the object referred to by the incoming reference in order to call its methods.

⁴²⁵<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

3.4.3.5.6 Polymorphic behavior

The receiving method can call (*on the reference to the Collection object*) any of the methods declared in the **Collection** interface, with confidence that the behavior of the method will be appropriate for the actual type of **Collection** object involved. (*That is polymorphic behavior.*)

3.4.3.5.7 Core collection interfaces

If you have been working with the framework, you might be inclined to think that all of the interfaces in the following list are members of the *core collection interfaces*.

- Collection
- Set
- List
- Queue
- Deque
- SortedSet
- Map
- SortedMap
- Iterator

However, that is not the case.

While the **Iterator** interface is heavily used in conjunction with collections, according to The Java Tutorial from Oracle, it is not one of the *core collection interfaces*.

The core collection interfaces identified by the Oracle book are shown below, with indentation showing the parent-child relationships among the interfaces.

- **Collection**
 - Set
 - * SortedSet
 - List
 - Queue
 - Deque
- **Map**
 - SortedMap

As you can see, as mentioned earlier, **Collection** and **Map** are the two top-level interfaces.

You should probably commit the above list of interfaces and their relationships to memory. You might find that helpful when navigating the Oracle documentation.

3.4.3.5.8 Concrete implementations

In addition to interfaces, the framework provides several concrete implementations of the interfaces defined in the framework. (*A concrete implementation is a class that implements one or more of the interfaces.*)

Are you still awake? If so, see if you can answer the following question.

True or False? Each of the following classes provides an implementation of one of the interfaces that make up the Java Collections Framework. If False, which items don't belong in the list.

- AbstractSet
- AbstractList
- AbstractMap
- HashSet

- TreeSet
- LinkedList
- Vector
- ArrayList
- HashMap
- Hashtable
- WeakHashMap
- TreeMap
- Iterator
- Attributes
- RenderingHints

Hopefully your answer was False, but even so, that isn't the complete answer.

3.4.3.5.9 Iterator is not a class

To begin with, **Iterator** is not a class. I told you that a couple of paragraphs back. It is an interface. Therefore, it has no place in the above list of classes.

3.4.3.5.10 What about Attributes and RenderingHints?

You may also have wondered if the classes named **Attributes** and **RenderingHints** belong on the list. Note that I didn't restrict the above list to only those classes that might be considered part of the framework, so this was sort of a trick question. (*Of course you could have looked them up in the Oracle documentation just like I did.*)

While these two classes are not really a part of the core Java Collections Framework, they do implement interfaces that are part of the framework.

The **RenderingHints** class implements the **Map** interface, and is used in conjunction with the **Graphics2D** class. The **Attributes** class also implements the **Map** interface,

3.4.3.5.11 What is a Collections Framework?

According to The Java Tutorial from Oracle, "*A collections framework is a unified architecture for representing and manipulating collections. All collections frameworks contain three things.*"

Those three things are:

- Interfaces
- Implementations
- Algorithms

This is probably a good place to close off the discussion for this module. The next module will pick up at this point and provide a more in-depth discussion of the interfaces, implementations, and algorithms that make up the framework.

3.4.3.6 Summary

I started out by telling you that a collection is not only the name of a Java interface (*Collection*) but is also an object that groups multiple elements into a single unit.

Java **Collection** objects don't store objects or primitive values directly. Rather, they store references to objects. Further, all such references are stored as the type **Object**. However, the use of the **Generics** syntax can eliminate the need to downcast the reference in order to gain access to the members of the object to which it refers. (*Generics also provide other useful properties as well.*)

If you need to store primitive values in a collection, you will first need to wrap those values in appropriate objects. Standard wrapper classes are provided for all the primitive types.

Collections are not only useful for storing and retrieving data, they are also useful for moving data among methods.

Because a collection can be passed to a method as type **Collection** , all of the methods declared in the **Collection** interface can be called on the incoming reference in a polymorphic manner.

In addition to the interfaces defined in the Collections Framework, the framework also provides various concrete implementations of the interfaces for many of the commonly-used data structures. This makes it possible for you to conveniently use the framework without the requirement to define new **Collection** classes.

There are eight core interfaces in the Collections Framework. Although the **Iterator** interface is often used with collections, it is not one of the core interfaces.

I ended the module by telling you that there are basically three things in a collections framework: *interfaces* , *implementations* , and *algorithms* . I will have more to say about this in a future module.

3.4.5.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java Collections framework in particular.

There are eight core interfaces in the *Collections Framework*. Each interface declares several methods and provides a contract that applies to each declared method. The method declarations and their associated contracts specify the general behavior of matching methods in the classes that implement the interfaces.

The purpose of this module is to provide a brief explanation of those interfaces.

In addition to studying these modules, I strongly recommend that you study the Collections Trail ⁴³³ in Oracle's Java Tutorials ⁴³⁴. The modules in this collection are intended to supplement and not to replace those tutorials.

3.4.5.3 Preview

At least three things are included in a collections framework:

- interfaces
- implementations
- algorithms

This module will discuss the purpose of the interfaces in the Collections Framework. Future modules will discuss implementations and algorithms.

3.4.5.4 Introduction

In an earlier module, we learned that the Collections Framework contains eight core interfaces with the parent-child relationships **shown below** :

- **Collection**

⁴³³<http://docs.oracle.com/javase/tutorial/collections/index.html>

⁴³⁴<http://docs.oracle.com/javase/tutorial/index.html>

- Set
 - * SortedSet
- List
- Queue
- Deque
- **Map**
 - SortedMap

3.4.5.5 Generics

The code in this series of modules is written with no thought given to Generics ⁴³⁵ . As a result, if you copy and compile the code, you will probably get warnings about *unchecked or unsafe operations* .

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.5.6 Discussion

3.4.5.6.1 Purpose of framework interfaces

A *collection* is an object of some type, and that type is defined in a generic sense by one or more interfaces that make up the Collections Framework.

3.4.5.6.2 What is a data type?

All data types specify the operations that can be performed on an entity of that type. (*Data types also specify the kinds of data that can be stored in an entity of that type, but that is not germane to this discussion.*)

3.4.5.6.3 Interface is a type

An object in Java can often be considered to be of several different types. One of those types is determined by any interfaces implemented by the class from which the object was instantiated. Framework collection objects in Java are instantiated from classes that implement the core interfaces of the Collections Framework.

Thus, a Java interface in the Collections Framework specifies the type of such an object, and provides a generic representation of the operations that apply across different implementations of the interface.

3.4.5.6.4 Collection interface declares several methods

The **Collection** interface declares several methods. This is not unusual. From a technical standpoint, all interfaces declare none, one, or more methods. Most interfaces declare multiple methods. (*Interfaces can also declare constants, but that is not germane to this discussion.*)

In general, there is no technical requirement for a specification of the behavior of the interface methods when implemented in a class. In fact, because a method that is declared in an interface is abstract, it specifically refrains from defining the behavior of the method. The interface definition simply declares the interfaces for all the methods that it declares.

We have now arrived at one of the differences that distinguish the Collections Framework from *"just a bunch of interfaces."* That difference is *contracts* .

⁴³⁵<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

3.4.5.6.5 An extra step

The Oracle documentation for the **Collection** interface goes a step beyond the minimum technical requirements for an interface. The documentation describes the general behavior that *must be exhibited* by each of the methods belonging to an object instantiated from a class that implements the **Collection** interface. This is sometimes referred to as a *contract* .

Therefore, if you define a class that implements the **Collection** interface in a manner consistent with the *Collections Framework* , it is important that you make certain that each of your methods behaves as described in the Oracle documentation. In other words, you must be careful to comply with the contract defined for those methods. If you don't do that, a user can't rely on objects instantiated from your class to exhibit proper behavior.

3.4.5.6.6 The add method in Collection

For example, the **Collection** interface declares a method named **add** that receives an incoming reference of a generic type (see *Generics* ⁴³⁶) and returns a **boolean** . Here is some text from the Oracle documentation describing the required behavior (*contract*) of the **add** method for any class that implements the **Collection** interface.

"Ensures that this collection contains the specified element (optional operation). Returns true if this collection changed as a result of the call. (Returns false if this collection does not permit duplicates and already contains the specified element.)

Collections that support this operation may place limitations on what elements may be added to this collection. In particular, some collections will refuse to add null elements, and others will impose restrictions on the type of elements that may be added.

Collection classes should clearly specify in their documentation any restrictions on what elements may be added. If a collection refuses to add a particular element for any reason other than that it already contains the element, it must throw an exception (rather than returning false). This preserves the invariant that a collection always contains the specified element after this call returns."

As you can see, the behavior is defined in a very general way. There is no indication as to how that behavior is to be achieved.

3.4.5.6.7 The add method in Set

As you can see from the list above (p. 937) , the **Set** interface extends the **Collection** interface. In keeping with the general form of object-oriented design, **Set** is more specialized than **Collection** . Therefore, **Set** makes the contract for the **add** method more specific for objects of type **Set** . Here is some text from the Oracle documentation describing the contract of the **add** method for any class that implements the **Set** interface.

*"Adds the specified element to this set if it is not already present (optional operation). More formally, adds the specified element *e* to this set if the set contains no element *e2* such that (*e*==null ? *e2*==null : *e.equals(e2)*).*

If this set already contains the element, the call leaves the set unchanged and returns false. In combination with the restriction on constructors, this ensures that sets never contain duplicate elements.

*The stipulation above does not imply that sets must accept all elements; sets may refuse to add any particular element, including null, and throw an exception, as described in the specification for *Collection.add*. Individual set implementations should clearly document any restrictions on the elements that they may contain."*

3.4.5.6.8 How do the contracts differ?

The contract for the **add** method, as declared in the **Collection** interface, does not prohibit duplicate elements, but does make the provision for interfaces that extend **Collection** to prohibit duplicate elements.

⁴³⁶<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

The contract for the `add` method in the `Set` interface does prohibit duplicate elements.

3.4.5.6.9 What about the List interface?

Here is some text from the Oracle documentation describing the contract of the `add` method for any class that implements the `List` interface.

"Appends the specified element to the end of this list (optional operation).

Lists that support this operation may place limitations on what elements may be added to this list. In particular, some lists will refuse to add null elements, and others will impose restrictions on the type of elements that may be added. List classes should clearly specify in their documentation any restrictions on what elements may be added."

As you can see, the contract for the `add` method declared in the `List` interface, (which extends `Collection`), does not prohibit duplicate elements. However, it does have some other requirements that don't apply to `Set` objects. For example, it must add new elements at the end of the list.

3.4.5.6.10 A major difference

This is one of the major differences between lists and sets in the Java Collection Framework. Both `List` objects and `Set` objects are collections, because both of the interfaces extend the `Collection` interface. However, the `Set` interface contract prohibits duplicate elements while the `List` interface contract does not prohibit duplicate elements.

3.4.5.6.11 Designing a framework

In theory, it should be possible (*but perhaps not very practical*) to define a framework consisting solely of interface definitions and associated contracts for methods and algorithms. Then each user could implement the interfaces however they see fit, provided that they comply with the contracts. (*This might not be very practical, however, because every user of the framework would then be required to implement the interfaces, which would entail a lot of work.*)

3.4.5.6.12 Concrete implementations

Fortunately, Oracle didn't stop work after defining the interfaces and contracts for the Java Collections Framework. Rather, they also provided us with several useful classes that implement the interfaces in the framework. Thus, we can instantiate and use objects of those classes immediately without having to define them ourselves. Here is a list of some of the concrete implementation classes in the Java Collections Framework:

- `HashSet`
- `TreeSet`
- `LinkedList`
- `Vector`
- `ArrayList`
- `HashMap`
- `Hashtable`
- `WeakHashMap`
- `TreeMap`

In addition, Oracle provided us with several partial implementation classes including `AbstractSet`, `AbstractList`, and `AbstractMap`, which are intended to serve a starting point for new implementations that we choose to define. According to Oracle, these classes provide *a skeletal implementation of the Set, List, and Map interfaces to minimize the effort required to implement those interfaces.*

3.4.5.7 Summary

There are eight core interfaces in the Collections Framework.

As is always the case, each of the core interfaces defines a data type. Each interface declares several methods. In addition, each interface provides a contract that applies to each declared method. The contracts become more specific as we traverse down the interface inheritance hierarchy.

Objects instantiated from classes that implement the interfaces can be considered to be of the interface type or any ancestor interface in the interface's hierarchical family tree.

The method declarations and their associated contracts in the interfaces specify the general behavior of matching methods in the classes that implement the interfaces.

The framework provides several concrete implementations of the interfaces that we can use to instantiate new objects to use as data structures or data containers.

The framework also provides several abstract implementations that we can use as a starting point for defining our own implementations.

Answer 4 (p. 948)

3.4.6.3.5 Question 5

True or False? In Java, a *collection* is an object of some type, and that type is defined in a generic sense by one or more interfaces that make up the Collections Framework.

Answer 5 (p. 948)

3.4.6.3.6 Question 6

True or False? All data types specify the operations that can be performed on an entity of that type as well as the kinds of data that can be stored in an entity of that type.

Answer 6 (p. 948)

3.4.6.3.7 Question 7

True or False? An object in Java can often be considered to be of several different types.

Answer 7 (p. 948)

3.4.6.3.8 Question 8

True or False? While a class in Java represents a data type, the same is not true for a Java interface.

Answer 9 (p. 947)

3.4.6.3.10 Question 10

True or False? A Java interface in the *Collections Framework* specifies the type of an object instantiated from a class that implements the interface. The interface also provides a generic representation of the operations that apply across different implementations of the interface.

False. The contract for the **add** method, as declared in the **Collection** interface, does not prohibit duplicate elements, but does make the provision for interfaces that extend **Collection** to prohibit duplicate elements. The contract for the **add** method in the **Set** interface does prohibit duplicate elements.

3.4.6.4.7 Answer 14

False. If you define a class that implements the `Collection` interface in a manner consistent with the *Collections Framework*, you must make certain that each of your methods behaves as described in the Oracle documentation. In other words, you must be careful to comply with the *contract* defined for those methods. If you don't do that, a user can't rely on objects instantiated from your class to exhibit proper behavior.

3.4.6.4.10 Answer 11

False. there is no technical requirement for a specification of the behavior of the interface methods when implemented in a class. In fact, because a method that is declared in an interface is abstract, it specifically refrains from defining the behavior of the method. The interface definition simply declares the interfaces for all the methods that it declares.

3.4.7.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java Collections Framework in particular.

This module explains how the core collection interfaces in the Java Collections Framework allow collections to be manipulated without regard for how they are implemented. The framework provides nine or more concrete implementations of the interfaces. The framework also provides various algorithms for manipulating the data in the collections.

In addition to studying these modules, I strongly recommend that you study the Collections Trail ⁴⁴⁴ in Oracle's Java Tutorials ⁴⁴⁵. The modules in this collection are intended to supplement and not to replace those tutorials.

3.4.7.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the listings while you are reading about them.

3.4.7.3 Preview

At least three things are included in the Java *Collections Framework*:

- interfaces
- implementations
- algorithms

The previous module discussed the purpose of the interfaces. This module will discuss the purpose of the implementations and the algorithms in the Collections Framework.

⁴⁴⁵<http://docs.oracle.com/javase/tutorial/index.html>

3.4.7.4 Generics

The code in this series of modules is written with no thought given to Generics ⁴⁴⁶ . As a result, if you copy and compile the code, you will probably get warnings about *unchecked or unsafe operations* .

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.7.5 Introduction

We learned in an earlier module that the framework provides at least nine concrete implementations of the interfaces in the framework. These nine implementation classes are available for immediate instantiation to produce objects to satisfy your collection needs.

We also learned that the framework provides at least three incomplete implementations. These classes are available for you to use as a starting point in defining your own implementations. Default implementations of many of the interface methods are provided in the incomplete implementations.

3.4.7.6 Discussion and sample code

3.4.7.6.1 Purpose of implementations

The *implementations* in the Java Collections Framework are the concrete definitions of the classes that implement the *core collection interfaces* . For example, concrete implementations in the Java Collections Framework are provided by at least the following nine classes.

- HashSet
- TreeSet
- LinkedList
- ArrayList
- Vector
- HashMap
- WeakHashMap
- TreeMap
- Hashtable

3.4.7.6.1.1 Available for immediate use

These classes are available for immediate use to instantiate collection objects.

As you can see, there are two classes that obviously fall into the *Set* category, two that obviously fall into the *List* category, and three that obviously fall into the *Map* category. You can learn more about the detailed characteristics of those classes in the standard Java documentation and in The Java Tutorials ⁴⁴⁷ .

This leaves two additional classes whose names don't readily divulge the category to which they belong.

3.4.7.6.1.2 Vector and Hashtable classes

The classes **Vector** and **Hashtable** were part of Java even before the Java Collections Framework became available. The **Vector** class can be used to instantiate objects that fall in the general *List* category.

The **Hashtable** class can be used to instantiate objects that fall in the *Map* category.

These two classes have been upgraded to make them compatible with the Collections Framework.

⁴⁴⁶<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

⁴⁴⁷<http://docs.oracle.com/javase/tutorial/collections/interfaces/index.html>

3.4.7.6.1.3 Abstract implementations

In addition to the concrete implementations listed above, the following three classes partially implement the interfaces, but are not intended for instantiation. Rather, they are intended to be extended into new concrete classes that you define.

- AbstractSet
- AbstractList
- AbstractMap

Therefore, by either using one of the three classes listed above as a starting point, or by starting from scratch and fully implementing one or more of the interfaces, you can provide new concrete implementations to augment the framework to include collections that meet your special needs. If you do that, be sure to satisfy the contract requirements of the Collections Framework in addition to the technical requirements imposed by implementing interfaces.

3.4.7.6.2 Purpose of algorithms

Algorithms are methods (*not necessarily exposed*) that provide useful capabilities, such as searching and sorting. For example, the **Collection** interface declares an exposed method named **contains** .

3.4.7.6.2.1 The contains method

The contract for the **contains** method requires that the method:

- receives an incoming reference of type **Object** as a parameter
- searches the collection looking for an element that matches the incoming reference
- returns true if the collection on which the method is called contains the specified element and returns false otherwise.

3.4.7.6.2.2 Different classes, different implementations

You can safely call the **contains** method on any object instantiated from a class that properly implements the **Collection** interface, even if you don't know the actual type of the collection object.

The manner in which the search will be performed will probably differ from one concrete implementation of the interface to the next. For example, a **TreeSet** object will perform the search very rapidly with a time cost of only $\log(n)$ where n is the number of elements. On the other hand, for the same number of elements, because of a different underlying data structure, a search on an **ArrayList** object will probably require more time than a search on a **TreeSet** object. As the number of elements increases, the difference in time cost between the two will also increase.

3.4.7.6.3 A sample program

Consider the sample program shown in Listing 1 (p. 952) . This program compares the search speed of the **ArrayList** class and the **TreeSet** class. A detailed discussion of the program follows Listing 1 (p. 952) .

Table 3.367

3.4.7.6.3.1 Instantiate and populate a TreeSet object

The program begins by instantiating a **TreeSet** object and populating it with approximately 2,000,000 elements as shown in Listing 2 (p. 954) . The values encapsulated in the objects referred to by the elements in the collection are produced by a random number generator.

Recall that the **add** method of a **Set** object rejects duplicate elements, so there may be fewer than 2,000,000 elements in the object after it is populated, depending on how many of the random values are duplicates.

Listing 2 . Beginning of the doIt method.

```
public void doIt(){
int size = 2000000;

Collection aTree = new TreeSet();

Random rnGen = new Random();
for(int ct = 0; ct < size; ct++){
    aTree.add(new Double(rnGen.nextDouble()));
} //end for loop
```

Table 3.368

3.4.7.6.3.2 Instantiate and populate an ArrayList object

One of the capabilities of the Collection Framework is to create a new **Collection** object and populate it with the contents of an existing **Collection** object of a different (*or the same*) actual type.

The code in Listing 3 (p. 954) instantiates an **ArrayList** object and populates it with the contents of the existing **TreeSet** object. As a result, we then have two different **Collection** objects of different actual types containing the same elements.

Listing 3 . Instantiate and populate an ArrayList object.

```
Collection aList = new ArrayList(aTree);
```

Table 3.369

3.4.7.6.3.3 Identify a target element

The objective of this program is to compare the times required to search for and to find an element in each of the collections. Thus, we need a target element to search for.

The code in Listing 4 (p. 955) extracts a value near the center of the `ArrayList` object using an index to find and extract the value. This is a very fast operation on a `List` object. This value is saved in `testVal` to be used later for test purposes.

Note that the reference to the `ArrayList` object was saved as type `Collection` (and not as type `ArrayList`) in Listing 3 (p. 954) above.

Note also that it was necessary to cast that reference to type `List` in Listing 4 (p. 955) in order to call the `get` method on the reference. This is because the `Collection` interface does not declare a method named `get`. Rather, the `get` method is added to the `List` interface to define a more specialized form of collection.

(Author's note: This program was originally written before the introduction of Generics. The above requirement may not be true if the program were to be rewritten making proper use of Generics.)

Listing 4 . Identify a target element.

```
Object testVal = ((List)aList).get(size/2);
```

Table 3.370

3.4.7.6.3.4 Search for the test value in each collection

The code in Listing 5 (p. 955) calls the `contains` method to search for the test value in each of the collections. It uses the system clock to measure the time required to find the element in each case. *(I will assume that you understand how to use the `Date` class for this purpose, and won't provide a detailed explanation.)*

Listing 5 . Search for the test value in each collection.

```
    long start = new Date().getTime();
    boolean found = aList.contains(testVal);
    long stop = new Date().getTime();
    System.out.println(found + " " + (stop - start));

    start = new Date().getTime();
    for(int x = 0; x < 100000; x++){
        found = aTree.contains(testVal);
    }//end for loop
    stop = new Date().getTime();
    System.out.println(found + " " + (stop - start)/100000.0);

} //end doIt()
```

Table 3.371

3.4.7.6.3.5 Program output

Running the program several times produced the following range of output values:

- First output value ranged from "true 93" to "true 109"
- Second output value ranged from "true 0.00031" to "true 0.00046"

The first output value applies to the `ArrayList` object, and the second output value applies to the `TreeSet` object.

As we would expect, the test value was successfully found in both cases; hence the display of true in both cases.

3.4.7.6.3.6 Time required to search the ArrayList collection

The output indicates that approximately 100 milliseconds were required to find the test value in the `ArrayList` object.

3.4.7.6.3.7 Time required to search the TreeSet collection

The time required to find the test value in the `TreeSet` object was so small that it wasn't even measurable within the granularity of the system clock (*other experiments have caused me to believe that the granularity of the system clock on this machine is at least sixteen milliseconds*). Hence, the original reported time required to find the test value in the `TreeSet` object was zero.

In order to get a measurable time value to search the `TreeSet` object, I had to wrap the invocation of the `contains` method in a for-loop and search for the same value 100,000 times in succession. Thus, the time required to find the test value in the `TreeSet` object was approximately 0.00030 milliseconds as compared to 100 milliseconds for the `ArrayList` object.

(I'll let you do the arithmetic to see if this makes sense in terms of the expected time cost to search the two different types of collections. Don't forget the extra overhead of the for-loop.)

3.4.7.6.3.8 Different implementations

This is a graphic demonstration that even though both objects can be treated as type `Collection`, and the `contains` method can be called on either object in a polymorphic manner, the actual implementations of the two objects and the implementations of the `contains` methods in those two objects are different.

Each type of collection has advantages and disadvantages, depending on your needs.

3.4.7.6.3.9 Polymorphic behavior applies

The important point is that if you receive a reference to the collection object as type `Collection`, you can call the `contains` method on that reference without regard to the underlying structure of the collection object. This is because *polymorphic* behavior applies.

Very briefly, polymorphic behavior means that the actual method that is executed is the appropriate method for that type of object regardless of the actual type (*class*) of the reference to the object. This is one of the great advantages of using the Java Collections Framework and passing collection objects among methods as interface types.

3.4.7.6.4 Sorting algorithms

Some of the implementations of the Java Collection Framework maintain their elements in a random order, and other implementations maintain their elements in a sorted order. Thus, the framework also provides sorting algorithms. However, the sorting algorithms used to maintain the order of the collections are not

exposed in the way that the search algorithm is exposed (via the **contains** method). Rather, the sorting algorithms are implicit in those implementations that need them, and are absent from those implementations that don't need them.

3.4.7.6.5 Now for a little quiz

Let's see if you are still awake. Select the words in one pair of parentheses in the following statement that causes the statement to be true.

The interfaces in the Collections Framework make it possible to manipulate the contents of collections in a manner that is (dependent on) (independent of) the underlying implementation of each collection.

3.4.7.6.5.1 And the answer is ...

The interfaces in the Collections Framework make it possible to manipulate the contents of collections in a manner that is **independent of** the underlying implementation of each collection. That is the beauty of basing the framework on interfaces that declare polymorphic methods.

3.4.7.6.5.2 Drive home the point

I placed this question here to drive home the point that the methods declared in the **Collection** interface can be called on collection objects in a *polymorphic* manner.

That is to say, as a user of an object instantiated from a class that properly implements the **Collection** interface (according to the contracts of the Collections Framework), you can call the methods declared in that interface on a reference to the object and be confident that the actual method that is called will be the version that is appropriate for the class from which the object was instantiated. This is polymorphic behavior.

In the event that you need to call a method that is not declared in the **Collection** interface (such as the *get()* method in Listing 4 (p. 955) above), you can pass the reference as one of the more specialized sub-interfaces of **Collection**, such as **Set**.

(Author's note: Once again, this document was originally written before the release of Generics. The use of the more specialized sub-interfaces described above may not be required if the program is re-written making proper use of Generics.)

3.4.7.6.6 Benefits of using the Collections Framework

The Java Tutorial ⁴⁴⁸ from Oracle lists and explains the benefits of using the Java Collections Framework, including the following.

- It reduces programming effort
- It increases program speed and quality
- It allows interoperability among unrelated APIs
- It reduces the effort to learn and use new APIs
- It reduces effort to design new APIs
- It fosters software reuse

For a detailed explanation of these benefits, I am simply going to refer you directly to The Java Tutorial ⁴⁴⁹.

⁴⁴⁸<http://docs.oracle.com/javase/tutorial/collections/interfaces/index.html>

⁴⁴⁹<http://docs.oracle.com/javase/tutorial/collections/interfaces/index.html>

3.4.7.7 Run the program

I encourage you to copy the code from Listing 1 (p. 952) and paste it into a Java source code file. Then compile and execute it.

Run the program and observe the results. Experiment with the code. Make changes, run the program again, and observe the results of your changes. Make certain that you can explain why your changes behave as they do.

3.4.7.8 Summary

Let's recap some of what we have learned in this and the previous modules.

The core collection interfaces in the Collections Framework are shown below.

- Collection
 - Set
 - * SortedSet
 - List
 - Queue
 - Deque
- Map
 - SortedMap

The basic purpose of the core collection interfaces in the Java Collections Framework is to allow collections to be manipulated without regard for how the collections are implemented, provided of course that the implementations comply with the contracts.

The framework provides at least the following nine concrete implementations (*classes*) of the interfaces shown above:

- HashSet
- TreeSet
- LinkedList
- ArrayList
- Vector
- HashMap
- WeakHashMap
- TreeMap
- Hashtable

For example, the classes **TreeSet** and **ArrayList** are concrete implementations of the **Collection** interface as shown in the above list.

(Actually, they are concrete implementations of sub-interfaces of Collection. The Collections Framework doesn't provide any direct implementations of the Collection interface.)

A collection object instantiated from the class **TreeSet** and a collection object instantiated from the class **ArrayList** can each be viewed as being of the interface type **Collection**.

Methods having the same signatures can be used to manipulate either collection with confidence that the behavior of the method will be appropriate for the actual type of collection involved.

The framework also provides the following incomplete implementations of the core interfaces:

- AbstractSet
- AbstractList
- AbstractMap

The purpose of these implementations is to provide you with a starting point for defining your own concrete implementations for more specialized collections.

Answer 5 (p. 968)

3.4.8.3.6 Question 6

True or False? The contract for the **contains** method requires that the method:

- receives an incoming reference of type **Object** as a parameter

Answer 6 (p. 968)

3.4.8.3.7 Question 7

Answer 7 (p. 968)

3.4.8.3.8 Question 8

True or False? When you call the **contains** method on a **Collection** object, the manner in which the search will be performed will be the same regardless of the class from which the object was instantiated.

Answer 8 (p. 968)

3.4.8.3.9 Question 9

The program shown in Listing 1 (p. 963) will be used for several different questions.

        //Create and populate an ArrayList
        // object with the same random

Table 3.372

True or False? The program shown in Listing 1 (p. 963) compares the search speed of the **ArrayList** class and the **TreeSet** class.

Answer 9 (p. 967)

3.4.8.3.10 Question 10

True or False? The program shown in Listing 1 (p. 963) instantiates a **TreeSet** object and populates it with approximately 10,000,000 elements.

Answer 10 (p. 967)

3.4.8.3.11 Question 11

True or False? Because the **add** method of a **Set** object rejects duplicate elements, there may be fewer than 2,000,000 elements in the **TreeSet** object in Listing 1 (p. 963) after it is populated, depending on how many of the random values are duplicates.

Answer 11 (p. 967)

3.4.8.3.12 Question 12

True or False? One of the capabilities of the Collection Framework is to create a new **Collection** object and populate it with the contents of an existing **Collection** object of a different (*or the same*) actual type.

Answer 12 (p. 967)

3.4.8.3.13 Question 13

True or False? The code in Listing 1 (p. 963) instantiates an **ArrayList** object and populates it with exactly 2,000,000 random values that are different from the random values contained in the **TreeSet** object.

Answer 13 (p. 967)

3.4.8.3.14 Question 14

True or False? The **ArrayList** object in Listing 1 (p. 963) may contain duplicate values.

Answer 14 (p. 967)

3.4.8.3.15 Question 15

True or False? Listing 1 (p. 963) calls the **get** method on the **ArrayList** object. The **ArrayList** class implements the **List** interface. The **get** method of the **List** interface is inherited from the **Collection** interface.

Answer 15 (p. 967)

3.4.8.3.16 Question 16

True or False? In general, the time required for the **contains** method to find a value in a **TreeSet** object is less than the time required for the **contains** method to find a value in an **ArrayList** object.

Answer 16 (p. 967)

3.4.8.3.17 Question 17

True or False? The very fast searching speed of a **TreeSet** object results from the implementation of the **Set** interface.

Answer 17 (p. 966)

3.4.8.3.18 Question 18

True or False? Polymorphic behavior means that the actual method that is executed on a **Collection** object is the appropriate method for that type of object regardless of the actual type (*class*) of the reference to the object.

Answer 18 (p. 966)

3.4.8.3.19 Question 19

True or False? Some of the implementations of the Java Collections Framework maintain their elements in a random order, and other implementations maintain their elements in a sorted order. The sorting algorithms used to maintain the order of the collections in the Collections Framework are exposed in the same way that the search algorithm is exposed (*via the **contains** method*).

Answer 19 (p. 966)

3.4.8.3.20 Question 20

True or False? The interfaces in the Collections Framework make it possible to manipulate the contents of collections in a manner that is independent of the underlying implementation of each collection.

Answer 20 (p. 966)

3.4.8.5 Answers

3.4.8.5.1 Answer 20

True.

Back to Question 20 (p. 965)

3.4.8.5.2 Answer 19

False. The sorting algorithms used to maintain the order of the collections in the Collections Framework are not exposed in the way that the search algorithm is exposed (*via the **contains** method*). Rather, the sorting algorithms are implicit in those implementations that need them, and are absent from those implementations that don't need them.

Back to Question 19 (p. 965)

3.4.8.5.3 Answer 18

True.

Back to Question 18 (p. 965)

3.4.8.5.4 Answer 17

False. While implementation of the **Set** interface may have some minor impact on the searching speed of a **TreeSet** object, the primary reason for the fast searching speed is the fact that the implementation uses a tree structure.

Back to Question 17 (p. 964)

3.4.8.5.5 Answer 16

True. A **TreeSet** object will perform the search very rapidly with a time cost of only $\log(n)$ where n is the number of elements. On the other hand, for the same number of elements, because of a different underlying data structure, a search on an **ArrayList** object will probably require more time than a search on a **TreeSet** object. As the number of elements increases, the difference in time cost between the two will also increase.

Back to Question 16 (p. 964)

3.4.8.5.6 Answer 15

False. The **Collection** interface does not declare a method named `get`. Rather, the `get` method is added to the **List** interface to define a more specialized form of collection.

Back to Question 15 (p. 964)

3.4.8.5.7 Answer 14

False. While an **ArrayList** object may contain duplicate values, the **ArrayList** object in Listing 1 (p. 963) was populated with the values contained in the **TreeSet** object, which does not allow duplicate values. Therefore, in this case, the **ArrayList** object may not contain duplicate values.

Back to Question 14 (p. 964)

3.4.8.5.8 Answer 13

False. The code in Listing 1 (p. 963) instantiates an **ArrayList** object and populates it with the contents of the existing **TreeSet** object. As a result, we then have two different **Collection** objects of different actual types containing the same elements.

Back to Question 13 (p. 964)

3.4.8.5.9 Answer 12

True.

Back to Question 12 (p. 964)

3.4.8.5.10 Answer 11

True.

Back to Question 11 (p. 964)

3.4.8.5.11 Answer 10

False. The program shown in Listing 1 (p. 963) instantiates a **TreeSet** object and populates it with approximately **2,000,000** elements.

3.4.8.5.12 Answer 9

True.

Back to Question 9 (p. 962)

3.4.8.5.13 Answer 8

False. The manner in which the search will be performed will probably differ from one concrete implementation of the interface to the next. For example, a **TreeSet** object will perform the search very rapidly with a time cost of only $\log(n)$ where n is the number of elements. On the other hand, for the same number of elements, because of a different underlying data structure, a search on an **ArrayList** object will probably require more time than a search on a **TreeSet** object. As the number of elements increases, the difference in time cost between the two will also increase.

3.4.8.5.14 Answer 7

True.

Back to Question 7 (p. 961)

3.4.8.5.15 Answer 6

False.

The contract for the **contains** method requires that the method:

- receives an incoming reference of type **Object** as a parameter
- searches the collection looking for an element that matches the incoming reference
- returns **true** if the collection on which the method is called contains the specified element and returns **false** otherwise.

3.4.8.5.16 Answer 5

True.

Back to Question 5 (p. 961)

3.4.8.5.17 Answer 4

False. Iterator is not one of the concrete implementations.

True.

3.4.9.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java Collections framework in particular.

The *Java Collections Framework* defines eight core interfaces, in two distinct trees. You will learn about the inheritance structure and the purpose of those interfaces. You will also learn how the interfaces declare polymorphic methods that apply to implementations of the interfaces, and you will learn about the optional methods of the **Collection** and **Map** interfaces.

In addition to studying these modules, I strongly recommend that you study the Collections Trail ⁴⁵⁷ in Oracle's Java Tutorials ⁴⁵⁸. The modules in this collection are intended to supplement and not to replace those tutorials.

3.4.9.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the listings while you are reading about them.

3.4.9.2.1.1 Listings

- Listing 1 (p. 972) . The program named `Ap401`.
- Listing 2 (p. 973) . The `Populator` class.
- Listing 3 (p. 974) . Create and populate a `TreeSet` object.
- Listing 4 (p. 974) . Create and populate an `ArrayList` object.

3.4.9.3 Preview

In earlier modules, you learned that at least three things are included in a collections framework:

- interfaces
- implementations
- algorithms

Earlier modules provided a general discussion of the purpose of the interfaces, implementations, and algorithms in the *Collections Framework*. This module takes that discussion further and illustrates the use of the *core collection interfaces*.

The Java Collections Framework defines eight core interfaces, in two distinct trees. You will learn the names and the inheritance structure of those interfaces. You will also learn about the purpose of some of those interfaces. You will see how the interfaces declare polymorphic methods that apply to implementations of the interfaces, and you will learn about the optional methods of the **Collection** interface.

3.4.9.4 Generics

The code in this series of modules is written with no thought given to Generics⁴⁵⁹. As a result, if you copy and compile the code, you will probably get warnings about *unchecked or unsafe operations*.

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.9.5 Discussion and sample code

3.4.9.5.1 Illustration of core collection interfaces

We will begin this module with a little quiz. Take a look at the program shown in Listing 1 (p. 972) and see if you can answer the following question.

What output does the program in Listing 1 (p. 972) produce?

- A. Compiler Error
- B. Runtime Error
- C. 44321 44321
- D. 12344 12344
- E. 1234 44321
- F. 1234 4321
- D. None of the above.

⁴⁵⁹<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

Listing 1 . The program named Ap401.

```

import java.util.TreeSet;
import java.util.ArrayList;
import java.util.Collection;
import java.util.Iterator;

public class Ap401{
    public static void main(String args[]){
        new Worker().doIt();
    }//end main()
} //end class Ap401

class Worker{
    public void doIt(){
        Collection ref = new TreeSet();
        Populator.fillIt(ref);
        Iterator iter = ref.iterator();
        while(iter.hasNext()){
            System.out.print(iter.next());
        }//end while loop
        System.out.print(" ");

        ref = new ArrayList();
        Populator.fillIt(ref);
        iter = ref.iterator();
        while(iter.hasNext()){
            System.out.print(iter.next());
        }//end while loop
        System.out.println();
    }//end doIt()
} // end class Worker

class Populator{
    public static void fillIt(Collection ref){
        ref.add(new Integer(4));
        ref.add(new Integer(4));
        ref.add(new Integer(3));
        ref.add(new Integer(2));
        ref.add(new Integer(1));
    }//end fillIt()
} //end class populator

```

Table 3.373

If you selected the following answer, then you are correct.

E. 1234 44321

The program in Listing 1 (p. 972) illustrates the basic purpose of the core collection interfaces in the Java Collections Framework. That purpose is to allow collections to be manipulated without regard for how the collections are implemented.

3.4.9.5.1.1 Multiple list implementations

For example, there is more than one way to implement a list. Two common ways involve arrays and linked structures. If two lists are implemented in different ways, but both satisfy the requirements of the core collection interfaces, they can each be manipulated the same way regardless of the details of their implementation.

3.4.9.5.1.2 TreeSet and ArrayList

A collection of type **TreeSet** and a collection of type **ArrayList** are instantiated in the program in Listing 1 (p. 972) . Each of the collections is viewed as being of the interface type **Collection** . A method named **add** is used to populate each collection with the same values in the same order.

3.4.9.5.1.3 Behavior is different but appropriate

The behavior of the **add** method is appropriate, and different in each of the two cases, with the final contents of each collection being determined by the respective behavior of the **add** method for that type of collection.

3.4.9.5.2 The fillIt method

The code in the fragment shown in Listing 2 (p. 973) defines a *static* method named **fillIt** of the class named **Populator** . This is a class of my own design intended solely to illustrate the primary point of this program.

The method named **fillIt** receives an incoming reference to a collection object as type **Collection** . The method calls the **add** method on the incoming reference five times in succession to add five elements to the collection. These elements are added without regard for the actual type or underlying implementation of the collection. (*As written, the **fillIt** method has no way of knowing the underlying implementation.*)

Listing 2 . The Populator class.

```
class Populator{
public static void fillIt(Collection ref){
    ref.add(new Integer(4));
    ref.add(new Integer(4));
    ref.add(new Integer(3));
    ref.add(new Integer(2));
    ref.add(new Integer(1));
} //end fillIt()
} //end class populator
```

Table 3.374

The **fillIt** method will be used to populate two collections of different types with the same data values in the same order.

3.4.9.5.3 Create and populate a TreeSet object

Consider the code fragment shown in Listing 3 (p. 974) .

Listing 3 . Create and populate a TreeSet object.

```

    Collection ref = new TreeSet();
    Populator.fillIt(ref);
    Iterator iter = ref.iterator();
    while(iter.hasNext()){
        System.out.print(iter.next());
    }//end while loop

```

Table 3.375

The code in Listing 3 (p. 974) instantiates an object of type **TreeSet** , and passes that object's reference to the **fillIt** method as type **Collection** . As described above, the **fillIt** method adds five elements to the collection, in random order with two of the elements being duplicates.

"Note that this program does not use the syntax for Generics. Therefore, if you copy and compile this program, you will probably see a warning regarding unchecked or unsafe operations"

3.4.9.5.3.1 Display the collection's contents

Then the code in Listing 3 (p. 974) gets an **Iterator** object on the collection and uses the iterator to display the contents of the collection.

3.4.9.5.3.2 TreeSet object is type SortedSet

The **TreeSet** class implements one of the core collection interfaces named **SortedSet** . **SortedSet** extends (is a child (p. 975) of) **Set** . One of the characteristics of a **Set** object is that it doesn't allow duplicate elements. One of the characteristics of a **SortedSet** object is that, by default, it maintains its elements in ascending natural order. Since the **TreeSet** class implements both of these interfaces, it is both a **Set** and a **SortedSet** , and exhibits the characteristics of both interfaces.

Because the underlying structure of the **TreeSet** class doesn't allow duplicates, and the underlying structure maintains its elements in ascending order, the code in Listing 3 (p. 974) produces the following text on the screen:

```
1234
```

3.4.9.5.4 Create and populate an ArrayList object

Now consider the code fragment shown in Listing 4 (p. 974) .

Listing 4 . Create and populate an ArrayList object.

```

    ref = new ArrayList();
    Populator.fillIt(ref);
    iter = ref.iterator();
    while(iter.hasNext()){
        System.out.print(iter.next());
    }//end while loop

```

Table 3.376

The code in Listing 4 (p. 974) instantiates a new collection of type `ArrayList`, and passes that object's reference to the same `fillIt` method, once again as type `Collection`.

The code in the `fillIt` method adds five elements having the same values as before to the collection and adds them in the same order as before. The added elements are references to `Integer` objects encapsulating the same values as were earlier added to the `TreeSet` collection. Although they are physically different objects, the result is that essentially the same data is added to both collections.

3.4.9.5.4.1 Display the collection's contents

Then, as before, the code in Listing 4 (p. 974) gets an iterator and uses it to access and display the contents of the `ArrayList` collection.

The `ArrayList` class implements the `List` interface, which does not prohibit duplicate elements, and does not maintain its elements in sorted order. Therefore, in this case, the following text was displayed:

```
44321
```

All five element values are displayed, including the duplicate, in the order in which they were added to the list.

3.4.9.5.5 The important point

The important point is that although the `fillIt` method calls the same method name (`add`) on each of the collection objects, the behavior of that method is different in each case. In both cases, the behavior is appropriate for the underlying data structure. Furthermore, the underlying data structure isn't even known to the `fillIt` method.

3.4.9.5.5.1 No duplicate elements in ascending order

In the first case, where the underlying data structure was a `TreeSet` object (type `SortedSet`), the duplicate element was eliminated, and the elements were stored so as to be accessible in ascending order.

3.4.9.5.5.2 Duplicates allowed with no sorting

In the second case, where the underlying data structure was an `ArrayList` object (type `List`), all five elements, including the duplicate element were stored in the collection. Furthermore, they were stored and later retrieved in the same order in which they were added.

3.4.9.5.6 Structure of the core interfaces

The *core collection interfaces* in the Java Collections Framework do not all extend from a common root interface.

Rather, the inheritance structure of the core interfaces is shown below. Indentation is used to indicate the **parent-child relationships** among the interfaces.

- Collection
 - Set
 - * SortedSet
 - List
 - Queue
 - Deque
- Map
 - SortedMap

3.4.9.5.7 A Map is not a true Collection

As you can see, that there is no common root interface. Rather, there are two distinct trees, one rooted by **Collection** and the other rooted by **Map**. According to The Java Tutorial from Oracle, "*a Map is not a true Collection.*" I will have more to say about this in a future module.

3.4.9.5.8 Some operations are optional

Every class that implements an interface in the tree rooted in **Collection** is not required to support all of the methods (*operations*) declared in the **Collection** interface.

Rather, some of the methods in the **Collection** interface are designated as "optional operation" in the documentation. (*See the list of optional methods for the Collection interface below.*)

According to the contract for the Collections Framework, if a given implementation doesn't support a specific method, it must throw an **UnsupportedOperationException**. The author of the implementation is responsible for providing documentation that identifies the optional operations that the implementation does and does not support.

3.4.9.5.8.1 Support for optional operations

This should not be an issue unless you are either defining your own implementation, or using an implementation defined by someone other than the programmers at Oracle. All of the general-purpose implementations from Oracle appear to support all of the optional operations.

3.4.9.5.8.2 Optional Collection operations

The following list shows the optional operations in the **Collection** interface. Each of these methods has the ability to modify the contents of the collection.

- add()
- addAll()
- clear()
- remove()
- removeAll()
- retainAll()

3.4.9.5.8.3 Optional Map operations

The following list shows the optional operations in the **Map** interface. Each of these methods also has the ability to modify the contents of the map.

- clear()
- put()
- putAll()
- remove()

3.4.9.5.8.4 Many methods are not optional

In both cases, the interface declares numerous other methods that are not optional. Generally, the non-optional methods don't have the ability to modify the collection. For example, the **get** method of the **Map** interface is not optional. Although the **get** method receives an incoming *key* and returns the *value* to which the key maps, the method doesn't have the ability to modify the contents of the collection.

3.4.9.6 Run the program

I encourage you to copy the code from Listing 1 (p. 972) and paste it into your Java editor. Then compile and execute it.

Run the program and observe the results. Experiment with the code. Make changes, run the program again, and observe the results of your changes. Make certain that you can explain why your changes behave as they do.

3.4.9.7 Summary

A collections framework contains at least the following items:

- interfaces
- implementations
- algorithms

The *Java Collections Framework* defines eight core interfaces, in two distinct trees. One tree is rooted in **Collection** and the other is rooted in **Map**.

The basic purpose of the core interfaces is to make it possible for collections to be manipulated without regard for how they are implemented, so long as the implementation satisfies the contracts of the interfaces.

When the same method name (*and signature*) is called on references to collections of different types, the behavior of the method is likely to be different for each collection. However, in each case, that behavior will be appropriate for the type of collection object on which the method is called. This is polymorphic behavior.

Six of the methods declared in the **Collection** interface are optional insofar as being supported by implementing classes is concerned. The optional methods all have the ability to modify the contents of the collection. Those implementing classes that don't support an optional method must throw an **UnsupportedOperationException** if that method is called on an object of the class. Similarly four of the methods declared in the **Map** interface are optional.

Many methods declared in the **Collection** interface are not optional. Generally, the non-optional methods don't have the ability to modify the collection.

3.4.9.8 What's next?

In the next module, I will discuss and illustrate some of the details of the core interfaces and the general-purpose implementations in the Java Collections Framework. For example, I will discuss the difference between a *set* and a *list*. I will also discuss the difference between *ordered* and *sorted*. I will discuss the fact that additional stipulations are applied as you progress down the framework interface hierarchy. In order to help you learn and retain the material, I will provide a couple of short quizzes.

3.4.10.5.1 Answer 15

False. Every class that implements an interface in the tree rooted in **Collection** is **not** required to support all of the methods (*operations*) declared in the **Collection** interface.

Rather, some of the methods in the **Collection** interface are designated as "optional operation" in the documentation.

3.4.10.5.3 Answer 13

True.

Back to Question 13 (p. 982)

3.4.10.5.4 Answer 12

False. In Listing 1 (p. 980), the `fillIt` method receives an incoming parameter that is a reference to a collection object. The `fillIt` method calls the `add` method on the incoming reference several times in succession to add elements to the collection, without regard for the actual type or underlying implementation of the collection object. *(As written, the `fillIt` method has no way of knowing the actual type or underlying implementation of the collection object.)*

Back to Question 12 (p. 982)

3.4.10.5.5 Answer 11

False. By implementing the `SortedSet` interface, the `TreeSet` object is required to present its contents to an iterator in ascending natural order. The `ArrayList` object is not subject to such a contract. Therefore, the `TreeSet` object presents its contents to the iterator as 1234 *(with no duplicate elements)* while the `ArrayList` object presents its contents to the iterator as 44321, which is the same order that the values were added to the object.

Back to Question 11 (p. 982)

3.4.10.5.6 Answer 10

False. The `TreeSet` class implements the `SortedSet` interface. `SortedSet` is a sub interface of `Set`. One of the characteristics of a `Set` object is that it doesn't allow duplicate elements. The `ArrayList` class is not subject to such a contract. Therefore, the `ArrayList` object ends up containing duplicate copies of the value 4 while the `TreeSet` object ends up with no duplicates.

3.4.10.5.7 Answer 9

True.

Back to Question 9 (p. 981)

3.4.10.5.8 Answer 8

False. Given that both the `TreeSet` class and the `ArrayList` class inherit an abstract method named `add` from the `Collection` interface, each class is required to define a concrete version of the `add` method but those two methods are not required to exhibit the same behavior. The behavior of the `add` method for each class should be appropriate for the type of object instantiated from the class.

3.4.11.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java Collections framework in particular.

In addition to studying these modules, I strongly recommend that you study the Collections Trail⁴⁶⁷ in Oracle's Java Tutorials⁴⁶⁸. The modules in this collection are intended to supplement and not to replace those tutorials.

⁴⁶⁴This content is available online at <<http://cnx.org/content/m46141/1.5/>>.

⁴⁶⁷<http://docs.oracle.com/javase/tutorial/collections/index.html>

⁴⁶⁸<http://docs.oracle.com/javase/tutorial/index.html>

3.4.11.3 Preview

You learned in earlier modules that the Java Collections Framework defines eight core interfaces, in two distinct trees. One of the trees, which consists of six interfaces, is rooted in the interface named **Collection**. The other tree, which consists of two interfaces, is rooted in the interface named **Map**.

You learned the names and the inheritance structure of those interfaces. You also learned about their purpose. You saw how the interfaces declare polymorphic methods that apply to implementations of the interfaces, and you learned about the optional methods of the **Collection** interface and the **Map** interface.

In this module you will learn that all of the implementations of the interfaces on the **Collection** side of the Java Collections Framework (*the Collection hierarchy*) implement one of the sub-interfaces of the **Collection** interface. (*A similar discussion regarding the **Map** side of the Java Collections framework will be deferred until a future module.*)

You will learn that a **Set** object cannot contain duplicate elements, but a **List** object can contain duplicate elements.

You will learn about the difference between *ordered* collections and *sorted* collections. You will also learn about *ascending order* and the *natural ordering* of objects.

In addition, you will learn how more specialized stipulations are placed on interfaces as you progress down the interface inheritance hierarchy of the Java Collections Framework.

3.4.11.4 Generics

The code in this series of modules is written with no thought given to Generics⁴⁶⁹. As a result, if you copy and compile the code, you will probably get warnings about *unchecked or unsafe operations*.

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.11.5 Discussion

3.4.11.5.1 We will start with a quiz

I am going to begin this module with a quiz just to make sure that you are still awake. Is the following statement True or False?

*The **TreeSet** class is a direct implementation of the **Collection** interface.*

The answer is False.

The **TreeSet** class is not a direct implementation of the **Collection** interface. Rather, the **TreeSet** class is a direct implementation of the **SortedSet** interface. The **SortedSet** interface extends the **Set** interface, and the **Set** interface extends the **Collection** interface.

The interface hierarchy for the Java Collections Framework is shown below:

- Collection
 - Set
 - * SortedSet
 - List
 - Queue
 - Deque
- Map
 - SortedMap

As you learned in an earlier module, the Java Collections Framework doesn't have a single root. As shown above, there are two distinct trees in the framework – The **Collection** hierarchy and the **Map** hierarchy.

⁴⁶⁹<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

3.4.11.5.2 The root of the Collection hierarchy

The **Collection** interface is the root of the collection hierarchy. The Java Collections Framework doesn't provide any direct implementations of the **Collection** interface. All of the implementations of the interfaces in the **Collection** hierarchy implement one of the sub-interfaces of the **Collection** interface.

3.4.11.5.2.1 What does Oracle say about this?

Here is what the Oracle documentation has to say on the topic of the **Collection** interface:

*"The SDK does not provide any direct implementations of this interface: it provides implementations of more specific sub-interfaces like **Set** and **List**. This interface is typically used to pass collections around and manipulate them where maximum generality is desired."*

The Oracle documentation also states:

"Bags or multisets (unordered collections that may contain duplicate elements) should implement this interface directly."

3.4.11.5.3 What about duplicate elements?

Some implementations of **Collection** allow duplicate elements, and others do not. Implementations of the **List** interface (such as **ArrayList**) allow duplicate elements. Implements of **Set** and **SortedSet** (such as **TreeSet**) do not allow duplicate elements. This was illustrated in an earlier module.

A sample program in that earlier module created two collection objects and applied the polymorphic **add** method to add the same elements to each collection. One of the collection objects was of type **ArrayList**, and the other collection object was of type **TreeSet**. The elements added to each collection contained one pair of duplicate elements. The duplicate element was automatically excluded from the **TreeSet** object, but was retained in the **ArrayList** object.

3.4.11.5.4 What is a set?

According to Oracle, a **Set** is a *"collection that contains no duplicate elements ... this interface models the mathematical set abstraction."*

An object of type **Set** is typically used to model collections such as Social Security numbers, where duplicates are not allowed.

3.4.11.5.5 What is a list?

Also according to Oracle, a **List** is *"An ordered collection (also known as a sequence). The user of this interface has precise control over where in the list each element is inserted. The user can access elements by their integer index (position in the list), and search for elements in the list."*

3.4.11.5.6 Ordered is not the same as sorted

Note that an *ordered* collection is not the same as a *sorted* collection.

The fact that the collection is ordered derives from the fact that each element in the collection has a specific position specified by an index.

In a sorted collection, the position of each element is determined by its value relative to the values of its predecessors and successors.

Oracle goes on to say, *"Unlike sets, lists typically allow duplicate elements. More formally, lists typically allow pairs of elements e1 and e2 such that e1.equals(e2), and they typically allow multiple null elements if they allow null elements at all."*

3.4.11.5.7 Is ascending sort order always required?

Not all implementations of the **Collection** interface maintain the elements in ascending sort order. Some may, and others do not. For example, as discussed above, implementations of the **List** interface (such as **ArrayList**) do not maintain their elements in sorted order at all. In other words, the position of an element in an **ArrayList** does not depend on the value of the element.

On the other hand, implementations of the interface named **SortedSet** (such as **TreeSet**) and the interface named **SortedMap** do maintain their elements in sorted order. However, that order is not necessarily ascending.

When an object is instantiated from a class that implements the **SortedSet** interface, the sorting order for that object can be established by providing an object instantiated from a class that implements the **Comparator**⁴⁷⁰ interface. In that case, the author of the class that implements the **Comparator** interface determines the order imposed on the elements in the collection.

3.4.11.5.7.1 Does case matter in String objects?

For example, if your **SortedSet** object contains references to **String** objects, the natural ascending sort would take the difference between upper case and lower case characters into account.

However, you might prefer that case be ignored when establishing the sorted order. You can accomplish this by providing an object of a class that implements the **Comparator** interface and which defines the **compare** method and the **equals** method in such a way as to eliminate case considerations for comparisons of **String** objects.

3.4.11.5.8 Sub-interfaces have more stipulations

As you progress down the inheritance hierarchy, you find that additional stipulations apply at each level of inheritance. As an example, according to Oracle, *"The Set interface places additional stipulations, beyond those inherited from the Collection interface, on the contracts of all constructors and on the contracts of the **add**, **equals** and **hashCode** methods."*

The important point is that specific sub-interfaces of the **Collection** interface can define requirements that do not apply to all sub-interfaces of the **Collection** interface.

3.4.11.5.8.1 Stipulations on set

For example, the **add** method of the **Set** interface stipulates the following:

"Adds the specified element to this set if it is not already present."

On the other hand, the **add** method of the **Collection** interface simply states:

"Ensures that this collection contains the specified element."

Thus, the contract for the **add** method of an object of a class that implements the **Set** interface is more specialized than the contract for the **add** method of an object of a class that implements the **Collection** interface.

An additional stipulation on the constructor for a **Set** object is that all constructors must create a set that contains no duplicate elements.

⁴⁷⁰http://cnx.org/contents/5_Rd_R2l

3.4.11.5.8.2 Stipulations on SortedSet

The `SortedSet` interface extends the `Set` interface. The `SortedSet` interface contains the following stipulation that makes it more specialized than a `Set` .

"A set that further guarantees that its iterator will traverse the set in ascending element order, sorted according to the natural ordering of its elements (see `Comparable` ⁴⁷¹), or by a `Comparator` provided at sorted set creation time."

3.4.11.5.9 We will end with a quiz

I'm going to finish this module with several questions in the form of a quiz. To ensure that this is a learning experience, I will provide an explanation in addition to the answer for each question.

3.4.11.5.9.1 Question 1

True or False? A collection that implements the `List` interface maintains its elements in ascending alphanumeric order.

The answer to question 1 is False. Unlike collections that implement the `SortedSet` interface, the order of the elements in a collection that implements the `List` interface is not based on the values of the objects referred to by the elements in the list.

3.4.11.5.9.2 Question 2

True or False? A collection that implements the `List` interface is an unordered collection.

The answer to question 2 is also False. A collection that implements the `List` interface is an **ordered** collection (*also known as a sequence*) . According to Oracle, *"The user of the interface has precise control over where in the list each element is inserted."* Elements can be inserted and retrieved on the basis of their integer index (*position in the list*) using the following methods:

- `add(int index, Object element)`
- `get(int index)`

Valid index values are positive integers that begin with zero. When the `add` method is used to insert an element at a specific position in the sequence, the element currently at that position (*if any*) and any subsequent elements are shifted toward higher index values to make room for the new element.

Another version of the `add` method takes a reference to an object as an incoming parameter and appends the specified element to the end of the collection.

The `get` method simply returns the element at the specified position in the collection.

The `List` interface also declares various other methods that can be used to manipulate the contents of the collection.

3.4.11.5.9.3 Question 3

True or False? A collection that implements the `List` interface is allowed to contain duplicate values.

The answer to question 3 is True. Unlike a collection that implements the `Set` interface, a collection that implements the `List` interface is typically allowed to contain duplicate values. More formally, according to Oracle, *"lists typically allow pairs of elements e_1 and e_2 such that $e_1.equals(e_2)$, and they typically allow multiple null elements if they allow null elements at all."*

⁴⁷¹<http://cnx.org/contents/L3qgZmWm>

3.4.11.5.9.4 Question 4

True or False? The contracts of the methods in the **List** interface are the same as the contracts of the methods inherited from the **Collection** interface.

The answer to question 4 is False. According to Oracle, *"The **List** interface places additional stipulations, beyond those specified in the **Collection** interface, on the contracts of the **iterator** , **add** , **remove** , **equals** , and **hashCode** methods."*

For example, the **iterator** method (*for both the **List** and **Collection** interfaces*) returns an iterator over the elements in the collection. For the **Collection** interface, there are no guarantees concerning the order in which the elements are returned by the methods of the **Iterator** object.

On the other hand, the **iterator** method for the **List** interface returns an iterator over the elements in the collection in proper sequence, where the sequence is determined by the numeric index. In other words, when you call the methods of the **Iterator** object on a **List** , the elements will be returned in the proper sequence as determined by a numeric index.

Similarly, according to Oracle, the **SortedSet** interface *"guarantees that its iterator will traverse the set in ascending element order, sorted according to the natural ordering of its elements (see **Comparable**), or by a **Comparator** provided at sorted set creation time."*

3.4.11.6 Summary

In this module you learned that all of the implementations of the interfaces in the **Collection** hierarchy implement one of the sub-interfaces of the **Collection** interface. You learned that a **Set** object cannot contain duplicate elements, but a **List** object can contain duplicate elements.

You learned about the difference between *ordered* collections and *sorted* collections. You also learned about *ascending order* and the *natural ordering* of objects. In addition, you learned how more specialized stipulations are placed on interfaces as you progress down the interface inheritance hierarchy of the Java Collections Framework.

3.4.11.7 What's next?

The **SortedSet** interface *"guarantees that its iterator will traverse the set in ascending element order, sorted according to the natural ordering of its elements (see **Comparable**), or by a **Comparator** provided at sorted set creation time."* In the next module, I will show you how to use the **Comparator** interface to control the sorted order of your collections.

3.4.12.4.1 Answer 23

True.

Back to Question 23 (p. 997)

3.4.12.4.2 Answer 22

True.

Back to Question 22 (p. 997)

3.4.12.4.3 Answer 21

False. The **iterator** method for the **Collection** interface returns an iterator over the elements in the collection where there are no guarantees concerning the order in which the elements are returned by the methods of the **Iterator** object.

Back to Question 21 (p. 997)

3.4.12.4.4 Answer 20

False. According to Oracle, *"The **List** interface places additional stipulations, beyond those specified in the **Collection** interface, on the contracts of the **iterator** , **add** , **remove** , **equals** , and **hashCode** methods."*

Back to Question 20 (p. 997)

3.4.12.4.5 Answer 19

True. Unlike a collection that implements the **Set** interface, a collection that implements the **List** interface is typically allowed to contain duplicate values.

Back to Question 19 (p. 996)

3.4.12.4.6 Answer 18

False. A collection that implements the **List** interface is an ordered collection (*also known as a sequence*). According to Oracle, *"The user of the interface has precise control over where in the list each element is inserted."* Elements can be inserted and retrieved on the basis of their integer index (*position in the list*) using the following methods:

- **add(int index, Object element)**
- **get(int index)**

Valid index values are positive integers that begin with zero.

Another version of the **add** method takes a reference to an object as an incoming parameter and appends the specified element to the end of the collection.

Back to Question 18 (p. 996)

3.4.12.4.7 Answer 17

False. Unlike collections that implement the **SortedSet** interface, the order of the elements in a collection that implements the **List** interface is not based on the values of the objects referred to by the elements in the list.

Back to Question 17 (p. 996)

3.4.12.4.8 Answer 16

True. For example, the **add** method of the **Set** interface stipulates the following:

"Adds the specified element to this set if it is not already present."

On the other hand, the **add** method of the **Collection** interface simply states:

"Ensures that this collection contains the specified element."

Thus, the contract for the **add** method of an object of a class that implements the **Set** interface is more specialized than the contract for the **add** method of an object of a class that implements the **Collection** interface.

Back to Question 16 (p. 996)

3.4.12.4.9 Answer 15

False. You can cause the sort order to ignore case by providing an object of a class that implements the **Comparator** interface, and which defines the **compare method** and the **equals** method in such a way as to eliminate case considerations for comparisons of **String** objects.

Back to Question 15 (p. 996)

3.4.12.4.10 Answer 14

True.

Back to Question 14 (p. 996)

3.4.12.4.11 Answer 13

False. Implementations of the interface named **SortedSet** do maintain their elements in sorted order. However, that order is not necessarily ascending. When an object is instantiated from a class that implements the **SortedSet** interface, the sorting order for that object can be established by providing an object instantiated from a class that implements the **Comparator** interface. In that case, the author of the class that implements the **Comparator** interface determines the order imposed on the elements in the collection.

Back to Question 13 (p. 996)

3.4.12.4.12 Answer 12

False. Not all implementations of the **Collection** interface maintain the elements in ascending sort order. Some may, and others do not. For example, implementations of the **List** interface (*such as **ArrayList***) do not maintain their elements in sorted order at all. In other words, the position of an element in an **ArrayList** does not depend on the value of the element.

Back to Question 12 (p. 996)

3.4.12.4.13 Answer 11

True.

Back to Question 11 (p. 996)

3.4.12.4.14 Answer 10

False. An *ordered* collection is one in which each element in the collection has a specific position specified by an index.

Back to Question 10 (p. 995)

3.4.12.4.15 Answer 9

False. An *ordered* collection is not the same as a *sorted* collection.

3.4.12.4.16 Answer 8

True, according to Oracle.

3.4.12.4.17 Answer 7

True, according to Oracle.

Back to Question 7 (p. 995)

3.4.12.4.18 Answer 6

False.

ArrayList class:

```
public class ArrayList<E> extends AbstractList<E>
implements List<E>, RandomAccess, Cloneable, Serializable
```

The Java Collections Framework doesn't provide any direct implementations of the **Collection** interface. All of the implementations of the interfaces in the **Collection** hierarchy implement one of the sub-interfaces of the **Collection** interface. In the case of the **ArrayList** class, that sub-interface is the **List** interface, which extends the **Collection** interface.

Back to Question 6 (p. 995)

3.4.12.4.19 Answer 5

True.

Back to Question 5 (p. 995)

3.4.12.4.20 Answer 4

False. The **TreeSet** class is not a direct implementation of the **Collection** interface. Rather, the **TreeSet** class is a direct implementation of the **SortedSet** interface. The **SortedSet** interface extends the **Set** interface, and the **Set** interface extends the **Collection** interface.

Back to Question 4 (p. 995)

3.4.12.4.21 Answer 3

False. A **Set** object cannot contain duplicate elements, but a **List** object can contain duplicate elements.

Back to Question 3 (p. 994)

3.4.12.4.22 Answer 2

False. One of the trees, which consists of six interfaces, is rooted in the interface named **Collection**. The other tree, which consists of two interfaces, is rooted in the interface named **Map**.

3.4.13.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java *Collections Framework* in particular.

This is also the first module in a sub-collection on the **Comparable** interface. The purpose of the modules in this sub-collection is to teach you about the interactions between the **Comparable** interface and the Collections Framework, particularly with respect to the **Set** , **SortedSet** , and **SortedMap** interfaces of the Collections Framework.

This module also explains the (*lack of*) interaction between the **Comparable** interface and the Java Collections Framework with respect to collections of type **List** .

In addition to studying these modules, I strongly recommend that you study the Collections Trail ⁴⁷⁹ in Oracle's Java Tutorials ⁴⁸⁰ . The modules in this collection are intended to supplement and not to replace those tutorials.

3.4.13.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the listings while you are reading about them.

3.4.13.3 Preview

In this module, I will begin discussing the interaction between the **Comparable** interface and the Collections Framework.

3.4.13.3.1 Generics

The code in this module is written with no thought given to Generics ⁴⁸¹ . As a result, if you copy and compile this code, you will probably get a warning about *unchecked or unsafe operations* .

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.13.3.2 Specialization

I will provide a concrete example of the specialization that occurs while moving down the interface hierarchy from **Collection** to **List** . I will show an example of using two different overloaded versions of the **add** method to add new elements to an **ArrayList** object. One version is declared in the **Collection** interface and both versions are declared in the **List** interface.

3.4.13.3.3 To cast, or not to cast

I will illustrate the use of a *cast* to change the type of a reference from **Collection** to **List** , in order to call a version of the **add** method that is declared only in the **List** interface.

This version of the program, (*in which the **add** method actually does an insert*) makes it possible for the user to control the location of each individual element added to a **List** . The fact that the location of each element can be controlled in a **List** is what causes a **List** to be an *ordered* collection.

I will illustrate that a cast is not required on a reference being treated as type **Collection** in order to call the version of the **add** method that is declared in the **Collection** interface. This version of the **add** method supports the addition of new elements only at the end of the **List** .

3.4.13.3.4 Comparable interface not required for a List

Finally, I will show that it is not necessary for objects to implement the **Comparable** interface to make them eligible for inclusion in a **List** . I will tell you that it is necessary for objects to implement the **Comparable** interface to make them eligible for inclusion in a **SortedSet** , although I won't demonstrate that in this module.

3.4.13.4 Discussion and sample code

3.4.13.4.1 We will begin with a quiz

Let's begin with a quiz to test your prior knowledge of the Collections Framework.

What output is produced by the program shown in Listing 1 (p. 1005) ?

- A. Compiler Error
- B. Runtime Error
- C. 44321
- D. 4321
- E. 1234
- F. 12344
- G. None of the above.

Listing 1 . The program named Comparable01.

```
//File Comparable01.java

import java.util.*;

public class Comparable01{
    public static void main(String args[]){
        new Worker().doIt();
    }//end main()
}//end class Comparable01

class Worker{
    public void doIt(){
        Iterator iter;
        Collection ref;

        ref = new ArrayList();
        Populator.fillIt(ref);
        iter = ref.iterator();
        while(iter.hasNext()){
            System.out.print(iter.next());
        }//end while loop
        System.out.println();
    }//end doIt()
}// end class Worker

class Populator{
    public static void fillIt(Collection ref){
        ref.add(0,new MyClass(4));
        ref.add(1,new MyClass(4));
        ref.add(2,new MyClass(3));
        ref.add(3,new MyClass(2));
        ref.add(4,new MyClass(1));
    }//end fillIt()
}//end class Populator

class MyClass{
    int data;

    MyClass(){
        data = 0;
    }//end noarg constructor

    MyClass(int data){
        this.data = data;
    }//end parameterized constructor

    public String toString(){
        return "" + data;
    }//end overridden toString()
}

}//end MyClass Available for free at Connexions <http://cnx.org/content/col11441/1.206>
```

Table 3.378

If your answer was **A. Compiler Error** , you were correct.

3.4.13.4.1.1 What caused the compiler error?

The compiler error was caused by the code shown in Listing 2 (p. 1006) .

Listing 2 . The code with the problem.

```
public static void fillIt(Collection ref){
    ref.add(0,new MyClass(4));
}
```

Table 3.379

The problem here is that the method named **fillIt** receives a reference to an object of the **ArrayList** class as the interface type **Collection** , and attempts to call the following overloaded method on that reference:

add(int index, Object element)

However, the **Collection** interface knows nothing about a method having that signature.

3.4.13.4.1.2 Implements Collection and List

The **ArrayList** class implements both the **Collection** interface and the **List** interface. As you may recall from earlier modules in this series, **List** is a sub-interface of **Collection** . The **List** interface declares the following overloaded versions of the **add** method:

- **add(Object o)**
- **add(int index, Object element)**

The second of these two methods, which is called in Listing 2 (p. 1006) , is unknown to the **Collection** interface. The **Collection** interface declares only the first version of the **add** method shown above.

3.4.13.4.1.3 Specialization

This is the result of specialization. A **List** object is a more-specialized collection than a **Collection** object.

Therefore, the version of the **add** method that requires two parameter cannot be called on a reference to an **ArrayList** object when that object is treated as the generic type **Collection** .

3.4.13.4.2 Modified program

Now, take a look at the modified version of the program as shown in Listing 3 (p. 1008) .

What output is produced by the program shown in Listing 3 (p. 1008) ?

- A. Compiler Error
- B. Runtime Error
- C. 44321
- D. 4321
- E. 1234
- F. 12344

- G. 443521
- H. None of the above.

Listing 3 . The program named Comparable02.

```

//File Comparable02.java

import java.util.*;

public class Comparable02{
    public static void main(String args[]){
        new Worker().doIt();
    }//end main()
}//end class Comparable02

class Worker{
    public void doIt(){
        Iterator iter;
        Collection ref;

        ref = new ArrayList();
        Populator.fillIt(ref);
        iter = ref.iterator();
        while(iter.hasNext()){
            System.out.print(iter.next());
        }//end while loop
        System.out.println();
    }//end doIt()
}// end class Worker

class Populator{
    public static void fillIt(Collection ref){
        ((List)ref).add(0,new MyClass(4));
        ((List)ref).add(1,new MyClass(4));
        ((List)ref).add(2,new MyClass(3));
        ((List)ref).add(3,new MyClass(2));
        ((List)ref).add(4,new MyClass(1));
        ((List)ref).add(3,new MyClass(5));
    }//end fillIt()
}//end class populator

class MyClass{
    int data;

    MyClass(){
        data = 0;
    }//end noarg constructor

    MyClass(int data){
        this.data = data;
    }//end parameterized constructor

    public String toString(){
        return "" + data;
    }//end overridden toString()
}

}//end MyClass

```

Table 3.380

If your answer was **G. 443521** , you are correct.

3.4.13.4.2.1 The corrected code

This version of the program illustrates a mechanism for correcting the problem in the earlier program shown in Listing 1 (p. 1005) . The updated code that corrected the problem is shown in Listing 4 (p. 1009) .

Listing 4 . The corrected code.

```
class Populator{
public static void fillIt(Collection ref){
    ((List)ref).add(0,new MyClass(4));
    ((List)ref).add(1,new MyClass(4));
    ((List)ref).add(2,new MyClass(3));
    ((List)ref).add(3,new MyClass(2));
    ((List)ref).add(4,new MyClass(1));
    ((List)ref).add(3,new MyClass(5));
} //end fillIt()
} //end class populator
```

Table 3.381

The incoming parameter to the **fillIt** method in Listing 4 (p. 1009) is a reference to an object instantiated from the **ArrayList** class. That reference is passed to the **fillIt** method as type **Collection** , which is legal because the **ArrayList** class implements both the **Collection** interface and the **List** interface.

3.4.13.4.2.2 Casting to type List

The code in Listing 4 (p. 1009) uses a cast to temporarily convert the incoming reference from type **Collection** to type **List** . Because the version of the **add** method that is used in Listing 4 (p. 1009) is declared in the **List** interface, and because the **ArrayList** class correctly implements the **List** interface, that version of the **add** method can be called on the reference to the **ArrayList** object when it is treated as the interface type **List** . Hopefully this is review material for you at this point. If not, you may need to go back and study some of my earlier modules.

3.4.13.4.3 The List contract for the add method

Listing 4 (p. 1009) also illustrates part of the contract for this version of the **add** method in the **List** interface. This version of the **add** method makes it possible to specify the position of each element added to the **ArrayList** object.

(A List is an ordered collection because the user has control over the location of each element in the collection relative to the other elements in the collection.)

3.4.13.4.3.1 Controlling the locations of the elements

In Listing 4 (p. 1009) , the elements are added to the **ArrayList** object in increasing element order during the first five invocations of the **add** method. However, the sixth invocation of the **add** method adds a new element at index position 3.

3.4.13.4.3.2 Add method actually does an insert

A portion of the contract for this version of the `add` method in the `List` interface is as follows:

"Inserts the specified element at the specified position in this list (optional operation). Shifts the element currently at that position (if any) and any subsequent elements to the right (adds one to their indices)."

Thus, the new element is inserted at that position, and the other elements are pushed up, as required, toward higher index values to make room for the new element.

3.4.13.4.4 The Vector class

Here is an interesting side note. The Java `Vector` class has been around longer than the Collections Framework. Somewhere along the way, the `Vector` class was upgraded to cause it to become a concrete implementation of the `Collection` interface and the `List` interface.

As a result of the upgrade, the `Vector` class now provides an implementation of the `add` method described above. Except for the order of the parameters, that `add` method appears to have the same behavior as the older method named:

`insertElementAt(Object elem, int index)`

You can insert elements into a `Vector` object by calling the `add` method on that object while treating it as type `List`. However, since the older `insertElementAt` method is not declared in the `List` interface, you cannot insert an element into the `Vector` object by calling the `insertElementAt` method while treating it as a `List`. In order to call that method, you must treat it as type `Vector`.

3.4.13.4.5 More on the List contract

Another portion of the contract for a `List` object is that the `iterator` method

"Returns an iterator over the elements in this list in proper sequence."

As a result, the code shown in Listing 5 (p. 1010), along with the overridden `toString` method of the `MyClass` class causes the program to display the elements in the following order:

`443521` .

Listing 5 . Display using an iterator.
<pre> iter = ref.iterator(); while(iter.hasNext()){ System.out.print(iter.next()); } //end while loop </pre>

Table 3.382

3.4.13.4.6 Duplicates are allowed in a List

One final thing that is worthy of note in this program is that a `List` objects allows duplicates. Hence, the populated collection contains references to two separate objects that are equal to one another in the sense that they both contain the same values in their instance variables.

3.4.13.4.7 One more sample program

Let's take a look at one more sample program. What output is produced by the program shown in Listing 6 (p. 1012) ?

- A. Compiler Error
- B. Runtime Error
- C. 44321
- D. 4321
- E. 1234
- F. 12344
- G. None of the above.

Listing 6 . The program named Comparable03.

```

//File Comparable03.java

import java.util.*;

public class Comparable03{
    public static void main(String args[]){
        new Worker().doIt();
    }//end main()
}//end class Comparable03

class Worker{
    public void doIt(){
        Iterator iter;
        Collection ref;

        ref = new ArrayList();
        Populator.fillIt(ref);
        iter = ref.iterator();
        while(iter.hasNext()){
            System.out.print(iter.next());
        }//end while loop
        System.out.println();
    }//end doIt()
}// end class Worker

class Populator{
    public static void fillIt(Collection ref){
        ref.add(new MyClass(4));
        ref.add(new MyClass(4));
        ref.add(new MyClass(3));
        ref.add(new MyClass(2));
        ref.add(new MyClass(1));
    }//end fillIt()
}//end class populator

class MyClass{
    int data;

    MyClass(){
        data = 0;
    }//end noarg constructor

    MyClass(int data){
        this.data = data;
    }//end parameterized constructor

    public String toString(){
        return "" + data;
    }//end overridden toString()
}

}//end MyClass

```

Available for free at Connexions <<http://cnx.org/content/col11441/1.206>>

Table 3.383

If you selected **C. 44321** , you are correct.

3.4.13.4.7.1 No need to cast to type List

As shown in Listing 7 (p. 1013) , this program takes a different approach to solving the problem originally exposed in the program shown in Listing 1 (p. 1005) .

Listing 7 . No need to cast to type List.

```

class Populator{
public static void fillIt(
                Collection ref){
    ref.add(new MyClass(4));
    ref.add(new MyClass(4));
    ref.add(new MyClass(3));
    ref.add(new MyClass(2));
    ref.add(new MyClass(1));
} //end fillIt()
} //end class populator

```

Table 3.384

This program does not change the type of the incoming reference to the **ArrayList** object in the **fillIt** method. Rather, it continues to treat the incoming reference as type **Collection** , and calls the version of the **add** method that is declared in the **Collection** interface. This avoids the requirement to cast the incoming reference to type **List** .

The contract for this version of the **add** method in the **List** interface is

"Appends the specified element to the end of this list (optional operation)."

As a result, the new elements are added to the collection in increasing index order. Since an iterator on a **List** returns the elements in increasing index order, this program displays the elements in the same order that they are added.

3.4.13.4.8 What happened to the Comparable interface?

By now, you are probably wondering what all of this has to do with the **Comparable** interface, because I haven't mentioned that interface since the introductory comments at the beginning of the module.

3.4.13.4.8.1 Comparable interface is not required for a List

Actually, the purpose of this module is to illustrate *the lack of* any requirement to make use of the **Comparable** interface with **List** objects. In particular, the purpose is to illustrate that this is one of the features that differentiates between a **List** object and a **Set** or **SortedSet** object.

A **List** can be used as a container for other objects regardless of whether or not those objects implement the **Comparable** interface. However, in the next module, we will see that objects must implement the **Comparable** interface in order to be eligible for inclusion in collections that implement the **SortedSet** interface.

This and the next several modules are intended to provide you with an understanding of the interaction between the **Comparable** interface, the **Comparator** interface, and the Collections Framework.

3.4.13.4.8.2 No requirement to compare

Because a **List** makes no attempt to eliminate duplicate elements, or to sort the elements on the basis of their values, there is no requirement to *compare* objects when placing them in a **List** . Therefore, objects whose references are stored in a **List** are not required to implement the **Comparable** interface (*but they may implement the Comparable interface without causing any harm*) .

3.4.13.4.8.3 Comparison is required for a SortedSet

Because a **SortedSet** does eliminate duplicates and does sort the elements on the basis of their values, there is a requirement to *compare* each new element with the existing elements in a **SortedSet** whenever a new element is added to the collection. Therefore, objects whose references are stored in a **SortedSet** are required to implement the **Comparable** interface.

3.4.13.5 Run the program

I encourage you to copy the code from Listing 1 (p. 1005) , Listing 3 (p. 1008) , and Listing 6 (p. 1012) . Paste the code into your Java editor. Then compile and execute it.

Run the program and observe the results. Experiment with the code. Make changes, run the program again, and observe the results of your changes. Make certain that you can explain why your changes behave as they do.

3.4.13.6 Summary

In this module, I began discussing the interaction between the **Comparable** interface and the Collections Framework.

I provided a concrete example of the specialization that occurs when moving down the interface hierarchy from **Collection** to **List** . I showed an example of using two different overloaded versions of the **add** method to add new elements to an **ArrayList** object. One version is declared in the **Collection** interface and both versions are declared in the **List** interface.

I illustrated the use of a *cast* to change the type of a reference from **Collection** to **List** , in order to call a version of the **add** method that is declared only in the **List** interface. This version makes it possible for the user to control the location of each individual element added to a **List** .

I illustrated that a cast is not required on a reference being treated as type **Collection** in order to call the version of the **add** method that is declared in the **Collection** interface. This version of the **add** method supports the addition of new elements only at the end of the **List** .

Finally, I explained that it is not necessary for objects to implement the **Comparable** interface to make them eligible for inclusion in a **List** .

Although I didn't demonstrate it, I told you that it is necessary for objects to implement the **Comparable** interface to make them eligible for inclusion in a **SortedSet** .

3.4.13.7 What's next?

The next module will begin exploring the interaction between the **Comparable** interface and the **SortedSet** interface of the *Collections Framework*.

3.4.14.3.11 Question 11

True or False? Because a **List** makes no attempt to eliminate duplicate elements, or to sort the elements on the basis of their values, there is no requirement to *compare* objects when placing them in a **List** . Therefore, objects whose references are stored in a **List** are not required to implement the **Comparable** interface (*but they may implement the Comparable interface without causing any harm*) .

Answer 11 (p. 1020)

3.4.14.3.12 Question 12

True or False? Because a **SortedSet** does eliminate duplicates and does sort the elements on the basis of their values, there is a requirement to *compare* each new element with the existing elements in a **SortedSet** whenever a new element is added to the collection. Therefore, objects whose references are stored in a **SortedSet** are required to implement the **Comparable** interface.

3.4.14.5.8 Answer 5

False. The **List** interface declares the following overloaded versions of the **add** method but the **Collection** interface declares only the first one of the two.

- **add(Object o)**
- **add(int index, Object element)**

Back to Question 5 (p. 1017)

3.4.14.5.9 Answer 4

Compiler Error. The method named **fillIt** receives a reference to an object of the **ArrayList** class as the interface type **Collection**, and attempts to call the following overloaded method on that reference:

add(int index, Object element)

However, the **Collection** interface knows nothing about a method having that signature.

3.4.15.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java Collections framework in particular.

This module explains why the elements stored in a **TreeSet** collection must be references to objects instantiated from a class that implements the **Comparable** interface. The module also briefly discusses an alternative approach using the **Comparator** interface.

The module shows you how to implement the **Comparable** interface for a new class definition, explains the "natural ordering of the elements" for a class, and discusses the "consistent with equals" requirement. Finally, the module shows you how to define a new class whose objects are eligible for inclusion in a **TreeSet** collection.

In addition to studying these modules, I strongly recommend that you study the Collections Trail ⁴⁸⁹ in Oracle's Java Tutorials ⁴⁹⁰. The modules in this collection are intended to supplement and not to replace those tutorials.

3.4.15.3 Preview

In this module, I will teach you why the elements stored in a `TreeSet` collection must be references to objects instantiated from a class that implements the `Comparable` interface. (*In a subsequent module, I will teach you about an alternative approach that makes use of the `Comparator` interface.*)

I will provide an example of implementing the `Comparable` interface for a new class definition, and will teach you about the *natural ordering of the elements* for a class.

I will teach you the meaning of the *consistent with equals* requirement and show you how to satisfy that requirement for a new class definition.

Finally, I will show you how to define a new class whose objects are eligible for inclusion in a `TreeSet` collection.

3.4.15.4 Discussion and sample code

3.4.15.4.1 Generics

The code in this module is written with no thought given to Generics ⁴⁹¹ . As a result, if you copy and compile this code, you will probably get a warning about *unchecked or unsafe operations* .

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.15.4.2 Begin with a quiz

Let's begin with a quiz to test your prior knowledge of the Collections Framework.

What output is produced by the program shown in Listing 1 (p. 1030) ?

- A. Compiler Error
- B. Runtime Error
- C. 44321
- D. 4321
- E. 1234
- F. 12344
- G. None of the above.

        return "" + data;
    }//end overridden toString()
} //end MyClass

```

Table 3.388

If your answer was **B. Runtime Error** , you were correct.

3.4.15.4.2.1 What caused the runtime error?

The runtime error was caused by the code shown in Listing 2 (p. 1031) .

Listing 2 . The code with the problem.

```
class Populator{
public static void fillIt(Collection ref){
    ref.add(new MyClass(4));
}
```

Table 3.389

3.4.15.4.2.2 Why did this code produce a runtime error?

This code produced a runtime error for the following reasons.

The incoming parameter of the `fillIt` method is a reference to an object of type `TreeSet` but it is received as type `Collection` . The `TreeSet` class implements the `Collection` , `Set` , and `SortedSet` interfaces. (*In this module, we will be primarily interested in the `Set` and `SortedSet` interfaces.*)

The contract for the `add` method of the `Set` interface reads partially as follows:

"Adds the specified element to this set if it is not already present ... If this set already contains the specified element, the call leaves this set unchanged and returns false. ... this ensures that sets never contain duplicate elements."

3.4.15.4.2.3 What does this mean?

This means that whenever the `add` method is called on a `Set` object, the `add` method must have a way of determining if the element being added is a duplicate of an element that already exists in the collection. This means that it must be possible for the `add` method to *compare* the new element with all of the existing elements to determine if the new element is a duplicate of any of the existing elements.

3.4.15.4.2.4 The `compareTo` method

The documentation for the `TreeSet` class states the following:

"... the `Set` interface is defined in terms of the equals operation, but a `TreeSet` instance performs all key comparisons using its `compareTo` (or `compare`) method ..."

What this means is that insofar as the handling of duplicate elements is concerned, (*with the possible exception given below involving a `Comparator`*), in order for a reference to an object to be included in a `TreeSet` collection, the class from which that object is instantiated must implement the `Comparable` interface.

3.4.15.4.2.5 A possible exception

Note that one of the constructors for the **TreeSet** class makes it possible to instantiate a new object by passing a parameter that is a reference to an object that implements the **Comparator** interface.

The **Comparator** interface declares a method named **compare**, which compares its two arguments for order. The text in the above excerpt from the Oracle documentation suggests that when this parameterized constructor is used, it may not be necessary for the objects included in the **TreeSet** collection to implement the **Comparable** interface.

I won't discuss that possibility in this module, but I will discuss it in a future module that discusses the use of the **Comparator** interface. For purposes of this module, I will concentrate on the use of a **TreeSet** collection that does not receive a reference to a **Comparator** object when it is instantiated.

3.4.15.4.2.6 The SortedSet interface

The **TreeSet** class also implements the **SortedSet** interface. The documentation for the **SortedSet** interface states the following:

*"A set that further guarantees that its iterator will traverse the set in ascending element order, sorted according to the natural ordering of its elements (see **Comparable**), or by a **Comparator** provided at sorted set creation time."*

3.4.15.4.2.7 Natural ordering of the elements

The key term to note in the above quotation is the term *natural ordering of its elements*. This takes us back to the **Comparable** interface, for which the documentation states:

*"This interface imposes a total ordering on the objects of each class that implements it. This ordering is referred to as the class's natural ordering, and the class's **compareTo** method is referred to as its natural comparison method."*

3.4.15.4.2.8 Conclusion regarding traversal

The conclusion is, in order for the iterator to be able to traverse the set according to the *natural ordering of its elements*, the elements stored in an object that implements the **SortedSet** interface must be instantiated from a class that implements the **Comparable** interface (*unless a **Comparator** is provided when the **SortedSet** object is instantiated.*)

3.4.15.4.2.9 The bottom line

The bottom line is, because the class named **MyClass** in Listing 1 (p. 1030) does not implement the **Comparable** interface, objects of that class are not eligible for use with a **TreeSet** collection (*unless a **Comparator** is provided when the **TreeSet** object is instantiated.*)

A **Comparator** was not provided when the **TreeSet** object was instantiated in Listing 1 (p. 1030). Therefore, the attempt in Listing 2 (p. 1031), to add a **MyClass** object to the **TreeSet** collection resulted in a **ClassCastException** being thrown at runtime. The runtime error reads partially as follows:

"Exception ... java.lang.ClassCastException: MyClass cannot be cast to java.lang.Comparable"

3.4.15.4.3 The solution

To solve this problem, we must modify the definition of the class named **MyClass** to make it implement the **Comparable** interface (*assuming that we don't provide a **Comparator** when the **TreeSet** object is instantiated*).

This is accomplished in the modified version of the program shown in Listing 3 (p. 1034) .

Listing 3 . The program named Comparable05.

```

//File Comparable05.java
import java.util.*;

public class Comparable05{
    public static void main(String args[]){
        new Worker().doIt();
    }//end main()
} //end class Comparable05

class Worker{
    public void doIt(){
        Iterator iter;
        Collection ref;

        ref = new TreeSet();
        Populator.fillIt(ref);
        iter = ref.iterator();
        while(iter.hasNext()){
            System.out.print(iter.next());
        } //end while loop
        System.out.println();

    } //end doIt()
} // end class Worker

class Populator{
    public static void fillIt(Collection ref){
        ref.add(new MyClass(4));
        ref.add(new MyClass(4));
        ref.add(new MyClass(3));
        ref.add(new MyClass(2));
        ref.add(new MyClass(1));
    } //end fillIt()
} //end class Populator

class MyClass implements Comparable{
    int data;

    MyClass(){
        data = 0;
    } //end noarg constructor

    MyClass(int data){
        this.data = data;
    } //end parameterized constructor

    public String toString(){
        return "" + data;
    } //end overridden toString()

    public int compareTo(Object o){
        if(!(o instanceof MyClass))
            throw new ClassCastException();
        if(((MyClass)o).data < data)

```

Table 3.390

3.4.15.4.3.1 The corrected code

The important code to note in this modified version of the program is the new definition of the class named **MyClass** . The other code in the program is essentially the same as in the previous version of the program.

The beginning portion of the new definition for **MyClass** is shown in Listing 4 (p. 1035) .

Listing 4 . Beginning of the class named **MyClass**.

```
class MyClass implements Comparable{
int data;

MyClass(){
    data = 0;
} //end noarg constructor

MyClass(int data){
    this.data = data;
} //end parameterized constructor

public String toString(){
    return "" + data;
} //end overridden toString()
```

Table 3.391

The code shown in Listing 4 (p. 1035) is identical to the code in the previous version with one major exception. This version of the class definition implements the **Comparable** interface. That means that this class must provide a concrete definition for the following method, which is the only method declared in the **Comparable** interface:

```
public int compareTo(Object o)
```

3.4.15.4.3.2 The compareTo method

The description of the **compareTo** method in the Oracle documentation begins as follows:

"Compares this object with the specified object for order. Returns a negative integer, zero, or a positive integer as this object is less than, equal to, or greater than the specified object."

Beyond this, there are a number of additional stipulations that I won't repeat here. You can view them in the Oracle documentation if you are interested in that level of detail.

Listing 5 (p. 1036) shows my implementation of the **compareTo** method. Although this implementation satisfies the general description given above, I haven't taken the time to test it fully to confirm that it meets all of the additional stipulations provided by Oracle.

Listing 5 . The compareTo method.

```

    public int compareTo(Object o){
    if(!(o instanceof MyClass))
        throw new ClassCastException();
    if(((MyClass)o).data < data)
        return 1;
    if(((MyClass)o).data > data)
        return -1;
    else return 0;
    }//end compareTo()

```

Table 3.392**3.4.15.4.3.3 Consistent with equals**

The Oracle documentation strongly emphasizes the need to make certain that a class' natural ordering is *consistent with equals*, and provides the rules for meeting that requirement.

Further, the documentation for the **TreeSet** class reads partially as follows:

*"Note that the ordering maintained by a set (whether or not an explicit comparator is provided) must be **consistent with equals** if it is to correctly implement the Set interface. ..."*

3.4.15.4.3.4 Meeting the consistent with equals requirement

In order to satisfy the rules and to cause the *natural ordering* of the **MyClass** class to be *consistent with equals*, it was necessary to override the **equals** method inherited from the **Object** class. My overridden version of the **equals** method is shown in Listing 6 (p. 1036).

Listing 6 . The overridden equals method.

```

    public boolean equals(Object o){
    if(!(o instanceof MyClass))
        return false;
    if(((MyClass)o).data == data)
        return true;
    else return false;
    }//end overridden equals()
} //end MyClass

```

Table 3.393

As was the case in defining the **compareTo** method, there are also a large number of stipulations involved in properly overriding the **equals** method. I will simply refer you to the Oracle documentation if you are interested in reading about those stipulations.

3.4.15.4.3.5 The program output

Given all of the above, this program compiles and executes correctly, producing the following output.

1234

Note that duplicate elements were eliminated, and the iterator traversed the set in ascending element order, sorted according to the natural ordering of the elements, as required for a **SortedSet** collection.

3.4.15.5 Run the program

I encourage you to copy the code from Listing 1 (p. 1030) and Listing 3 (p. 1034) . Paste the code into your Java editor. Then compile and execute it.

Run the program and observe the results. Experiment with the code. Make changes, run the program again, and observe the results of your changes. Make certain that you can explain why your changes behave as they do.

3.4.15.6 Summary

I explained why the elements stored in a **TreeSet** collection must be references to objects instantiated from a class that implements the **Comparable** interface. (*In a future module, I will teach you about an alternative approach that makes use of the **Comparator** interface.*)

I provided an example of implementing the **Comparable** interface for a new class definition, and I taught you about the *natural ordering of the elements* for a class.

I taught you the meaning of the *consistent with equals* requirement and showed you how to satisfy that requirement for a new class definition.

I showed you how to define a new class whose objects are eligible for inclusion in a **TreeSet** collection.

3.4.15.7 What's next?

In the next module, I will discuss the use of the **Comparator** interface in order to achieve a sorting order that is different from the *natural ordering* of the elements in a sorted collection.

3.4.17.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java Collections framework in particular.

This module discusses and illustrates the use of the **`Comparator`** interface. The sorting order established by a **`Comparator`** may be different or may be the same as the natural order. A **`Comparator`** can be used to establish a sorting order for objects that don't have a natural ordering. The use of a **`Comparator`** is an alternative to the implementation of the **`Comparable`** interface.

This module is also the first of several modules on the **`Comparator`** interface. The purpose of the modules in this group is to teach you about the interactions between the **`Comparator`** interface and the Collections Framework, particularly with respect to the **`Set`**, **`SortedSet`**, and **`SortedMap`** interfaces of the Collections Framework. This module discusses **`Set`** and **`SortedSet`**. A discussion of **`SortedMap`** will be deferred to a future module.

In addition to studying these modules, I strongly recommend that you study the Collections Trail⁴⁹⁹ in Oracle's Java Tutorials⁵⁰⁰. The modules in this collection are intended to supplement and not to replace those tutorials.

3.4.17.3 Preview

Previous modules have discussed the use of the **Comparable** interface. This module discusses and illustrates the use of the **Comparator** interface.

The **Comparable** interface establishes *natural ordering*. The sorting order established by a **Comparator** may be different or may be the same as the *natural order*.

A **Comparator** can be used to establish a sorting order for objects that don't have a *natural ordering*.

The use of a **Comparator** is an alternative to the implementation of the **Comparable** interface. For example, a **TreeSet** object instantiated with the benefit of a **Comparator** object doesn't require the objects in its collection to implement **Comparable**.

3.4.17.4 Discussion and sample code

3.4.17.4.1 Generics

The code in this module is written with no thought given to Generics⁵⁰¹. As a result, if you copy and compile this code, you will probably get a warning about *unchecked or unsafe operations*.

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.17.4.2 The Comparable interface

Previous modules have discussed the use of the **Comparable** interface to establish the *natural ordering* of elements in a sorted set. Although the name of the **Comparable** interface is similar to the name of the **Comparator** interface, they are different interfaces. Don't be confused by the similarity of the names.

3.4.17.4.3 The Comparator interface

This module will begin the discussion of an alternative approach to sorting, using the **Comparator** interface to establish sorting order. The discussion will be continued in future modules.

The sorting order established by a **Comparator** may be different from the *natural ordering*. The **Comparator** interface can also be used to establish sorting order for objects that do not implement the **Comparable** interface and therefore do not have a *natural ordering*.

3.4.17.4.4 Beginning with a quiz

Let's begin with a little quiz to test your prior knowledge of the Collections Framework.

What output is produced by the program shown in Listing 1 (p. 1050) ?

- A. Compiler Error
- B. Runtime Error
- C. 44321
- D. 4321
- E. 1234
- F. 12344
- G. None of the above.

Listing 1 . The program named Comparator02.

//Copyright 2001, R.G.Baldwin
import java.util.*;
import java.io.Serializable;

public class Comparator02{
    public static void main(String args[]){
        new Worker().doIt();
    }//end main()
}//end class Comparator02

class Worker{
    public void doIt(){
        Iterator iter;
        Collection ref;

        ref = new TreeSet(new TheComparator());
        Populator.fillIt(ref);
        iter = ref.iterator();
        while(iter.hasNext()){
            System.out.print(iter.next());
        }//end while loop
        System.out.println();

    }//end doIt()
}// end class Worker

class Populator{
    public static void fillIt(Collection ref){
        ref.add(new MyClass(4));
        ref.add(new MyClass(4));
        ref.add(new MyClass(3));
        ref.add(new MyClass(2));
        ref.add(new MyClass(1));
    }//end fillIt()
}//end class Populator

class MyClass{
    int data;

    MyClass(){
        data = 0;
    }//end noarg constructor

    MyClass(int data){
        this.data = data;
    }//end parameterized constructor

    public String toString(){
        return "" + data;
    }//end overridden toString()
}

} //end MyClass

```

Table 3.396

If your answer was **E. 1234** , then you are correct.

3.4.17.4.5 Eligibility for inclusion in a `TreeSet`

The `TreeSet` class implements the `SortedSet` interface.

In an earlier module, I told you that in order to be eligible for inclusion in a `TreeSet` collection, an object must be instantiated from a class that implements the `Comparable` interface.

At that time, I also told you that it is possible to instantiate a new `TreeSet` object using a constructor that receives an incoming reference to a `Comparator` object, in which case it is not necessary for the objects in the collection to implement the `Comparable` interface.

3.4.17.4.5.1 Using a `Comparator` object

The program in Listing 1 (p. 1050) takes this latter approach. The main purpose of this program is to illustrate the use of a `Comparator` object as an alternative to implementation of the `Comparable` interface.

3.4.17.4.5.2 Passing `Comparator` to `TreeSet` constructor

The code fragment in Listing 2 (p. 1051) shows the instantiation of a new `TreeSet` object, passing an anonymous object of type `TheComparator` as a parameter to the constructor for `TreeSet` . Shortly, we will see that the class named `TheComparator` implements the `Comparator` interface. Therefore, an object instantiated from that class is a `Comparator` object.

Listing 2 . Passing `Comparator` to `TreeSet` constructor.

```
Collection ref;
ref = new TreeSet(new TheComparator());
Populator.fillIt(ref);
```

Table 3.397

3.4.17.4.5.3 Passing the `TreeSet` to a `Populator` method

The code fragment in Listing 2 (p. 1051) also shows the reference to the `TreeSet` object being stored in a reference variable of the interface type `Collection` . The reference to the `TreeSet` object is passed as type `Collection` to a method named `fillIt` .

The purpose of the `fillIt` method is to instantiate some objects of type `MyClass` , and to store those object references in the `TreeSet` collection.

3.4.17.4.5.4 The `fillIt` method

The code fragment in Listing 3 (p. 1052) shows the entire method named `fillIt` . This method instantiates five objects from the class named `MyClass` and adds those object's references to the `TreeSet` collection.

Listing 3 . The fillIt method.

```

class Populator{
public static void fillIt(Collection ref){
    ref.add(new MyClass(4));
    ref.add(new MyClass(4));
    ref.add(new MyClass(3));
    ref.add(new MyClass(2));
    ref.add(new MyClass(1));
} //end fillIt()
} //end class Populator

```

Table 3.398**3.4.17.4.5.5 Similar to previous program**

This is essentially the same code that we saw in a sample program in a previous module. In that module, we saw that it was necessary for the class named **MyClass** to implement the **Comparable** interface. Otherwise, the **add** method would throw a runtime exception.

3.4.17.4.5.6 MyClass does not implement Comparable

In that program, however, the **TreeSet** object was instantiated without benefit of a **Comparator** object.

As you can see in the code fragment in Listing 4 (p. 1053) , the class named **MyClass** in this program does not implement the **Comparable** interface.

3.4.17.4.5.7 Comparator eliminates requirement for Comparable

Furthermore, the **add** method in Listing 3 (p. 1052) does not throw a runtime exception. That is because the **TreeSet** object was instantiated with the benefit of a **Comparator** object.

The use of a **Comparator** object in the instantiation of the **TreeSet** object eliminates the requirement for objects stored in the **TreeSet** collection to implement the **Comparable** interface.

Listing 4 . The class named MyClass.

```

class MyClass{
int data;

MyClass(){
    data = 0;
} //end noarg constructor

MyClass(int data){
    this.data = data;
} //end parameterized constructor

public String toString(){
    return "" + data;
} //end overridden toString()
} //end MyClass

```

Table 3.399**3.4.17.4.6 The class named TheComparator**

That brings us to the class named **TheComparator** from which the **Comparator** object was instantiated and passed to the constructor for the **TreeSet** object in Listing 2 (p. 1051) . The declaration for the class named **TheComparator** is shown in Listing 5 (p. 1053) .

Listing 5 . Beginning of the class named TheComparator.

```

class TheComparator
implements Comparator,Serializable{

```

Table 3.400

As you can see, the class named **TheComparator** implements both the **Comparator** interface and the **Serializable** interface.

3.4.17.4.6.1 Implementing the Comparator interface

By implementing the **Comparator** interface, an object instantiated from the class is eligible to be passed to the constructor for a **TreeSet** object, which requires an incoming parameter of type **Comparator** .

3.4.17.4.6.2 Implementing the Serializable interface

Here is what Oracle has to say about implementing the **Serializable** interface:

"Note: It is generally a good idea for comparators to implement java.io.Serializable, as they may be used as ordering methods in serializable data structures (like TreeSet, TreeMap). In order for the data structure to serialize successfully, the comparator (if provided) must implement Serializable."

Since the **Serializable** interface doesn't declare any methods, implementing the interface simply requires a declaration that the interface is being implemented.

3.4.17.4.6.3 Methods of the Comparator interface

The **Comparator** interface declares the two methods listed below:

- public int **compare** (Object o1, Object o2)
- public boolean **equals** (Object obj)

As is always the case when implementing interfaces, a class that implements the **Comparator** interface must provide concrete definitions for both of these methods.

3.4.17.4.6.4 The compare method

The beginning of the **compare** method is shown in Listing 6 (p. 1054) .

Listing 6 . Beginning of the compare method.

```
public int compare(Object o1, Object o2){
    if(!(o1 instanceof MyClass))
        throw new ClassCastException();
    if(!(o2 instanceof MyClass))
        throw new ClassCastException();
```

Table 3.401

The purpose of a **Comparator** is to compare the values stored in the instance variables of two objects and to return a value indicating which object is *greater* .

3.4.17.4.7 Specialization is required

Generally speaking, therefore, a **Comparator** object must be specialized to deal with a particular type of object. That type could be

- A specific class from which the object is instantiated,
- A specific interface implemented by the class from which the object is instantiated, or perhaps
- A specific superclass of the class from which the object is instantiated.

The code in Listing 6 (p. 1054) confirms that both of the objects to be compared are of the correct type, which in this case is type **MyClass** .

3.4.17.4.7.1 Must gain access to instance variables

Regardless of how the type is established, the code in the **compare** method of the **Comparator** object must gain access to the instance variables of the two objects passed to the **compare** method as type **Object** . This normally requires that a downcast be performed on the incoming object references.

3.4.17.4.7.2 Specialized for type MyClass

This **Comparator** is specialized to compare two objects of the class named **MyClass** . The first two statements in Listing 6 (p. 1054) above confirm that both of the incoming objects are of type **MyClass** . If either object is not of that type, an exception is thrown.

3.4.17.4.7.3 General behavior of compare method

The general description of the behavior of the **compare** method as provided by Oracle is shown below:

"Compares its two arguments for order. Returns a negative integer, zero, or a positive integer as the first argument is less than, equal to, or greater than the second."

3.4.17.4.7.4 Implementation of required behavior

This behavior is accomplished by the code shown in Listing 7 (p. 1055) . In this case, the comparison is based solely on the values of the instance variable named **data** in each of the two objects.

Depending on which object contains the larger value in its instance variable, a value of 1 or -1 is returned. If the two values are equal, a value of 0 is returned.

*(Note that it is up to the author of the **compare** method to decide what constitutes larger. This gives the author of the method a great deal of control over the results of a sorting operation.)*

Listing 7 . Implementation of required behavior.

```

        if(((MyClass)o1).data < ((MyClass)o2).data)
            return -1;
        if(((MyClass)o1).data > ((MyClass)o2).data)
            return 1;
        else return 0;
    }//end compare()

```

Table 3.402

3.4.17.4.7.5 Other stipulations

The documentation for the **compare** method contains several other stipulations regarding the behavior of the method. While I believe that this version of the **compare** method meets all of those stipulations, I haven't taken the time to test it fully. Therefore, it is possible that it may not meet all of the stipulations in terms of its behavior.

3.4.17.4.8 The equals method

Every new class inherits a default version of the **equals** method from the class named **Object**. Therefore, a new class that implements the **Comparator** interface already has such a method. The new class is free to override the inherited version, or to simply make use of the inherited version. Here is what Oracle has to say on the subject:

"Note that it is always safe not to override Object.equals(Object). However, overriding this method may, in some cases, improve performance by allowing programs to determine that two distinct Comparators impose the same order."

3.4.17.4.8.1 Overridden equals method

I decided, for purposes of illustration, to go ahead and override the **equals** method. However, my overridden version, as shown in Listing 8 (p. 1056) isn't very significant. It simply confirms that an object being compared for equality to a **Comparator** object is instantiated from the same class.

Since the **Comparator** object doesn't contain any instance variables, there isn't much more to be tested for equality.

Listing 8 . The overridden equals method.

```
public boolean equals(Object o){
  if(!(o instanceof TheComparator))
    return false;
  else return true;
} //end overridden equals()
} //end class TheComparator
```

Table 3.403

3.4.17.4.9 The program output

Finally, the code shown in Listing 9 (p. 1056) uses an **Iterator** to display the contents of the populated **TreeSet** object.

Listing 9 . Display the contents of the TreeSet object.

```
iter = ref.iterator();
while(iter.hasNext()){
  System.out.print(iter.next());
} //end while loop
```

Table 3.404

The output produced by this code fragment is shown below.

1234

As you can see, the duplicate elements having the value 4 were eliminated as would be expected for a **Set** object. In addition, the **Comparator** was used to accomplish the following contract of a **SortedSet** object:

*"A set that further guarantees that its iterator will traverse the set in ascending element order, sorted according to the natural ordering of its elements (see **Comparable**), or by a **Comparator** provided at sorted set creation time."*

In this case, the sorted order was controlled by the **Comparator** object, and not by the *natural ordering* of the elements. The *natural ordering* is controlled by implementation of the **Comparable** interface, and the elements in this collection did not implement the **Comparable** interface. Therefore, objects of the class named **MyClass** do not have a natural order in this program.

However, the code in this version of the **Comparator** produced an output order that matches the ascending natural order that one might expect for objects of type **MyClass** . Future modules will show you how to design the **Comparator** object to produce different output orders, such as descending order for example.

3.4.17.5 Run the program

I encourage you to copy the code Listing 2 (p. 1051) and paste it into your Java editor. Then compile and execute it.

Run the program and observe the results. Experiment with the code. Make changes, run the program again, and observe the results of your changes. Make certain that you can explain why your changes behave as they do.

3.4.17.6 Summary

This module has discussed and illustrated the use of the **Comparator** interface.

The sorting order established by a **Comparator** may be different or may be the same as the *natural ordering* for a collection of objects .

A **Comparator** can be used to establish a sorting order for objects that don't have a *natural ordering* .

The use of a **Comparator** is an alternative to the implementation of the **Comparable** interface.

A **TreeSet** object instantiated with the benefit of a **Comparator** object doesn't require the objects in its collection to implement **Comparable** .

3.4.17.7 What's next?

In the next module, I will illustrate the use of a **Comparator** to eliminate the effect of case when sorting **String** objects.

Answer 5 (p. 1062)

3.4.18.3.6 Question 6

True or False? It is possible to instantiate a new **TreeSet** object using a constructor that receives an incoming reference to a **Comparable** object, in which case it is not necessary for the objects in the collection to implement the **Comparator** interface.

Answer 6 (p. 1062)

3.4.18.3.7 Question 7

True or False? In Listing 1 (p. 1063) , the constructor that is called to instantiate a new **TreeSet** object receives an incoming parameter of type **Comparable** .

Answer 7 (p. 1062)

3.4.18.3.8 Question 8

True or False? When the **fillIt** method shown in Listing 1 (p. 1063) returns, the collection object referred to by **ref** will contain references to five objects of type **MyClass** with those objects encapsulating the values 4, 4, 3, 2, and 1.

Answer 8 (p. 1061)

3.4.18.3.9 Question 9

True or False? When the **fillIt** method shown in Listing 1 (p. 1063) returns, the collection object referred to by **ref** will contain references to four objects of type **MyClass** with those objects encapsulating the values 1, 2, 3, and 4 sorted into the order shown.

3.4.18.3.10 Question 10

True or False? Given: the **Comparator** interface declares the two methods listed below:

- public int compare(Object o1, Object o2)
- public boolean equals(Object obj)

(Note that the Java documentation would replace the type `Object` with the generic type `T`. However, generics are beyond the scope of this course.)

A class that implements the **Comparator** interface must provide a concrete definition for the **compare** method but providing a concrete definition for the **equals** method is optional.

Answer 10 (p. 1061)

3.4.18.3.11 Question 11

True or False? The general behavior of the **compare** method of a **Comparator** object compares its two arguments for order and returns a negative integer, zero, or a positive integer as the first argument is less than, equal to, or greater than the second.

3.4.18.5 Answers

3.4.18.5.1 Answer 11

True.

Back to Question 11 (p. 1060)

3.4.18.5.2 Answer 10

True. Every new class inherits a default version of the `equals` method from the class named `Object`. Therefore, a new class that implements the `Comparator` interface already has such a method. The new class is free to override the inherited version, or to simply make use of the inherited version.

Back to Question 10 (p. 1059)

3.4.18.5.3 Answer 9

True.

Back to Question 9 (p. 1059)

3.4.18.5.4 Answer 8

False. When the `fillIt` method shown in Listing 1 (p. 1063) returns, the collection object referred to by `ref` will contain references to four objects of type `MyClass` with those objects encapsulating the values 4, 3, 2, and 1 with no duplicates.

Back to Question 8 (p. 1059)

3.4.18.5.5 Answer 7

False. In Listing 1 (p. 1063) , the constructor that is called to instantiate a new `TreeSet` object receives an incoming parameter of type `Comparator` . Once again, don't confuse the two interfaces simply because they have similar names.

Back to Question 7 (p. 1059)

3.4.18.5.6 Answer 6

False. It is possible to instantiate a new `TreeSet` object using a constructor that receives an incoming reference to a `Comparator` object, in which case it is not necessary for the objects in the collection to implement the `Comparable` interface. Don't confuse the two interfaces.

3.4.18.5.7 Answer 5

1234

Back to Question 5 (p. 1059)

3.4.18.5.8 Answer 4

False. Although the name of the `Comparable` interface is similar to the name of the `Comparator` interface, they are different interfaces. Don't be confused by the similarity of the names.

Back to Question 4 (p. 1059)

3.4.18.5.9 Answer 3

True.

3.4.18.5.10 Answer 2

True.

3.4.19.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java Collections framework in particular.

This module shows you how to use a **Comparator** object to achieve natural (*ascending*) order on a set of names added as **String** objects to a **TreeSet** collection while ignoring the case used to write the names.

In addition to studying these modules, I strongly recommend that you study the Collections Trail ⁵⁰⁹ in Oracle's Java Tutorials ⁵¹⁰. The modules in this collection are intended to supplement and not to replace those tutorials.

3.4.19.2.1 Viewing tip

3.4.19.3 Preview

In this module, I will show you how to use a **Comparator** object to achieve a *natural ordering* of a set of names (**String** objects) added to a **TreeSet** collection while ignoring the case used to write the names. (*The natural ordering for **String** objects is ascending.*)

3.4.19.4 Discussion and sample code

3.4.19.4.1 Generics

The code in this module is written with no thought given to Generics ⁵¹¹ . As a result, if you copy and compile this code, you will probably get a warning about *unchecked or unsafe operations* .

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.19.4.2 Beginning with a quiz

Let's begin with a quiz to test your prior knowledge of the Java Collections Framework.

What output is produced by the program shown in Listing 1 (p. 1067) ?

- A. Compiler Error
- B. Runtime Error
- C. Joe Bill Tom JOE BILL TOM
- D. Tom TOM Joe JOE Bill BILL
- E. Joe Bill Tom
- F. None of the above.

Table 3.406

If your answer was **None of the above** , you are correct.

3.4.19.4.2.1 The program output

The output produced by the program shown in Listing 1 (p. 1067) is four lines long as shown below. (*Note that the bullets shown below do not appear in the actual program output.*)

- **Natural ordering**
- **BILL Bill JOE Joe TOM Tom**
- **Comparator in use**
- **Bill Joe Tom**

3.4.19.4.2.2 From the previous module

In the previous module, I introduced you to the essentials of defining and using a **Comparator** for controlling the sort order of the elements contained in a **TreeSet** collection.

In that module, I explained the difference between *natural ordering* and the *sort ordering* produced through the use of a **Comparator** object.

However, what I showed you generally replicated the *natural ordering* , and therefore, wasn't too exciting.

3.4.19.4.2.3 Doing more with a Comparator

In this and several subsequent modules, I am going to show you some of the things that you can do with a **Comparator** object. By using a **Comparator** object, you can achieve comparisons and sort orders that are different from the *natural ordering* for a given element type.

3.4.19.4.3 Two steps in the program

The program shown in Listing 1 (p. 1067) goes through two major steps.

3.4.19.4.3.1 The first step

First it populates a **TreeSet** collection with the names of six people without using a **Comparator** . Then it displays the contents of that collection using an iterator. That produces the following output (*without the bullets*) :

- **Natural ordering**
- **BILL Bill JOE Joe TOM Tom**

As you will see later, the names were added to the collection in a different order than the output order shown above.

In this step, each of the six names that were added to the collection were displayed after they were arranged into their *natural ordering* .

In case you are unfamiliar with this aspect of character encoding, upper-case characters appear before lower-case characters in the *natural ordering* of characters in the Unicode character set. Therefore, the names consisting of all upper-case characters appear in the output ahead of the same names consisting of a mixture of upper-case and lower-case characters.

3.4.19.4.3.2 The second step

Then the program shown in Listing 1 (p. 1067) instantiates a new **TreeSet** object, providing a **Comparator** for use in comparing and managing the sort order of the elements.

The program populates the new **TreeSet** collection with the same set of six names in the same order as before. After the collection is populated, its contents are displayed producing the following output (*without the bullets*) :

- **Comparator in use**
- **Bill Joe Tom**

3.4.19.4.3.3 Duplicate names eliminated from the set

Three of the names appear in the output in the same order as the *natural ordering* shown earlier. However, the duplicate names were eliminated and only three names appear.

This is because a **Comparator** was used by the **TreeSet** object to compare the elements as they were added. The **Comparator** was designed to eliminate the distinction between upper-case and lower-case characters.

3.4.19.4.3.4 Does Joe equal JOE?

For the earlier case that didn't use a **Comparator** , the names **Joe** and **JOE** were considered to be different elements. Therefore, after population, both names appeared in the collection.

When the **Comparator** was used to eliminate the distinction between upper-case and lower-case characters, the names **Joe** and **JOE** were considered to be duplicates. As a result, only the first of the two was allowed into the collection and the second of the two was rejected.

3.4.19.4.4 Let's see some code

The code shown in Listing 2 (p. 1069) is the code that was used

- To instantiate a **TreeSet** object without a **Comparator** ,
- To populate the collection, and
- To display the contents of the collection after it was populated.

Listing 2 . Create, populate, and display a TreeSet collection.
<pre> ref = new TreeSet(); Populator.fillIt(ref); iter = ref.iterator(); while(iter.hasNext()){ System.out.print(iter.next() + " "); }//end while loop</pre>

Table 3.407

3.4.19.4.4.1 The Populator code

The code in Listing 3 (p. 1071) was used to populate the collection in both cases, both with, and without a **Comparator** (*to be discussed later*).

Listing 3 . The class named Populator.

```

class Populator{
public static void fillIt(Collection ref){
    ref.add("Joe");
    ref.add("Bill");
    ref.add("Tom");
    ref.add("JOE");
    ref.add("BILL");
    ref.add("TOM");
} //end fillIt()
} //end class Populator

```

Table 3.408**3.4.19.4.4.2 Populating the collection with String objects**

Note that in Listing 3 (p. 1071) , unlike earlier modules, I did not use a class of my own design from which to instantiate the objects used to populate the collection. Rather, I used the **String** class from the standard library.

The **String** class implements the **Comparable** interface. Therefore, objects instantiated from the **String** class have a *natural ordering* when placed in a collection.

Because the **compareTo** method of the **String** class, (*which implements the Comparable interface*) considers upper-case and lower-case characters to be different, there were no duplicate elements added to the collection when only the **compareTo** method was used to compare elements. The six **String** objects were simply arranged so that the iterator would return references to those objects in sorted order. This produced the output shown below:

BILL Bill JOE Joe TOM Tom

3.4.19.4.4.3 A TreeSet with a Comparator

The code shown in Listing 4 (p. 1071) was used to instantiate a new **TreeSet** object. A **Comparator** object's reference was passed to the **TreeSet** constructor. The **Comparator** object (*instead of the compareTo method*) was subsequently used for comparing and controlling the sorting order of the elements in the **TreeSet** collection.

Listing 4 . A TreeSet with a Comparator.

```

    ref = new TreeSet(new TheComparator());

    Populator.fillIt(ref);

    iter = ref.iterator();
    while(iter.hasNext()){
        System.out.print(iter.next() + " ");
    } //end while loop

```

Table 3.409

The code in Listing 4 (p. 1071) was also used to populate the collection, and to display the contents of the collection after it was populated.

3.4.19.4.4.4 Populating the TreeSet collection

As before, the `fillIt` method shown in Listing 5 (p. 1072) was used to populate the collection. The same six names as before were added to the `TreeSet` collection. However, the result of adding those six names was determined by the behavior of the `compare` method in the `Comparator` object used by the `TreeSet` object for managing the collection. (*Three of the names were rejected as duplicates.*)

Listing 5 . Populating the TreeSet collection.

```
public static void fillIt(Collection ref){
    ref.add("Joe");
    ref.add("Bill");
    ref.add("Tom");
    ref.add("JOE");
    ref.add("BILL");
    ref.add("TOM");
} //end fillIt()
```

Table 3.410

3.4.19.4.4.5 Beginning of the Comparator class

The code in Listing 6 (p. 1072) shows the beginning of the class from which the `Comparator` object was instantiated. Note that this class implements the `Comparator` interface, and therefore defines a concrete version of the method named `compare` .

Listing 6 . Beginning of the Comparator class.

```
class TheComparator
    implements Comparator,Serializable{

    public int compare(Object o1,Object o2){
        if(!(o1 instanceof String))
            throw new ClassCastException();
        if(!(o2 instanceof String))
            throw new ClassCastException();
```

Table 3.411

Listing 6 (p. 1072) doesn't contain the interesting part of this class. The code in Listing 6 (p. 1072) simply throws an exception if the `compare` method receives any incoming parameters of types other than `String` .

3.4.19.4.4.6 The interesting code

The interesting code in the method named `compare` is shown in Listing 7 (p. 1073) .

Listing 7 . The interesting code in the compare method.

```

    int result =
    ((String)o1).toUpperCase().
        compareTo(((String)o2).
            toUpperCase());
    return result;
} //end compare()

```

Table 3.412

The code in Listing 7 (p. 1073) makes use of two methods of the `String` class to compare the two incoming objects.

3.4.19.4.4.7 Convert to upper-case

The method named `toUpperCase` is used to produce a version of each of the incoming strings that consists of upper-case characters only. In other words, lower-case characters in each of the two strings are replaced by the corresponding upper-case characters. This conversion occurs before the strings are compared.

For example, the string `Joe` is temporarily converted to `JOE` inside the `compare` method, before the actual comparison is made. This results in the two strings containing `Joe` and `JOE` being considered to be duplicates. If one of them is already in the collection when an attempt is made to add the other, the second will be rejected as a duplicate.

3.4.19.4.4.8 Making the comparison

Then the `compareTo` method of the `String` class is used to make the actual comparison. (*Note that this is the same method that is used to make the comparison in the absence of a `Comparator` object. However, in the case of the `Comparator` object, the case of the strings is modified before they are passed to the `compareTo` method.*)

This code calls the `compareTo` method on the upper-case version of the string represented by `o1` , passing the upper-case version of the string represented by `o2` as a parameter. Here is part of what Oracle has to say about the behavior of the `compareTo` method.

"Returns: the value 0 if the argument is a string lexicographically equal to this string; a value less than 0 if the argument is a string lexicographically greater than this string; and a value greater than 0 if the argument is a string lexicographically less than this string."

3.4.19.4.4.9 Just what I was looking for

That is exactly the behavior that I was looking for, so all that I needed to do after calling the `compareTo` method on the upper-case versions of the two strings was to return the value that was returned by the `compareTo` method.

(*Note, while writing this module and explaining the behavior of this program, I discovered that I could have used a method of the `String` class named `compareToIgnoreCase` to accomplish the same thing with a little less work.*)

3.4.19.4.4.10 The results

When the **TreeSet** object used the **Comparator** object to compare and arrange the elements in the collection, the three *duplicate* names were eliminated and the iterator delivered references to the remaining three names in the following order:

Bill Joe Tom

3.4.19.5 Run the program

I encourage you to copy the code from Listing 1 (p. 1067) and paste it into your Java editor. Then compile and execute it.

Run the program and observe the results. Experiment with the code. Make changes, run the program again, and observe the results of your changes. Make certain that you can explain why your changes behave as they do.

3.4.19.6 Summary

In this module, I showed you how to use a **Comparator** object to achieve a *natural ordering* of a set of names (*String* objects) added to a **TreeSet** collection while ignoring the case used to write the names. (*Natural ordering for String objects is ascending.*)

3.4.19.7 What's next?

In the next module, I will show you how to use a **Comparator** to cause a **TreeSet** collection containing references to **String** objects to be sorted in descending order while preserving differences in case.

3.4.19.8 Miscellaneous

This section contains a variety of miscellaneous information.

3.4.20.5 Answers

3.4.20.5.1 Answer 5

A **Comparator** object's reference is passed to the **TreeSet** constructor when the second **TreeSet** object is instantiated. The **Comparator** is designed to eliminate the distinction between upper-case and lower-case characters when each new element is compared with the existing elements. This causes the last three names to be treated as duplicates of the first three names so they are not added to the collection. As a result, the collection ends up containing only the first three names that are added.

Back to Question 5 (p. 1076)

3.4.20.5.2 Answer 4

False. The second time the **fillIt** method is called in Listing 1 (p. 1079), the **TreeSet** collection referred to by the incoming parameter named **ref** is populated with the following names in the following order with duplicate elements eliminated:

Bill Joe Tom

Back to Question 4 (p. 1076)

3.4.20.5.3 Answer 3

False. The first time the **fillIt** method is called in Listing 1 (p. 1079), the **TreeSet** collection referred to by the incoming parameter named **ref** is populated with the following names in the following *natural order* for **String** objects. The **String** class implements the **Comparable** interface, and that is what determines the sorted order in this case.

3.4.21.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java Collections framework in particular.

The module shows you how to use a **Comparator** to cause a **TreeSet** collection to be sorted in *descending* order while preserving the impact of differences in case.

In addition to studying these modules, I strongly recommend that you study the Collections Trail ⁵¹⁹ in Oracle's Java Tutorials ⁵²⁰. The modules in this collection are intended to supplement and not to replace those tutorials.

3.4.21.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the listings while you are reading about them.

3.4.21.2.1.1 Listings

- Listing 1 (p. 1083) . The program named `Comparator04`.
- Listing 2 (p. 1084) . A new `TreeSet` object with a `Comparator`.
- Listing 3 (p. 1085) . The `fillIt` method.
- Listing 4 (p. 1085) . Beginning of the class named `TheComparator`.
- Listing 5 (p. 1086) . The most interesting code.

3.4.21.3 Preview

In this module, I will teach you how to use a **Comparator** to cause a **TreeSet** collection to be sorted in descending order while preserving the impact of differences in case. We might refer to this as *reverse natural order*. In other words, the sorting order is the same as the *natural order* except that the order is descending instead of ascending.

3.4.21.4 Generics

The code in this series of modules is written with no thought given to Generics ⁵²¹. As a result, if you copy and compile the code, you will probably get warnings about *unchecked or unsafe operations*.

⁵¹⁹<http://docs.oracle.com/javase/tutorial/collections/index.html>

⁵²⁰<http://docs.oracle.com/javase/tutorial/index.html>

⁵²¹<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.21.5 Discussion and sample code

3.4.21.5.1 Beginning with a quiz

Let's begin with a quiz to test your prior knowledge of the Collections Framework.

What output is produced by the program shown in Listing 1 (p. 1083) ?

- A. Compiler Error
- B. Runtime Error
- C. BILL Bill JOE Joe TOM Tom
- D. Tom TOM Joe JOE Bill BILL
- E. Joe Bill Tom
- F. None of the above.

Listing 1 . The program named Comparator04.

public class Comparator04{
    public static void main(String args[]){
        new Worker().doIt();
    }//end main()
}//end class Comparator04

class Worker{
    public void doIt(){
        Iterator iter;
        Collection ref;

        ref = new TreeSet(new TheComparator());
        Populator.fillIt(ref);
        iter = ref.iterator();
        while(iter.hasNext()){
            System.out.print(iter.next() + " ");
        }//end while loop
        System.out.println();

    }//end doIt()
}// end class Worker

class Populator{
    public static void fillIt(Collection ref){
        ref.add("Joe");
        ref.add("Bill");
        ref.add("Tom");
        ref.add("JOE");
        ref.add("BILL");
        ref.add("TOM");
    }//end fillIt()
}//end class Populator

class TheComparator implements Comparator,Serializable{

        if(!(o1 instanceof String))
            throw new ClassCastException();
        if(!(o2 instanceof String))
            throw new ClassCastException();

        int result = ((String)o1).compareTo(((String)o2));
        return result*(-1);
    }//end compare()

    public boolean equals(Object o){
        if(!(o instanceof TheComparator))
            return false;

```

Table 3.414

If you selected the following, you are correct:

D. Tom TOM Joe JOE Bill BILL

3.4.21.5.1.1 Similar to previous programs

The overall structure of this program is very similar to programs that I have discussed in previous modules. Therefore, I will concentrate on those aspects of this program that differentiate it from the programs in previous modules.

3.4.21.5.1.2 A new TreeSet object with a Comparator

The code in Listing 2 (p. 1084) instantiates a new `TreeSet` object, by providing a reference to an anonymous object that implements the `Comparator` interface. That object is instantiated from the class named `TheComparator`. It is the `Comparator` object that will be of most interest to us in this module.

Listing 2 . A new TreeSet object with a Comparator.

```

    Collection ref;

    ref = new TreeSet(new TheComparator());
    Populator.fillIt(ref);

    iter = ref.iterator();
    while(iter.hasNext()){
        System.out.print(iter.next() + " ");
    }//end while loop

```

Table 3.415

3.4.21.5.1.3 Populating the TreeSet collection

After the `TreeSet` object is instantiated, it is passed to a method named `fillIt` where the `TreeSet` collection is populated with the names of several people.

3.4.21.5.1.4 Display the contents of the TreeSet collection

As shown by the code in Listing 2 (p. 1084), after the `TreeSet` collection is populated, an `Iterator` is obtained for that collection and used to display the contents of the collection. The output produced by the program is **shown below** :

Tom TOM Joe JOE Bill BILL

3.4.21.5.2 Analyzing the contents of the TreeSet collection

We will need to compare this output with the names used to populate the collection to appreciate the true significance of the use of the `Comparator` object.

At this point, it is worth pointing out that the six names contained in the collection are returned by the iterator in *descending order*, taking the significance of upper and lower case into account. In other words,

names beginning with letters that are high in the alphabet occur before names beginning with letters that are lower in the alphabet. In addition, names containing lower case characters appear before the same names containing only upper case characters.

3.4.21.5.2.1 Method used to populate the collection

Listing 3 (p. 1085) shows the method named `fillIt` that was used to populate the collection with references to six `String` objects. As you can see, the names weren't added in any particular order.

As you can also see by comparing Listing 3 (p. 1085) with the output shown above (p. 1084), all six names that were added to the collection were displayed in the output, but in a different order from the order in which they were added. (*Names with the same spelling but different case were not considered to be duplicates insofar as the contract for the set was concerned.*)

Listing 3 . The `fillIt` method.

```
public static void fillIt(Collection ref){
ref.add("Joe");
ref.add("Bill");
ref.add("Tom");
ref.add("JOE");
ref.add("BILL");
ref.add("TOM");
} //end fillIt()
```

Table 3.416

3.4.21.5.2.2 Implementing the `Comparator` interface

That brings us to the class from which the `Comparator` object was instantiated. The beginning portion of that class is shown in Listing 4 (p. 1085).

Listing 4 . Beginning of the class named `TheComparator`.

```
class TheComparator implements Comparator,Serializable{

public int compare(Object o1,Object o2){
if(!(o1 instanceof String))
throw new ClassCastException();
if(!(o2 instanceof String))
throw new ClassCastException();
```

Table 3.417

The code in Listing 4 (p. 1085) isn't particularly interesting. That code simply throws an exception if either of the references passed to the `compare` method refer to an object of some type other than `String`.

3.4.21.5.2.3 The interesting code

The most interesting code is shown in Listing 5 (p. 1086) . The first statement in Listing 5 (p. 1086) uses the `compareTo` method of the `String` class to compare the two objects in an *ascending natural ordering* sense. The behavior of this method is more formally described as follows:

"Returns: the value 0 if the argument is a string lexicographically equal to this string; a value less than 0 if the argument is a string lexicographically greater than this string; and a value greater than 0 if the argument is a string lexicographically less than this string."

Listing 5 . The most interesting code.

```
int result = ((String)o1).compareTo(((String)o2));
return result*(-1);
```

Table 3.418

3.4.21.5.2.4 Converting to reverse natural order

The most interesting line of code in this entire program is the `return` statement shown in Listing 5 (p. 1086) . This line of code changes the sign on the value returned by the `compareTo` method before returning it as the return value for the `compare` method.

The effect of changing the sign is to return a value that causes the `TreeSet` collection to arrange the elements in *reverse natural order* instead of the normal *ascending natural order*.

As a result, the use of an iterator to access and display the contents of the collection produces the following output:

Tom TOM Joe JOE Bill BILL

For comparison, if the names were arranged in *ascending natural order*, the output would be as shown below:

BILL Bill JOE Joe TOM Tom

3.4.21.6 Run the program

I encourage you to copy the code from Listing 1 (p. 1083) and paste it into your Java text editor. Then compile and execute it.

Run the program and observe the results. Experiment with the code. Make changes, run the program again, and observe the results of your changes. Make certain that you can explain why your changes behave as they do.

3.4.21.7 Summary

In this module, I taught you how to use a `Comparator` to cause a `TreeSet` collection to be sorted in *reverse natural order*. In other words, the sorting order is the same as the *natural order* except that the order is descending instead of ascending.

3.4.21.8 What's next?

In the next module, I will show you how to use a `Comparator` object to sort the contents of an array.

This module contains review questions and answers keyed to the module titled Java4110: The Comparator Interface, Part 3 ⁵²⁵.

Once you study that module, you should be able to answer the review questions in this module.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

3.4.22.3 Questions

3.4.22.3.1 Question 1 .

What output is produced by the program shown in Listing 1 (p. 1092) ?

- Compiler Error
- Runtime Error
- BILL Bill JOE Joe TOM Tom
- Tom TOM Joe JOE Bill BILL
- Joe Bill Tom
- None of the above.

Answer 1 (p. 1091)

3.4.22.3.2 Question 2

True or False? The `fillIt` method in Listing 1 (p. 1092) populates the `TreeSet` object referred by the incoming parameter with the following names in the following order:

Joe Bill Tom JOE BILL TOM

3.4.22.3.3 Question 3

True or False? When the `fillIt` method in Listing 1 (p. 1092) returns, the `TreeSet` object is populated with six names in descending order taking case into account.

Answer 3 (p. 1091)

3.4.22.3.4 Question 4

True or False? In the output from Listing 1 (p. 1092), descending order means that names beginning with letters that are low in the alphabet occur before names beginning with letters that are higher in the alphabet. In addition, names containing lower case characters appear before the same names containing only upper case characters.

Answer 4 (p. 1091)

3.4.22.3.5 Question 5

True or False? In Listing 1 (p. 1092), names with the same spelling but different case were considered to be duplicates and therefore were excluded from the collection

Answer 5 (p. 1091)

3.4.22.3.6 Question 6

True or False? Given: Listing 1 (p. 1092) contains the following statement:

```
return result*(-1);
```

If you were to change the value in parentheses from -1 to -2, the program output would be:

```
BILL Bill JOE Joe TOM Tom
```

Answer 6 (p. 1091)

3.4.22.4 Listings

- Listing 1 (p. 1092) . Comparator04.java.

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

3.4.22.5 Answers**3.4.22.5.1 Answer 6**

False. If you were to change the value in parentheses from -1 to -2, the program output would still be:

Tom TOM Joe JOE Bill BILL

It is the sign of the result and not the value of the result that determines the sorting order of the output in Listing 1 (p. 1092) . You would need to multiply by a positive value to cause the output to be

BILL Bill JOE Joe TOM Tom

Back to Question 6 (p. 1089)

3.4.22.5.2 Answer 5

False. In Listing 1 (p. 1092) , names with the same spelling but different case were not considered to be duplicates insofar as the contract for the set was concerned.

Back to Question 5 (p. 1089)

3.4.22.5.3 Answer 4

False. In the output from Listing 1 (p. 1092) , descending order means that names beginning with letters that are high in the alphabet occur before names beginning with letters that are lower in the alphabet. In addition, names containing lower case characters appear before the same names containing only upper case characters.

Back to Question 4 (p. 1089)

3.4.22.5.4 Answer 3

True.

Back to Question 3 (p. 1089)

3.4.22.5.5 Answer 2

False. Even without the use of a **Comparator** object, the order would be incorrect. A **TreeSet** object requires its elements to be in either ascending natural order or in an order specified by a **Comparator** object. This program uses a **Comparator** object but it doesn't result in the order shown in the question.

Back to Question 2 (p. 1088)

3.4.22.5.6 Answer 1

Tom TOM Joe JOE Bill BILL

3.4.23.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java Collections framework in particular.

This module shows you how to extract the contents of a collection into an array, and how to use a **Comparator** object to sort the contents of the array into reverse natural order. The module also shows you how to sort the contents of the array into natural order without the use of a **Comparator** object.

In addition to studying these modules, I strongly recommend that you study the Collections Trail ⁵²⁹ in Oracle's Java Tutorials ⁵³⁰. The modules in this collection are intended to supplement and not to replace those tutorials.

3.4.23.3 Preview

The primary purpose of recent modules in this series was to teach you about the interactions between the **Comparator** interface and the Collections Framework.

This module departs somewhat from that primary purpose and teaches you how to use a **Comparator** object to sort the contents of an array containing references to objects. Technically speaking, an array is not part of the core Collections Framework. However, it is definitely a first cousin to the Framework.

3.4.23.3.1 An array is a container

As you should already know, an array is a container that can be used to store a collection of primitive values or a collection of references to objects.

The **Collection** interface declares a method named `toArray` , which can be called on a **Collection** object to *"return an array containing all of the elements in this collection whose runtime type is that of the specified array"* .

3.4.23.3.2 An opportune time

Since you are studying this sub-series of modules to learn about the uses of the **Comparator** interface, this seems like an opportune time to teach you how to get an array from a collection, and how to use the **Comparator** interface to sort the contents of the array. (*While I'm at it, I will also teach you how to sort the elements in an array of object references into natural order without the use of a `Comparator` object.*)

3.4.23.4 Generics

The code in this series of modules is written with no thought given to Generics⁵³¹ . As a result, if you copy and compile the code, you will probably get warnings about *unchecked or unsafe operations* .

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.23.5 Discussion and sample code

3.4.23.5.1 Beginning with a quiz

See if you can write down the output produced by the program shown in Listing 1 (p. 1096) .

⁵³¹<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

Listing 1 . The program named Comparator 05 .

        new Worker().doIt();
    }//end main()
}//end class Comparator05

class Worker{
    public void doIt(){
        Iterator iter;
        Collection ref;
        Object[] array;

        ref = new Vector();
        Populator.fillIt(ref);
        iter = ref.iterator();
        System.out.println("Collection data");
        while(iter.hasNext()){
            System.out.print(iter.next() + " ");
        }//end while loop
        System.out.println();

        array = ref.toArray();
        System.out.println("Raw array data");
        display(array);

        //Sort the array into natural order
        // and display it.
        Arrays.sort(array);

    }//end doIt()

    static void display(Object[] array){

Table 3.420

If you wrote down the following for the program output, you already understand most of the material covered in this module and you can probably skip this module and move on to the next module.

```

Collection data
Joe Bill Tom JOE BILL TOM
Raw array data
Joe Bill Tom JOE BILL TOM
Natural order sorted array data
BILL Bill JOE Joe TOM Tom
Custom order sorted array data
Tom TOM Joe JOE Bill BILL
Collection data
Joe Bill Tom JOE BILL TOM

```

If you didn't write down the correct output for the program in Listing 1 (p. 1096) , you should probably continue with your study of this module.

3.4.23.5.1.1 Similar to previous programs

Although this program is somewhat more complex, the overall structure of this program is similar to programs that I have discussed in previous modules. Therefore, I will concentrate on those aspects of this program that differentiate it from the programs in previous modules.

3.4.23.5.1.2 A new Vector object

The code in Listing 2 (p. 1097) instantiates a new object of the **Vector** class and stores a reference to that object in the variable named **ref** .

Listing 2 . A new Vector object.

```
ref = new Vector();
```

Table 3.421

The **Vector** class was part of Java long before the Collections Framework was released. However, with the release of the Collections Framework, the **Vector** class was upgraded to implement the **Collection** interface and the **List** interface.

3.4.23.5.1.3 A Vector is a List

Therefore, a **Vector** is a **List** , and adheres to the various contracts of the **List** interface. For example, since it is not a **Set** , it doesn't prohibit duplicate elements. Because it is a **List** , it is an *ordered* collection. The position of each element in the collection is determined by a numeric index associated with the element and is independent of the value of the element.

3.4.23.5.1.4 The fillIt method

As has been the case in several of the programs in previous modules, the code in Listing 3 (p. 1098) passes the **Vector** object's reference to a method named **fillIt** where the **Vector** is populated with the names of several people.

Listing 3 . Call the fillIt method.
--

<pre>Populator.fillIt(ref);</pre>

Table 3.422

The code for the **fillIt** method is shown in Listing 4 (p. 1098) . As you can see, the names were added to the collection in no particular order relative to their values. *(The add method for the Vector class simply adds each new element to the end of the list.)*

Listing 4 . The fillIt method.

<pre>class Populator{ public static void fillIt(Collection ref){ ref.add("Joe"); ref.add("Bill"); ref.add("Tom"); ref.add("JOE"); ref.add("BILL"); ref.add("TOM"); } //end fillIt() } //end class Populator</pre>
--

Table 3.423

3.4.23.5.1.5 Iteration on a Vector

When an iterator is used to traverse the elements in a **Vector** collection, the elements are delivered by the iterator in ascending index order, beginning with the element stored at index 0.

The code in Listing 5 (p. 1099) gets and uses an iterator to display the contents of the populated collection.

Listing 5 . Iteration on a Vector.

<i>continued on next page</i>

```

        iter = ref.iterator();
    System.out.println("Collection data");
    while(iter.hasNext()){
        System.out.print(iter.next() + " ");
    }//end while loop

```

Table 3.424

3.4.23.5.1.6 The output

The code in Listing 5 (p. 1099) produces the following output:

```

    Collection data
    Joe Bill Tom JOE BILL TOM

```

As you can see, this is the same order in which the names were added to the collection by the `fillIt` method in Listing 4 (p. 1098) .

3.4.23.5.2 The toArray method

The code in Listing 6 (p. 1099) is new to this module. This code calls the `toArray` method on the `Vector` object to extract the contents of the collection and store the elements in an array object of type `Object` .

Listing 6 . Call the toArray method.

```

    array = ref.toArray();

```

Table 3.425

(Recall that the variable named `array` was declared as a reference to an array object of type `Object` in Listing 1 (p. 1096) (p. 1096) .)

3.4.23.5.2.1 The contract

According to the documentation for the `Vector` class, this version of the `toArray` method:

"Returns an array containing all of the elements in this Vector in the correct order."

The documentation for the `toArray` method of the `Collection` interface is a little more verbose, reading partially as follows:

"Returns an array containing all of the elements in this collection. If the collection makes any guarantees as to what order its elements are returned by its iterator, this method must return the elements in the same order."

3.4.23.5.2.2 Elements are returned in ascending index order

By default, the iterator for a **Vector** returns its elements in ascending index order. Therefore, the **toArray** method for a **Vector** object must return the elements in the same order.

3.4.23.5.2.3 A "safe" array

Also, according to Oracle:

*"The returned array will be "safe" in that no references to it are maintained by this collection.
... The caller is thus free to modify the returned array."*

In the code in Listing 6 (p. 1099) above, the returned reference to an array object is assigned to a reference variable that previously contained null. Following the execution of the **toArray** method, that reference variable refers to an array object of type **Object** containing the same elements as the **Vector** collection, in ascending index order.

(Regarding the concept of a "safe" array, it is easy to demonstrate that the elements in the array refer to the same objects referred to by the elements in the Vector. Thus, using the references stored in the array to modify the objects to which they refer also modifies the objects referred to by the elements stored in the Vector. In other words, the elements in the array are copies of the elements in the Vector. The elements in the array refer to the original objects, and do not refer to copies (or clones) of those objects. As usual when dealing with multiple references to objects, care should be taken to avoid inadvertently corrupting those objects.)

3.4.23.5.2.4 Display the contents of the array

The code in Listing 7 (p. 1100) passes the array object's reference to a method named **display** that displays the contents of the array in ascending index order.

Listing 7 . Display the contents of the array.
<pre>System.out.println("Raw array data"); display(array);</pre>

Table 3.426

The output produced by the code in Listing 7 (p. 1100) is as shown below:

```
Raw array data
Joe Bill Tom JOE BILL TOM
```

As you can see, this is the same data, in the same order, as the contents of the collection displayed earlier.

*(The method named **display** is a simple utility method that I won't discuss here because of its simplicity. You can view the display method in its entirety in Listing 1 (p. 1096) .)*

3.4.23.5.3 Sorting the array into *natural order*

The code in Listing 8 (p. 1101) is also new to this module. This code uses one of the overloaded **sort** methods of the **Arrays** class to sort the contents of the array into *natural order* .

Listing 8 . Sorting the array into natural order.

```
Arrays.sort(array);
```

Table 3.427

Here is part of what Oracle has to say about the **Arrays** class:

"This class contains various methods for manipulating arrays (such as sorting and searching)."

The class contains many overloaded versions of the **sort** method. Here is part of what Oracle has to say about the version of the **sort** method used in Listing 8 (p. 1101) above:

"Sorts the specified array of objects into ascending order, according to the natural ordering of its elements. All elements in the array must implement the Comparable interface."

3.4.23.5.3.1 The Comparable interface and polymorphic behavior

Although the declared type of the array is **Object**, the array actually contains references to **String** objects.

The **String** class implements the **Comparable** interface. It is not necessary to cast the array to type **String** before passing it to the **Sort** method. (*The **Sort** method declares the incoming parameter as type **Object**.*)

The **sort** method treats the array elements as type **Comparable** and uses the **compareTo** method declared in that interface to perform any necessary comparisons required to carry out the sorting operation.

This is another example of the usefulness of polymorphism as implemented through the use of the Java interface. (*The **Comparable** interface and the **compareTo** method declared in that interface were discussed in detail in an earlier module.*)

3.4.23.5.3.2 Display the sorted array data

The code in Listing 9 (p. 1101) displays the contents of the array after those contents are sorted into *natural order* by the **sort** method in Listing 8 (p. 1101) above.

Listing 9 . Display the sorted array data.

```
System.out.println("Natural order sorted " +
                  "array data");
display(array);
```

Table 3.428

The output produced by Listing 9 (p. 1101) above is:

```
Natural order sorted array data
BILL Bill JOE Joe TOM Tom
```

3.4.23.5.3.3 The *natural order* for String objects

I discussed the concept of *natural ordering* in a previous module with particular emphasis of the *natural order* for strings. You will recognize that the strings shown in the above output have been sorted into *natural order* according to the definition of the `compareTo` method of the `String` class.

3.4.23.5.4 Sort the array with a Comparator

The code in Listing 10 (p. 1102) is also new to this module. This code uses a different version of the overloaded `sort` method of the `Arrays` class to sort the array using the rules defined in the `compare` method of a `Comparator` object (*passed as a parameter to the sort method*).

Listing 10 . Sort the array with a Comparator.

```
Arrays.sort(array, new TheComparator());
```

Table 3.429

3.4.23.5.4.1 What does Oracle have to say about this?

Here is part of what Oracle has to say about this version of the `sort` method of the `Arrays` class:

"Sorts the specified array of objects according to the order induced by the specified comparator. All elements in the array must be mutually comparable by the specified comparator (that is, `c.compare(e1, e2)` must not throw a `ClassCastException` for any elements `e1` and `e2` in the array)."

3.4.23.5.4.2 The class named `TheComparator`

Listing 11 (p. 1102) shows the class from which the `Comparator` object was instantiated.

This is essentially the same class that was used to instantiate a `Comparator` object in an earlier module. I discussed the `compare` method in detail in that module and won't repeat that discussion here.

Listing 11 . The class named `TheComparator`.

```
class TheComparator implements Comparator,Serializable{
public int compare(Object o1,Object o2){
    if(!(o1 instanceof String))
        throw new ClassCastException();
    if(!(o2 instanceof String))
        throw new ClassCastException();

    int result = ((String)o1).compareTo(((String)o2));
    return result*(-1);
} //end compare()
} //end class TheComparator
```

Table 3.430

Suffice it to say at this point that this **Comparator** object causes the elements in the array to be sorted into *reverse natural order*. That term was also explained in the previous module, so I won't discuss it further here.

3.4.23.5.4.3 Display the array contents again

The code in Listing 12 (p. 1103) was used to display the newly-sorted contents of the array.

Listing 12 . Display the contents again.

```
System.out.println("Custom order sorted " +
                  "array data");
display(array);
```

Table 3.431

The output produced by this code is:

```
Custom order sorted array data
Tom TOM Joe JOE Bill BILL
```

You will recognize this as *reverse natural order* for the elements contained in the array.

3.4.23.5.4.4 Could have sorted differently

It is important to note that I could have caused the sorting order to be different from *reverse natural order* simply by defining the rules used for comparison in the **compare** method shown in Listing 11 (p. 1102) above. This makes it possible for you to sort array data into any order that you choose as long as you can write the sorting rules into the **compare** method of a class that implements the **Comparator** interface.

3.4.23.5.5 Display the collection data again

Finally, in order to show that none of this has disturbed the contents of the original collection, the code in Listing 13 (p. 1103) gets and uses an iterator to display the contents of the **Vector** collection.

Listing 13 . Display the collection data again.

```
iter = ref.iterator();
System.out.println("Collection data");
while(iter.hasNext()){
    System.out.print(iter.next() + " ");
} //end while loop
```

Table 3.432

The output produced by the code in Listing 13 (p. 1103) is:

```
Collection data
Joe Bill Tom JOE BILL TOM
```

If you compare this with the output produced by the code at the beginning of the program, you will see that the iterator still returns the elements in the **Vector** in the same order that they were added. Thus, modifications to the array did not disturb the contents of the **Vector** collection.

3.4.23.5.6 The bottom line

The **toArray** method of the **Collection** interface makes it possible to extract a copy of the elements in a collection into an array and to manipulate those elements in whatever way you wish. As mentioned earlier, however, care should be exercised to make certain that the copies of the references to the original objects are not used to corrupt the objects.

The various versions of the **sort** method in the **Arrays** class make it possible to sort the contents of arrays in a variety of different ways.

3.4.23.6 Run the program

I encourage you to copy the code from Listing 1 (p. 1096) . Paste the code into your Java editor. Then compile and execute it.

Run the program and observe the results. Experiment with the code. Make changes, run the program again, and observe the results of your changes. Make certain that you can explain why your changes behave as they do.

3.4.23.7 Summary

In this module, I taught you how to extract the contents of a collection into an array and how to use a **Comparator** to sort the contents of the array into *reverse natural order* .

Although I elected to use *reverse natural order* for purposes of illustration, I could have sorted the array into some other order simply by defining the comparison rules in the **compare** method of the **Comparator** class differently.

In order to further expand your knowledge of array sorting, I also sorted the array into *natural order* without the use of a **Comparator** .

Sorting the contents of the array did not disturb the contents of the **Vector** collection from which the contents of the array were derived.

3.4.23.8 What's next?

In the next module, I will show you how to use the **sort** method of the **Collections** class along with a **Comparator** object to sort the contents of a **List** .

3.4.24.3.3 Question 3

True or False? An array is a container that can be used to store a collection of primitive values or a collection of references to objects.

Answer 3 (p. 1111)

3.4.24.3.4 Question 4

Write down the output produced by the program shown in Listing 1 (p. 1112) . Hint: There are ten lines of output.

Answer 4 (p. 1111)

3.4.24.3.5 Question 5

True or False? A **Vector** object is a **Set** object.

Answer 5 (p. 1111)

3.4.24.3.6 Question 6

True or False? Because a **Vector** object is a **List** object, it is not allowed to contain duplicate elements.

Answer 6 (p. 1111)

3.4.24.3.7 Question 7

True or False? Because a **Vector** is a **List** , it is an *ordered* collection.

Answer 7 (p. 1111)

3.4.24.3.8 Question 8

True or False? The position of each element in an *ordered* collection is determined by *i* (p. 1110) ts value relative to the values of its neighbors.

Answer 8 (p. 1110)

3.4.24.3.9 Question 9

True or False? The **add** method for the **Vector** class simply adds each new element to the end of the list.

Answer 9 (p. 1110)

3.4.24.3.10 Question 10

True or False? When an iterator is used to traverse the elements in a **Vector** collection, the elements are delivered by the iterator in ascending index order, beginning with the element stored at index 0.

Answer 10 (p. 1110)

3.4.24.3.11 Question 11

True or False? The first time the iterator is applied to the **Vector** object in Listing 1 (p. 1112) , the output is in ascending natural order as shown below:

BILL Bill JOE Joe TOM Tom

Answer 11 (p. 1110)

3.4.24.3.12 Question 12

True or False? The `toArray` method can be called on a `Vector` object to return a reference to an array object containing all of the elements in the `Vector` in ascending index order.

Answer 12 (p. 1110)

3.4.24.3.13 Question 13

True or False? The documentation for the `toArray` method of the `Collection` interface reads partially as follows:

"Returns an array containing all of the elements in this collection. If the collection makes any guarantees as to what order its elements are returned by its iterator, this method must return the elements in the same order."

Answer 13 (p. 1110)

3.4.24.3.14 Question 14

True or False? There is a class named `Arrays` that contains various methods for manipulating arrays (such as sorting and searching). The `Arrays` class contains many overloaded versions of the `sort` method. As usual, each overloaded version of the `sort` method requires a different argument list.

Answer 14 (p. 1110)

3.4.24.3.15 Question 15

Given: Listing 1 (p. 1112) makes two calls to overloaded `sort` methods of the `Arrays` class using the following overloaded methods. (Note that I omitted generics syntax from the signatures because generics is beyond the scope of this course.)

- `sort(Object[] a)`
- `sort(Object[] a, Comparator c)`

True or False? In Listing 1 (p. 1112), the call to the first sort method in the above list (p. 1108) produces the following output:

Tom TOM Joe JOE Bill BILL

Answer 15 (p. 1110)

3.4.24.3.16 Question 16

True or False? In Listing 1 (p. 1112), the call to the second sort method in the above list (p. 1108) produces the following output:

Tom TOM Joe JOE Bill BILL

3.4.24.5.2 Answer 15

False. Here is what the documentation has to say about this overloaded version of the **Arrays.sort** method:
Sorts the specified array of objects into ascending order, according to the natural ordering of its elements. All elements in the array must implement the Comparable interface.

According to that specification, the output would be:

3.4.25.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java Collections framework in particular.

This module shows you how to use the `sort` method of the `Collections` class along with a `Comparator` object to sort the contents of a `List` into reverse natural order.

In addition to studying these modules, I strongly recommend that you study the Collections Trail ⁵³⁹ in Oracle's Java Tutorials ⁵⁴⁰. The modules in this collection are intended to supplement and not to replace those tutorials.

3.4.25.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the listings while you are reading about them.

3.4.25.2.1.1 Listings

- Listing 1 (p. 1116) . The program named `Comparator06`.
- Listing 2 (p. 1117) . A new `LinkedList` object.
- Listing 3 (p. 1118) . The `fillIt` method.
- Listing 4 (p. 1118) . Sort the list.
- Listing 5 (p. 1120) . The `Comparator`.
- Listing 6 (p. 1120) . Display the sorted list.

3.4.25.3 Preview

In this module, I will teach you how to use the `sort` method of the `Collections` class along with a `Comparator` object to sort the contents of a `List` into *reverse natural order*.

The methodology that I will teach you is completely general, and can be used to sort a list in a wide variety of ways, depending on how you define the `compare` method of a `Comparator` object.

Furthermore, the same `sort` method and the same `Comparator` object can be used to sort any implementation of a list, so long as the list properly implements the `List` interface.

3.4.25.4 Generics

The code in this series of modules is written with no thought given to Generics ⁵⁴¹ . As a result, if you copy and compile the code, you will probably get warnings about *unchecked or unsafe operations* .

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.25.5 Discussion and sample code

3.4.25.5.1 Beginning with a quiz

Let's begin with a quiz to test your prior knowledge of the Collections Framework.

What output is produced by the program shown in Listing 1 (p. 1116) ?

- A. Compiler Error
- B. Runtime Error
- C. BILL Bill JOE Joe TOM Tom
- D. Tom TOM Joe JOE Bill BILL
- E. Joe Bill Tom
- F. None of the above.

        Collection ref;

        ref = new LinkedList();
        Populator.fillIt(ref);
        Collections.sort((List)ref, new TheComparator());
        iter = ref.iterator();
        while(iter.hasNext()){
            System.out.print(iter.next() + " ");
        }//end while loop
        System.out.println();

    }//end doIt()

            throw new ClassCastException();

        //Do a comparison

The output produced by this program is shown below:

Tom TOM Joe JOE Bill BILL

If that was your answer, you probably already understand most of the material covered in this module. In that case, you might consider skipping this module and moving on to the next module. If that wasn't your answer, you should probably continue with your study of this module.

3.4.25.5.1.1 Similar to previous programs

The overall structure of the program in Listing 1 (p. 1116) is similar to programs that I have discussed in previous modules. Therefore, I will concentrate on those aspects of this program that differentiate it from the programs in previous modules.

3.4.25.5.1.2 A new `LinkedList` object

The code in Listing 2 (p. 1117) instantiates a new `LinkedList` object and passes that object's reference to a method named `fillIt` where it is populated with the names of several people.

Listing 2 . A new `LinkedList` object.

```
ref = new LinkedList();
Populator.fillIt(ref);
```

Table 3.435

The `LinkedList` class is one of the concrete implementation classes of the Collections Framework. This class implements the `Collection` interface and the `List` interface. Here is part of what Oracle has to say about the `LinkedList` class:

"Linked list implementation of the List interface. Implements all optional list operations, and permits all elements (including null). In addition to implementing the List interface, the LinkedList class provides uniformly named methods to get, remove and insert an element at the beginning and end of the list. These operations allow linked lists to be used as a stack, queue, or double-ended queue (deque)."

3.4.25.5.1.3 Populating the List

The code in Listing 3 (p. 1118) shows the `fillIt` method that is used to populate the list with references to six different `String` objects.

The `add` method is used to add each new element to the end of the list. As you can see, the elements are added to the list in no particular order with respect to their values.

Listing 3 . The fillIt method.

```

class Populator{
public static void fillIt(Collection ref){
    ref.add("Joe");
    ref.add("Bill");
    ref.add("Tom");
    ref.add("JOE");
    ref.add("BILL");
    ref.add("TOM");
} //end fillIt()
} //end class Populator

```

Table 3.436**3.4.25.5.1.4 Displaying the list**

Although I didn't bother to do so in this program, if an iterator were to be used to access and display the elements in the list following the invocation of the **fillIt** method, the result would be as shown below:

Joe Bill Tom JOE BILL TOM

As you can see, this is the same as the order in which the elements are added to the list. The first element is added to the list at index value 0 and the sixth element is added to the list at index value 5.

3.4.25.5.1.5 Sort the list

The code shown in Listing 4 (p. 1118) is new to this module. This code uses the **sort** method of the **Collections** class, along with a **Comparator** object to sort the contents of the list.

Listing 4 . Sort the list.

```

Collections.sort((List)ref, new TheComparator());

```

Table 3.437

*The sort method expects to receive an incoming parameter of type **List** . Therefore, it was necessary to cast the reference from type **Collection** to type **List** .*

3.4.25.5.1.6 A very important point

Unlike the programs in previous modules that simply extracted the contents of the collection into an array and sorted the array, this code actually rearranges the contents of the list according to the sorting rules.

(The programs in previous modules that sorted the array did not rearrange the contents of the list. Only the contents of the array were rearranged.)

Thus, the relationship between an element in the list and the index associated with that element can change as a result of the sorting operation shown in Listing 4 (p. 1118) .

Following the sort, when an iterator is used to access the elements, the elements will be returned by the iterator in the newly-sorted order.

3.4.25.5.2 The Collections class

Despite the similarity of the names, the **Collections** class is different from the **Collection** interface. Here is part of what Oracle has to say about the **Collections** class:

"This class consists exclusively of static methods that operate on or return collections. It contains polymorphic algorithms that operate on collections, "wrappers", which return a new collection backed by a specified collection, and a few other odds and ends."

3.4.25.5.2.1 The sort method

The **Collections** class provides a large number of very interesting and useful methods, such as **binarySearch**, **copy**, **reverse**, and **reverseOrder**. (The **reverseOrder** method will be examined in the next module.)

One of the static methods of the **Collections** class is the **sort** method. One overloaded version of the **sort** method can be used to sort a list into the *natural ordering* of its elements. Another overloaded version sorts a list according to the order induced by a **Comparator**.

Here is part of what Oracle has to say about this second version of the **sort** method that uses a **Comparator**:

public static void sort(List list, Comparator c) *"Sorts the specified list according to the order induced by the specified comparator. All elements in the list must be mutually comparable using the specified comparator ..."*

"The specified list must be modifiable, but need not be resizable. This implementation dumps the specified list into an array, sorts the array, and iterates over the list resetting each element from the corresponding position in the array. This avoids the $n^2 \log(n)$ performance that would result from attempting to sort a linked list in place."

3.4.25.5.2.2 Also uses an array

I find it interesting that the **sort** method uses an array as an intermediary in the sorting process. However, the difference between this approach and the approach involving arrays shown in previous modules is given by the following excerpt from the above quotation:

"iterates over the list resetting each element from the corresponding position in the array"

In other words, after sorting the array, the **sort** method uses the sorted results in the array to rearrange the positions of the elements in the list, resulting in a sorted list.

3.4.25.5.2.3 A flexible approach to sorting

Thus, the **sort** method of the **Collections** class can be used to sort the elements in a list using whatever set of comparison rules you program into the **compare** method of the **Comparator** object. Furthermore, it doesn't matter how the list is actually implemented so long as it properly implements the **List** interface.

3.4.25.5.3 The Comparator

The code in Listing 5 (p. 1120) shows the class from which the **Comparator** object was instantiated.

Listing 5 . The Comparator.

```

class TheComparator implements Comparator,Serializable{

public int compare(Object o1,Object o2){
    if(!(o1 instanceof String))
        throw new ClassCastException();
    if(!(o2 instanceof String))
        throw new ClassCastException();

    int result = ((String)o1).compareTo(((String)o2));
    return result*(-1);
} //end compare()
} //end class TheComparator

```

Table 3.438

I have presented and explained this class in previous modules, so I won't discuss it in detail again here. Suffice it for now to say that an object instantiated from this class will induce the list to be sorted into *reverse natural order* .

3.4.25.5.4 Display the sorted list

The code in Listing 6 (p. 1120) gets and uses an iterator to display the contents of the sorted list.

Listing 6 . Display the sorted list.

```

    iter = ref.iterator();
    while(iter.hasNext()){
        System.out.print(iter.next() + " ");
    } //end while loop

```

Table 3.439

The output produced by the code in Listing 6 (p. 1120) is shown below:

Tom TOM Joe JOE Bill BILL

As you can see, this is *reverse natural order* as induced by the **Comparator** object.

3.4.25.6 Run the program

I encourage you to copy the code from Listing 1 (p. 1116) . Paste the code into your Java editor. Then compile and execute it.

Run the program and observe the results. Experiment with the code. Make changes, run the program again, and observe the results of your changes. Make certain that you can explain why your changes behave as they do.

3.4.25.7 Summary

In this module, I taught you how to use the sort method of the **Collections** class along with a **Comparator** object to sort the contents of a list.

By using this approach, you can sort the contents of list according to any set of comparison rules that you can program into the **compare** method of the **Comparator** object.

Furthermore, the ability to sort the list is independent of the actual implementation of the list, so long as the list properly implements the **List** interface. For example, the same **Comparator** object (*and the same code*) can be used to sort an **ArrayList**, a **LinkedList**, or a **Vector**, producing the same results regardless of which class the list object is instantiated from.

3.4.25.8 What's next?

In the next module, I will show you how to use a **Comparator** created by the **reverseOrder** method of the **Collections** class to sort a list into *reverse natural order*. I will also show you how to use the **reverse** method of the **Collections** class to reverse the order of the elements in a list.

3.4.27.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java Collections framework in particular.

This module shows you how to use a **Comparator** created by the **reverseOrder** method of the **Collections** class to sort a list into reverse natural order. The module also shows you how to use the **reverse** method of the **Collections** class to reverse the order of the elements in a list.

In addition to studying these modules, I strongly recommend that you study the Collections Trail ⁵⁴⁹ in Oracle's Java Tutorials ⁵⁵⁰. The modules in this collection are intended to supplement and not to replace those tutorials.

3.4.27.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the listings while you are reading about them.

3.4.27.3 Preview

In this module, I will teach you how to use a **Comparator** created by the **reverseOrder** method of the **Collections** class to sort a list into *reverse natural order* . I will also teach you how to use the **reverse** method of the **Collections** class to reverse the order of the elements in a list.

3.4.27.4 Generics

The code in this series of modules is written with no thought given to Generics ⁵⁵¹ . As a result, if you copy and compile the code, you will probably get warnings about *unchecked or unsafe operations* .

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.27.5 Discussion and sample code

3.4.27.5.1 Beginning with a quiz

Let's begin with a quiz to test your prior knowledge of the Collections Framework.

What output is produced by the program shown in Listing 1 (p. 1131) (*select one or more answers*) ?

- A. Compiler Error
- B. Runtime Error
- C. Joe Bill Tom JOE BILL TOM
- D. BILL Bill JOE Joe TOM Tom
- E. TOM BILL JOE Tom Bill Joe
- F. Joe Bill Tom JOE TOM BILL
- G. Tom TOM Joe JOE Bill BILL
- H. Joe Bill Tom
- I. None of the above.

public class Comparator07{
    public static void main(String args[]){
        new Worker().doIt();
    }//end main()
}//end class Comparator07

class Worker{
    public void doIt(){
        Iterator iter;
        Collection ref;

        ref = new ArrayList();
        Populator.fillIt(ref);
        iter = ref.iterator();
        while(iter.hasNext()){
            System.out.print(iter.next() + " ");
        }//end while loop
        System.out.println();

        Collections.reverse((List)ref);
        iter = ref.iterator();
        while(iter.hasNext()){
            System.out.print(iter.next() + " ");
        }//end while loop
        System.out.println();

        Comparator aComparator= Collections.reverseOrder();
        Collections.sort((List)ref, aComparator);
        iter = ref.iterator();
        while(iter.hasNext()){
            System.out.print(iter.next() + " ");
        }//end while loop
        System.out.println();

    }//end doIt()
}// end class Worker

class Populator{
    public static void fillIt(Collection ref){
        ref.add("Joe");
        ref.add("Bill");
        ref.add("Tom");
        ref.add("JOE");
        ref.add("BILL");
        ref.add("TOM");
    }//end fillIt()
}//end class Populator
```

Table 3.441

3.4.27.5.1.1 And the answer is ...

The correct answer to the above question is C, E, and G. The output from the program is shown below:

```

Joe Bill Tom JOE BILL TOM
TOM BILL JOE Tom Bill Joe
Tom TOM Joe JOE Bill BILL

```

If that was your answer, you probably already understand most of the material covered in this module. In that case, you might consider skipping this module and moving on to the next module. If that wasn't your answer, you should probably continue with your study of this module.

3.4.27.5.1.2 Similar to previous programs

The overall structure of this program in Listing 1 (p. 1131) is similar to programs that I have discussed in previous modules. Therefore, I will concentrate on those aspects of this program that differentiate it from the programs in previous modules.

3.4.27.5.1.3 A new ArrayList object

The code in Listing 2 (p. 1132) instantiates a new **ArrayList** object and passes that object's reference to a method named **fillIt** where it is populated with the names of several people.

Listing 2 . A new ArrayList object.

```

ref = new ArrayList();
Populator.fillIt(ref);

iter = ref.iterator();
while(iter.hasNext()){
    System.out.print(iter.next() + " ");
} //end while loop

```

Table 3.442

3.4.27.5.1.4 Displays the list contents

The code in Listing 2 (p. 1132) also gets an iterator on the list and uses that iterator to display the contents of the populated list. At that point in the program, the list contains the following elements in the order shown:

Joe Bill Tom JOE BILL TOM

You will recognize this as matching the order in which the elements were added to the list by the **fillIt** method shown in Listing 3 (p. 1133) .

Listing 3 . The fillIt method.

```

class Populator{
public static void fillIt(Collection ref){
    ref.add("Joe");
    ref.add("Bill");
    ref.add("Tom");
    ref.add("JOE");
    ref.add("BILL");
    ref.add("TOM");
} //end fillIt()
} //end class Populator

```

Table 3.443**3.4.27.5.1.5 The ArrayList class**

The **ArrayList** class is one of the concrete class implementations of the Collections Framework. This class implements both the **Collection** interface and the **List** interface. Therefore, it is both a collection and a list, and adheres to the contracts and stipulations of both interfaces.

Here is part of what Oracle has to say about the **ArrayList** class:

"Resizable-array implementation of the List interface. Implements all optional list operations, and permits all elements, including null. ... (This class is roughly equivalent to Vector, except that it is unsynchronized.)"

3.4.27.5.1.6 The reverse method of the Collections class

The call to the **reverse** method shown in Listing 4 (p. 1133) is new to this module.

Listing 4 . The reverse method of the Collections class.

```

Collections.reverse((List)ref);

iter = ref.iterator();
while(iter.hasNext()){
    System.out.print(iter.next() + " ");
} //end while loop

```

Table 3.444

3.4.27.5.2 The Collections class

A previous module discussed the **Collections** class, indicating that the class provides a number of static methods that can be used to manipulate collections. As a refresher, here is part of what Oracle has to say about the **Collections** class:

"This class consists exclusively of static methods that operate on or return collections. It contains polymorphic algorithms that operate on collections, "wrappers", which return a new collection backed by a specified collection, and a few other odds and ends."

You should recall that the **Collections** class is not the same as the **Collection** interface. Don't confuse the two.

3.4.27.5.2.1 The reverse method

One of the static methods in the **Collections** class is the method named **reverse** . Here is part of what Oracle has to say about the **reverse** method:

"Reverses the order of the elements in the specified list."

Pretty simple, huh? But also very useful in some cases.

3.4.27.5.2.2 Contents of the list

After calling the reverse method on the list, the code in Listing 4 (p. 1133) above used an iterator to get and display the contents of the list. The contents of the list at that point in the program were as shown below:

TOM BILL JOE Tom Bill Joe

If you compare this with the previous output, you will see that the locations of the elements in the list are reversed. The element at index 0 was moved to index 5, the element at index 5 was moved to index 0, and the elements in between were moved accordingly.

3.4.27.5.2.3 The reverseOrder method

The code in Listing 5 (p. 1134) is also new to this module. This code calls the static **reverseOrder** method of the **Collections** class and stores the returned value in a reference variable of type **Comparator** .

Listing 5 . The reverseOrder method.

```
Comparator aComparator= Collections.reverseOrder();
```

Table 3.445

3.4.27.5.2.4 What does Oracle have to say about this?

Here is part of what Oracle has to say about the **reverseOrder** method:

"Returns a comparator that imposes the reverse of the natural ordering on a collection of objects that implement the Comparable interface. (The natural ordering is the ordering imposed by the objects' own compareTo method.) This enables a simple idiom for sorting (or maintaining) collections (or arrays) of objects that implement the Comparable interface in reverse-natural-order."

3.4.27.5.2.5 Reverse natural order

You will recall that in several previous modules, I have written a class from which I instantiated a **Comparator** object that was used to sort elements into *reverse natural order*. I chose that sorting order simply because I needed to illustrate how to define such a class, and in my specific cases, *reverse natural order* was relatively easy to implement. (*With a little more effort, I could have implemented a variety of different sorting orders.*)

In my design of those classes, I made no attempt to write a general class that could do the job independently of the type of the elements to be sorted. Rather, my **Comparator** objects tended to be very type specific.

3.4.27.5.3 A type-independent Comparator

What we see here is much more general and sophisticated. The **Comparator** object returned by the **reverseOrder** method can be used to impose a *reverse natural order* on any collection of objects that implement the **Comparable** interface. Thus, the class from which the objects are instantiated doesn't matter, as long as those classes implement the **Comparable** interface. (*I also discussed the Comparable interface in some detail in an earlier module. You may want to refer back to that module to learn more about it.*)

3.4.27.5.3.1 The wonderful world of the Java interface

Here again, we see a manifestation of the benefits of polymorphism as implemented using the Java interface. (*I frequently tell my students that if they don't understand interfaces, they can't possibly understand Java.*)

3.4.27.5.3.2 Sorting the list

The code in Listing 6 (p. 1135) is not new to this module. An earlier module discussed the use of the **sort** method of the **Collections** class, along with a **Comparator** object to sort a list.

<p>Listing 6 . Sorting the list.</p>
<pre>Collections.sort((List)ref, aComparator);</pre>

Table 3.446

3.4.27.5.3.3 Source of Comparator object is new

The thing that is new to this module is the source of the **Comparator** object provided to the **sort** method in Listing 6 (p. 1135).

In the previous modules, the **Comparator** object was obtained by instantiating an object from a class of my own design. Those classes implemented the **Comparator** interface.

In this case, a reference to a **Comparator** object was returned by the call to the **reverseOrder** method of the **Collections** class, and that reference was passed as a parameter to the **sort** method.

3.4.27.5.3.4 Don't know, don't care

The **sort** method doesn't care where the **Comparator** object comes from, as long as it properly implements the **Comparator** interface.

Regardless of the source of the **Comparator** object, the **sort** method will use that object to impose the sorting rules imposed by the **compare** method of the object. In this case, the sorting rules cause the list to be sorted into *reverse natural order* .

3.4.27.5.3.5 The output

The code in Listing 7 (p. 1136) gets and uses an iterator to display the contents of the list following the call to the **sort** method in Listing 6 (p. 1135) .

Listing 7 . Produce the output.

```
iter = ref.iterator();
while(iter.hasNext()){
    System.out.print(iter.next() + " ");
} //end while loop
```

Table 3.447

The output produced by the code in Listing 7 (p. 1136) is shown below:

Tom TOM Joe JOE Bill BILL

You will recognize this as *reverse natural order* for the elements in the list.

3.4.27.6 Run the program

I encourage you to copy the code from Listing 1 (p. 1131) . Paste the code into your Java editor. Then compile and execute it.

Run the program and observe the results. Experiment with the code. Make changes, run the program again, and observe the results of your changes. Make certain that you can explain why your changes behave as they do.

3.4.27.7 Summary

In this module, I taught you how to use a **Comparator** created by the **reverseOrder** method of the **Collections** class to sort a list into *reverse natural order* . The **Comparator** object is generic, and can be used to sort any list of objects that implement the **Comparable** interface.

I also taught you how to use the **reverse** method of the **Collections** class to reverse the order of the elements in a list.

3.4.27.8 What's next?

In the next module, I am going to dig a little deeper into the implications of using the **toArray** method declared in the **Collection** interface.

3.4.29.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java Collections framework in particular.

This module shows you how to use the simpler version of the overloaded **toArray** method that is declared in the **Collection** interface. The module also explains why you need to exercise care when using the elements stored in the resulting array to avoid corrupting the state of the objects referred to by the elements in the collection.

In addition to studying these modules, I strongly recommend that you study the Collections Trail ⁵⁵⁹ in Oracle's Java Tutorials ⁵⁶⁰. The modules in this collection are intended to supplement and not to replace those tutorials.

3.4.29.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the listings while you are reading about them.

3.4.29.3 Preview

In earlier modules, I used the `toArray` method, declared in the `Collection` interface, to copy elements from a collection into an array. However, in those modules, I didn't take the time to fully explain how to use the method. Also, I didn't fully explain the precautions that you need to take when you use the method.

The `Collection` interface declares the following two overloaded versions of the `toArray` method:

```
public Object[] toArray()

public Object[] toArray(Object[] a)
```

In this module, will teach you how to use the first (*simpler*) version of the `toArray` method. I will also show why you need to exercise care when using the elements stored in the array to avoid corrupting the state of the objects referred to by the elements in the collection.

I will teach you how to use the second (*more complex*) version of the `toArray` method in the next module.

3.4.29.4 Generics

The code in this series of modules is written with no thought given to Generics⁵⁶¹ . As a result, if you copy and compile the code, you will probably get warnings about *unchecked or unsafe operations* .

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

3.4.29.5 Discussion and sample code

3.4.29.5.1 Beginning with a quiz

Let's begin with a quiz to test your prior knowledge of the Collections Framework. To take this quiz, examine the program shown in Listing 1 (p. 1148) and write down the output produced by the program.

⁵⁶¹<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

Listing 1 . The program named ToArray01 .

```

//File ToArray01.java
//Copyright 2001, R.G.Baldwin
import java.util.*;
import javax.swing.*;

public class ToArray01{
    public static void main(String args[]){
        new Worker().doIt();
    }//end main()
}//end class ToArray01
//=====//

class Worker{
    public void doIt(){
        Collection ref;

        //Create, populate, and display the
        // contents of a collection
        ref = new LinkedList();
        Populator.fillIt(ref);
        System.out.println("Collection contents");
        showCollection(ref);

        //Get collection contents into the
        // array and display the new
        // contents of the array.
        Object[] array = ref.toArray();
        System.out.println("New array contents");
        showArray(array);

        //Modify a property of an object
        // referred to by one of the
        // elements in the array. Display
        // array contents after
        // modification
        System.out.println("Modified array contents");
        ((JComponent)array[0]).setToolTipText("XX");
        showArray(array);

        //Display the contents of the
        // collection
        System.out.println("Collection contents");
        showCollection(ref);
    }//end doIt()
}//-----//

//Utility method for displaying
// array contents
void showArray(Object[] array){
    for(int i = 0; i < array.length;i++){
        if(array[i] == null){
            System.out.print("null ");
        }else{
            System.out.print(((JComponent)array[i]).

```

Table 3.449

3.4.29.5.1.1 And the answer is ...

The correct answer to the quiz is the program output shown below:

```

Collection contents
B0 B1 L2 B3 B4 L5
New array contents
B0 B1 L2 B3 B4 L5
Modified array contents
XX B1 L2 B3 B4 L5
Collection contents
XX B1 L2 B3 B4 L5

```

If that was your answer, you probably already understand most of the material covered in this module. In that case, you might consider skipping this module and moving on to the next module. If that wasn't your answer, you should probably continue with your study of this module.

3.4.29.5.2 A new LinkedList collection

The code in Listing 2 (p. 1149) creates and populates a new **LinkedList** object and saves the object's reference as the interface type **Collection**. The collection is populated by passing the **LinkedList** object's reference to a method named **fillIt**.

The code in Listing 2 (p. 1149) also displays the contents of the **LinkedList** after it has been populated. The list is displayed by passing the **LinkedList** object's reference to a method named **showCollection**.

Listing 2 . A new LinkedList collection.

<pre> Collection ref; ref = new LinkedList(); Populator.fillIt(ref); System.out.println("Collection contents"); showCollection(ref); </pre>

Table 3.450

3.4.29.5.2.1 The LinkedList class

The **LinkedList** class is one of the concrete class implementations of the *Collections Framework*. This class implements the **Collection** interface and the **List** interface. Thus, it adheres to the contracts and stipulations of the **List** interface.

Here is part of what Oracle has to say about this class:

"Linked list implementation of the List interface. Implements all optional list operations, and permits all elements (including null). In addition ..."

3.4.29.5.2.2 Populating the LinkedList collection

The beginning of the static `fillIt` method, used to populate the collection, is shown in Listing 3 (p. 1150) .

Listing 3 . Beginning of the fillIt method.

```
public static void fillIt(Collection ref){
ref.add(new JButton());
ref.add(new JButton());
ref.add(new JLabel());
ref.add(new JButton());
ref.add(new JButton());
ref.add(new JLabel());
```

Table 3.451

As shown in Listing 3 (p. 1150) , the `fillIt` method begins by calling the `add` method six times in succession, passing references to new anonymous objects as a parameter to the `add` method.

3.4.29.5.2.3 Four buttons and two labels

Four of the objects are instantiated from the class named `JButton` . Two of the objects are instantiated from the class named `JLabel` .

Both `JButton` and `JLabel` belong to the `javax.swing` package. Further, both are subclasses of the class named `JComponent` .

3.4.29.5.2.4 The tooltipText property

Finally, both classes have a property named `tooltipText` , which can be set and accessed by calling the following methods on a reference to the object:

```
void setToolTipText(String text)

String getToolTipText()
```

3.4.29.5.2.5 Why am I using Swing GUI components?

I really don't plan to do anything special with these Swing GUI components. Rather, I chose to use them for illustration purposes simply because they possess the characteristics that I need for this module, and the next module as well. Those characteristics are:

- Both classes subclass the class named `JComponent` (*a common superclass below the Object class*).
- Both classes inherit a property (*tooltipText*) that can be used to identify them later.

3.4.29.5.3 Making the objects distinguishable

After the code in Listing 3 (p. 1150) has been executed, the buttons and labels are indistinguishable on the basis of the *null* value of their `toolTipText` property.

The code in Listing 4 (p. 1151) deals with this issue. This code uses the `setToolTipText` method to store a unique `String` value in the `toolTipText` property of the object referred to by each of the elements in the collection.

Listing 4 . Making the objects distinguishable.

```

        Iterator iter = ref.iterator();
int cnt = 0;
JComponent refVar;

while(iter.hasNext()){
    refVar = (JComponent)iter.next();
    if(refVar instanceof JButton){
        refVar.setToolTipText("B"+cnt++);
    }else{
        refVar.setToolTipText("L" + cnt++);
    }//end else
} //end while loop

} //end fillIt()

```

Table 3.452

3.4.29.5.3.1 Identifying the buttons and labels

In addition to storing a unique value in the `toolTipText` property of the object referred to by each element, the code in Listing 4 (p. 1151) also makes it possible to distinguish between the `JButton` objects and the `JLabel` objects. This is accomplished by including an upper-case "B" in the property value for each `JButton`, and including an upper-case "L" in the property value for each `JLabel` button.

3.4.29.5.3.2 Why populate this way?

This approach to population is, admittedly, a little bit of an overkill for illustrating what I want to illustrate in this program. However, I plan to use the same `fillIt` method in the sample program in the next module, and it won't be an overkill there.

3.4.29.5.3.3 Display the collection

The code in Listing 2 (p. 1149) above calls the `showCollection` method to display the contents of the populated `LinkedList` collection. The `showCollection` method is shown in Listing 5 (p. 1152)

Listing 5 . The showCollection method.

```

    void showCollection(Collection ref){
    Iterator iter = ref.iterator();
    while(iter.hasNext()){
        System.out.print(((JComponent)iter.next()).
                        getToolTipText() + " ");

    }//end while loop
    System.out.println();
    }//end showCollection

```

Table 3.453

By now, you should have no difficulty understanding the code in Listing 5 (p. 1152) . This code gets an iterator on the incoming reference of type **Collection** . The code then uses that iterator to gain access to each element in succession, displaying the **String** value of the **ToolTipText** property belonging to a particular object during each iteration.

3.4.29.5.3.4 Downcast is required

Note that the **next** method of the **Iterator** interface returns a reference to the next element in the collection, as type **Object** . (*Remember, Generics were not used to populate this collection.*)

In order to call the **getToolTipText** method on the returned reference, the reference must be downcast to type **JComponent** . Since both **JButton** and **JLabel** extend **JComponent** , and the **getToolTipText** method is declared in the **JComponent** class, it is not necessary to be concerned as to whether an object is type **JButton** or type **JLabel** to display the value of the **ToolTipText** property. (*This is an example of polymorphic behavior based on class inheritance.*)

3.4.29.5.3.5 The output for the collection

The output produced by the code in Listing 2 (p. 1149) is shown below:

```

Collection contents
B0 B1 L2 B3 B4 L5

```

By examining the "B" and "L" characters in this output, you can identify the **JButton** objects and the **JLabel** objects.

3.4.29.5.4 Copy collection elements into an array

The code in Listing 6 (p. 1153) shows how to use the simple version of the **toArray** method to create an array of type **Object** that contains a copy of each element in the **LinkedList** collection.

Listing 6 . Copy collection elements into an array.

```
Object[] array = ref.toArray();
```

Table 3.454**3.4.29.5.4.1 The toArray method**

Here is some of what Oracle has to say about this version of the **toArray** method:

"Returns an array containing all of the elements in this collection. If the collection makes any guarantees as to what order its elements are returned by its iterator, this method must return the elements in the same order.

The returned array will be "safe" in that no references to it are maintained by this collection. ... The caller is thus free to modify the returned array."

I will have some more to say about the *safe* aspects of the array shortly.

3.4.29.5.4.2 Display the array contents

The code in Listing 7 (p. 1153) calls a method named **showArray** to cause the current contents of the array to be displayed.

Listing 7 . Display the array contents.

```
System.out.println("New array contents");
showArray(array);
```

Table 3.455

The entire **showArray** method is shown in Listing 8 (p. 1153) .

Listing 8 . The showArray method.

```
void showArray(Object[] array){
for(int i = 0; i < array.length;i++){
if(array[i] == null){
System.out.print("null ");
}else{
System.out.print(((JComponent)array[i]).
getToolTipText() + " ");
}
}
}
}

//end else
//end for loop
System.out.println();
}
}

//end showArray()
```

Table 3.456

3.4.29.5.4.3 The `showArray` method

The behavior of the `ShowArray` method is straightforward. The method uses a `for` loop to access each of the elements stored in the array in increasing index order.

A test is made to determine if the element contains a null reference. If so, then the word `null` is displayed for that element. If not, the `getToolTipText` method is used to access and display the value of the `toolTipText` property for each element in the array.

3.4.29.5.4.4 The output for the array

The output produced by the code in Listing 8 (p. 1153) is shown below:

```
New array contents
B0 B1 L2 B3 B4 L5
```

As you can see, (*except for the String that identifies the type of output*) this is an exact match to the output produced when the contents of the collection were displayed.

3.4.29.5.5 How "safe" is the array?

While it is "safe" to modify the contents of the array as explained in the quotation from Oracle earlier, there is still some danger here that you need to be aware of.

Java collections do not store objects. Rather, Java collections store references to objects. In Java, it is entirely possible to have two or more references to the same object.

3.4.29.5.5.1 Array contains copies of references to objects

Each element in the array is a copy of an element in the collection.

Therefore, at this point, for each object being managed by the collection, at least two references exist that refer to that object. One copy is contained in the collection. The other copy is contained in the array.

If you use a reference stored in the array to modify the state of one of those objects, that modification is made to the object that is also referenced by an element in the collection. This may or may not be what you intend. It's not necessarily a problem as long as you understand what is going on and be careful how you use the references stored in the array.

3.4.29.5.5.2 Modifying the state of an object

The code shown in Listing 9 (p. 1155) calls the `setToolTipText` method on the reference stored in the first element in the array to modify the state of the object to which that reference refers. Then the code calls the `showArray` method to display the contents of the array.

Listing 9 . Modifying the state of an object.

```
System.out.println("Modified array contents");
((JComponent)array[0]).setToolTipText("XX");
showArray(array);
```

Table 3.457

The `toolTipText` property value for each of the objects referred to by the remaining elements is left undisturbed.

3.4.29.5.5.3 Display array contents after object modification

The output produced by the code in Listing 9 (p. 1155) is shown below:

```
Modified array contents
XX B1 L2 B3 B4 L5
```

As you can see, except for the first element, this is a match for the display of the array contents before the state of the object referred by the first element was modified. However, the `toolTipText` property for the object referred to by the first element now contains the string "XX", instead of the string "B0" as before.

3.4.29.5.5.4 Display the contents of the collection again

The code in Listing 10 (p. 1155) displays the state of each of the objects referred to by the elements in the `LinkedList` collection.

Listing 10 . Display the contents of the collection again.

```
System.out.println("Collection contents");
showCollection(ref);
```

Table 3.458

The output produced by Listing 10 (p. 1155) is shown below:

```
Collection contents
XX B1 L2 B3 B4 L5
```

As you can see, the state of the object referred to by the reference stored in the first element of the collection is also changed. The `toolTipText` property for that object now contains the string "XX" instead of "B0" as before.

3.4.29.5.6 The bottom line

It is safe to modify the contents of the array, even to replace the references in the array with references to other objects. Such a replacement has no impact on the contents of the collection.

However, it is also possible to use the elements of the array to modify the state of the objects referred to by the elements in the collection.

If this is what you intend to do, that's great. However, if that is not what you intend to do, that may be a problem. So, the bottom line is, be careful what you do with the elements in the array.

3.4.29.6 Run the program

I encourage you to copy the code from Listing 1 (p. 1148) . Paste the code into your Java editor. Then compile and execute it.

Run the program and observe the results. Experiment with the code. Make changes, run the program again, and observe the results of your changes. Make certain that you can explain why your changes behave as they do.

3.4.29.7 Summary

In this module, I taught you how to use the simpler version of the overloaded **toArray** method, declared in the **Collection** interface, to copy the elements from a collection into an array of type **Object** .

I also showed why you need to exercise care when using the elements stored in the array, to avoid corrupting the state of the objects referred to by the elements in the collection.

3.4.29.8 What's next?

In the next module, I will teach you how to use the other, more complex version of the overloaded **toArray** method.

3.4.31.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) in general and the Java Collections framework in particular.

This module shows you how to use the more-complex version of the **toArray** method declared in the **Collection** interface. The module discusses issues regarding the type of the array and the types of the objects referred to by the elements in the collection. The module also discusses issues regarding the relative sizes of the array and the collection. Finally, the module reaffirms that you need to exercise caution when using the elements stored in the array, to avoid corrupting the state of the objects referred to by the elements in the collection.

In addition to studying these modules, I strongly recommend that you study the Collections Trail ⁵⁶⁹ in Oracle's Java Tutorials ⁵⁷⁰. The modules in this collection are intended to supplement and not to replace

⁵⁶⁹<http://docs.oracle.com/javase/tutorial/collections/index.html>

⁵⁷⁰<http://docs.oracle.com/javase/tutorial/index.html>

those tutorials.

3.4.31.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the listings while you are reading about them.

3.4.31.2.1.1 Listings

- Listing 1 (p. 1167) . The program named ToArray02.
- Listing 2 (p. 1168) . A populated array.
- Listing 3 (p. 1169) . A new LinkedList collection.
- Listing 4 (p. 1170) . The fillIt method.
- Listing 5 (p. 1171) . Copy collection elements into an array.
- Listing 6 (p. 1176) . Modify an object .

3.4.31.3 Preview

The **Collection** interface declares the following two overloaded versions of the **toArray** method:

```
public Object[] toArray()  
  
public Object[] toArray(Object[] a)
```

In the previous module, I taught you how to use the first (*simpler*) of the two methods. I also discussed the need to exercise care when using the elements stored in the returned array to avoid corrupting the state of the objects referred to by elements in the collection.

In this module, I will teach you how to use the second (*more-complex*) version of the **toArray** method declared in the **Collection** interface. I will discuss issues regarding the type of the array and the types of the objects referred to by the elements in the collection. I will also discuss issues regarding the relative sizes of the array and the collection.

Finally, I will reaffirm that you need to exercise care when using the elements stored in the array, to avoid corrupting the state of the objects referred to by the elements in the collection.

3.4.31.4 Generics

The code in this series of modules is written with no thought given to Generics⁵⁷¹ . As a result, if you copy and compile the code, you will probably get warnings about *unchecked or unsafe operations* .

While you will ultimately need to understand how to use Generics, that is a very complex topic. An understanding of Generics is beyond the scope of this course. Therefore, for purposes of this course, you can simply ignore those warnings.

⁵⁷¹<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

3.4.31.5 Discussion and sample code

3.4.31.5.1 Beginning with a quiz

As has been the case in the last few modules, let's begin with a quiz to test your prior knowledge of the Collections Framework. To take this quiz, examine the program shown in Listing 1 (p. 1167) and write down the output produced by that program.

Listing 1 . The program named ToArray02 .

```

//File ToArray02.java

import java.util.*;
import javax.swing.*;

public class ToArray02{
    public static void main(String args[]){
        new Worker().doIt();
    }//end main()
}//end class ToArray02
//=====//

class Worker{
    public void doIt(){
        Collection ref;

        //Create, populate, and display
        // the contents of an array
        JComponent[] array = new JComponent[8];
        for(int cnt=0;cnt<8;cnt++){
            array[cnt] = new JButton();
            array[cnt].setToolTipText("" + (cnt+10));
        }//end for loop
        System.out.println();
        showArray(array,"Original array contents");

        //Create, populate, and display the
        // contents of a collection
        ref = new LinkedList();
        Populator.fillIt(ref);
        showCollection(ref,"Collection contents");

        //Get collection contents into the
        // array and display the new
        // contents of the array.
        array = (JComponent[])ref.toArray(array);
        showArray(array,"New array contents");

        //Modify a property of an object
        // referred to by one of the
        // elements in the array. Display
        // array contents after
        // modification
        ((JComponent)array[0]).setToolTipText("XX");
        showArray(array,"Modified array contents");

        //Display the contents of the collection
        showCollection(ref,"Collection contents");
    }//end doIt()

Table 3.461

3.4.31.5.1.1 And the answer is ...

The correct answer to the quiz is the program output shown below:

```
Original array contents
10 11 12 13 14 15 16 17
Collection contents
B0 B1 L2 B3 B4 L5
New array contents
B0 B1 L2 B3 B4 L5 null 17
Modified array contents
XX B1 L2 B3 B4 L5 null 17
Collection contents
XX B1 L2 B3 B4 L5
```

If that was your answer, you probably already understand most of the material covered in this module. In that case, you might consider skipping this module and moving on to some more productive activity. If that wasn't your answer, you should probably continue with your study of this module.

3.4.31.5.1.2 Similar to previous program

Except for the use of a different version of the **toArray** method, the overall structure of the program in Listing 1 (p. 1167) is similar to the program in the previous module. Therefore, I will concentrate on those aspects of this program that differentiate it from the program in the previous module.

3.4.31.5.1.3 A populated array

Unlike the program in the previous module, the code in Listing 2 (p. 1168) creates and populates an eight-element array of type **JComponent**. This array will be re-populated by the **toArray** method later in the program. The array is populated with a set of initial element values at this point to make it obvious when it is re-populated (*overwritten elements*) by the **toArray** method later.

Listing 2 . A populated array.

```
JComponent[] array = new JComponent[8];

for(int cnt=0;cnt<8;cnt++){
    array[cnt] = new JButton();
    array[cnt].setToolTipText("" + (cnt+10));
} //end for loop
System.out.println();
showArray(array,"Original array contents");
```

Table 3.462

The **JButton** class, the **JLabel** class, and the **setToolTipText** method were discussed in detail in the previous module, so I won't repeat that discussion here.

3.4.31.5.1.4 Display the array contents

After the array is populated by the code in Listing 2 (p. 1168) , a reference to the array object is passed to the **showArray** method (*also in Listing 2 (p. 1168)*) to display the contents of the array.

With the exception of some minor changes implemented in this program to make the use of the **showArray** method more compact, this is the same **showArray** method used in the previous module. Therefore, I won't discuss that method further in this module. The output produced by the code in Listing 2 (p. 1168) is as follows:

```
Original array contents
10 11 12 13 14 15 16 17
```

As you can see, each of the eight elements in the array was initialized with an easily-recognizable and unique value, (*which may be overwritten by the **toArray** method later*).

3.4.31.5.1.5 A new LinkedList collection

The code in Listing 3 (p. 1169) creates and populates a new **LinkedList** collection. The collection is populated by passing the **LinkedList** object's reference to a method named **fillIt** .

The code in Listing 2 (p. 1168) also displays the contents of the **LinkedList** collection after it has been populated. The list is displayed by passing the **LinkedList** object's reference to a method named **showCollection** .

Listing 3 . A new LinkedList collection.

```
ref = new LinkedList();
Populator.fillIt(ref);
showCollection(ref,"Collection contents");
```

Table 3.463

Except for a couple of minor changes to the **showCollection** method, the code to create, populate, and display the collection is the same as the code in the previous module.

3.4.31.5.1.6 Populating the LinkedList collection

A couple of points regarding the **fillIt** method (*shown in Listing 4 (p. 1170)*) are worthy of note.

Listing 4 . The fillIt method.

```

    public static void fillIt(Collection ref){
ref.add(new JButton());
ref.add(new JButton());
ref.add(new JLabel());
ref.add(new JButton());
ref.add(new JButton());
ref.add(new JLabel());

    Iterator iter = ref.iterator();
    int cnt = 0;
    JComponent refVar;
    while(iter.hasNext()){
        refVar = (JComponent)iter.next();
        if(refVar instanceof JButton){
            refVar.setToolTipText("B"+cnt++);
        }else{
            refVar.setToolTipText("L" + cnt++);
        }//end else
    }//end while loop

}//end fillIt()

```

Table 3.464

The **fillIt** method begins by calling the **add** method six times in succession, passing references to new anonymous objects (of types *JButton* and *JLabel*) as a parameter to the **add** method.

3.4.31.5.1.7 Four buttons and two labels

Four of the objects are instantiated from the class named **JButton** . The other two objects are instantiated from the class named **JLabel** .

Both **JButton** and **JLabel** belong to the **javax.swing** package. Further, both are subclasses of the class named **JComponent** .

3.4.31.5.1.8 The toolTipText property

Finally, both classes have a property named **toolTipText** , which can be set and accessed by calling the following methods on a reference to the object:

```
void setToolTipText(String text)
```

```
String getToolTipText()
```

3.4.31.5.1.9 JButton and JLabel

I chose to use objects of these two classes for illustration purposes simply because they possess the characteristics that I need for this module. Those characteristics are:

- Both classes subclass the class named `JComponent` (a common superclass below the `Object` class).
- Both classes inherit a property (`toolTipText`) that can be used to identify them later.

3.4.31.5.1.10 Making the objects distinguishable

After adding the objects' references to the collection, the code in Listing 4 (p. 1170) uses the `setToolTipText` method to store a unique `String` value in the `toolTipText` property of the object referred to by each of the elements in the collection.

3.4.31.5.1.11 Identifying the buttons and labels

In addition to storing a unique value in the `toolTipText` property of the object referred to by each element, the code in Listing 4 (p. 1170) also makes it possible to distinguish between the `JButton` objects and the `JLabel` objects. This is accomplished by including an upper-case "B" in the property value for each `JButton`, and including an upper-case "L" in the property value for each `JLabel` button.

3.4.31.5.1.12 Display the collection

The code in Listing 3 (p. 1169) above calls the `showCollection` method to display the contents of the populated `LinkedList` collection. The output produced by the code in Listing 3 (p. 1169) is shown below:

```
Collection contents
B0 B1 L2 B3 B4 L5
```

Each term in the output is the `String` value of the `toolTipText` property for a particular object. Hence, there are six terms in the output, one for each element in the collection.

3.4.31.5.1.13 Copy collection elements into an array

Having completed the preliminaries, we have now reached the point that is the main thrust of this module.

The code in Listing 5 (p. 1171) shows how to use the more-complex version of the `toArray` method to copy the elements in the collection into an array.

Listing 5 . Copy collection elements into an array.

```
array = (JComponent[])ref.toArray(array);
showArray(array,"New array contents");
```

Table 3.465

The code in Listing 5 (p. 1171) also causes the contents of the array to be displayed after it receives the elements from the collection.

The first statement in Listing 5 (p. 1171) causes the first seven elements in the array to be overwritten with element values from the collection (*plus one null value*).

The second statement in Listing 5 (p. 1171) causes the contents of the array to be displayed.

3.4.31.5.2 The `toArray` method

The most important thing to note about Listing 5 (p. 1171) is that a reference to an array object is passed as a parameter to the `toArray` method. (*The simpler version of the `toArray` method, discussed in the previous module, doesn't take any parameters.*)

3.4.31.5.2.1 The essential difference

The essential difference between the two overloaded versions of the `toArray` method has to do with the origin of the array into which the `toArray` method copies the elements from the collection.

With the simpler version of the `toArray` method that takes no parameters. The `toArray` method creates a new array object of type `Object`, populates it, and returns that object's reference as type `Object`.

3.4.31.5.2.2 Type is not an issue for the simpler version

Since the new array object is of type `Object`, (*when the rules for Generics are not adhered to*) there are no issues regarding type compatibility between the type of the array and the types of the elements stored in the collection. A reference to an object of any type can be stored in an array of the generic type `Object[]`.

3.4.31.5.2.3 Size is not an issue for the simpler version

Also, since the array is created when it is needed by the simpler version of the `toArray` method, there are also no size issues. The array is created to be of the correct size to contain copies of all of the elements in the collection.

3.4.31.5.3 More-complex version presents some issues

With the more-complex version of the `toArray` method (*shown in Listing 5 (p. 1171)*), the programmer must provide the array object that will be populated by the `toArray` method. In this situation, there are size issues as well as type issues to be dealt with.

3.4.31.5.3.1 The type issue

Here is some of what the Oracle documentation for the `LinkedList` class has to say about the type issue for this version of the `toArray` method:

"Returns an array containing all of the elements in this list in the correct order. The runtime type of the returned array is that of the specified array. ... Throws: `ArrayStoreException` - if the runtime type of (the specified array) is not a supertype of the runtime type of every element in this list.

In other words, the type of the array passed as a parameter to the `toArray` method must be a superclass of the classes from which all of the objects being managed by the collection were instantiated.

3.4.31.5.3.2 Two types of objects in this collection

In this program, the collection is managing objects of the types `JButton` and `JLabel`. Each of these types is a subclass of the class named `JComponent`. For that reason, the type of array that I instantiated and passed to the `toArray` method is `JComponent[]`.

3.4.31.5.3.3 The size issue

Here is some of what the Oracle documentation for the `LinkedList` class has to say about the size issue for this version of the `toArray` method.

"If the list fits in the specified array, it is returned therein. Otherwise, a new array is allocated with the runtime type of the specified array and the size of this list. If the list fits in the specified array with room to spare (i.e., the array has more elements than the list), the element in the array immediately following the end of the collection is set to null. This is useful in determining the length of the list only if the caller knows that the list does not contain any null elements."

3.4.31.5.3.4 So, what did I do?

Knowing all of this in advance, I purposely caused the size of the `JComponent` array to be larger (by two elements) than the number of elements in the collection. Therefore, the array that I passed to the `toArray` method was populated and a reference to that populated array was returned.

(Had my array been smaller than the number of elements in the collection, the `toArray` method would have created and populated a new array of type `JComponent` and would have returned a reference to that new array object. In that case, my array would have been used by the `toArray` method only for the purpose of determining the runtime type of my array.)

3.4.31.5.3.5 More information from Oracle

Here is some additional information about the `toArray` method provided by the Oracle documentation for the `Collection` interface:

"If this collection makes any guarantees as to what order its elements are returned by its iterator, this method must return the elements in the same order."

Because the iterator for a `LinkedList` object returns the elements in increasing index order, the `toArray` method, in this case, copies the element at each index position in the collection into the element at the same index position in the array. Thus, reference values are copied from each element in the collection into the first six elements in the array.

3.4.31.5.4 The output

The output produced by the code in Listing 5 (p. 1171) is shown below:

```
New array contents
B0 B1 L2 B3 B4 L5 null 17
```

You will note that the first six elements in the array match the six elements in the collection (the initial values placed in the array earlier when the array was instantiated have been overwritten).

You will also note that the value of the seventh element in the array (index value 6) has been overwritten with a null reference.

3.4.31.5.4.1 Demonstrates same array was used

Note finally that the last element in the array was not overwritten. It still contains the value placed there when the array object was instantiated. This demonstrates that the array that I passed to the `toArray` method was populated with the collection data, and a reference to that array was returned by the `toArray` method.

3.4.31.5.4.2 What if the array was too small?

Had my array been too small, it would have been discarded by the `toArray` method. The `toArray` method would have created and populated a new array object of the correct size and runtime type, and would have returned a reference to that new array.

3.4.31.5.4.3 Not difficult to demonstrate

Although this is not demonstrated by this program, it is easy to modify the program to demonstrate this feature.

A `String` representation of the array object can be displayed using a `System.out.println(array)` statement before and after the array is passed to the `toArray` method.

3.4.31.5.4.4 Array as large as or larger than collection

For the cases where my array contained six, seven, or eight elements, and the collection contained six elements, the `String` representations of the array object before and after the call to the `toArray` method were the same. For one case, those `String` representations were as follows:

```
[Ljava.swing.JComponent;@49ba38
 [Ljava.swing.JComponent;@49ba38
```

In other words, the reference variable named `array` referred to the same array object before and after the call to the `toArray` method.

3.4.31.5.4.5 Array smaller than the collection

When I reduced the size of the array to five elements, keeping the size of the collection at six elements, the before and after `String` representations of the array object were as follows:

```
[Ljava.swing.JComponent;@506411
 [Ljava.swing.JComponent;@21807c
```

In this case, the reference to the array object returned by the `toArray` method was different from the reference that was passed to the `toArray` method. In other words, the returned reference referred to a different array object than was referred to by the reference that was passed to the `toArray` method.

3.4.31.5.5 Modify an object

As in the program in the previous module, the code shown in Listing 6 (p. 1176) modifies the value of the **toolTipText** property of the object whose reference is stored in index 0 of the array.

Listing 6 . Modify an object .

```

        ((JComponent)array[0]).setToolTipText("XX");
    showArray(array,"Modified array contents");

    showCollection(ref,"Collection contents");

```

Table 3.466

The code in Listing 6 (p. 1176) also displays the contents of the array and the contents of the collection after the modification is made.

The output produced by the code in Listing 6 (p. 1176) is shown below:

```

Modified array contents
XX B1 L2 B3 B4 L5 null 17
Collection contents
XX B1 L2 B3 B4 L5

```

3.4.31.5.5.1 Now for the caution

Note that the value of the `toolTipText` property of the object referred to by the reference at index 0 of the array, and the same property of the object referred to by the reference at index 0 of the collection was overwritten by "XX". (*This is true because both references refer to the same object.*)

This is the case regardless of which version of the `toArray` method is used. Therefore, the same cautions discussed in the previous module apply here as well.

3.4.31.6 Run the program

I encourage you to copy the code from Listing 1 (p. 1167) , Paste the code into your Java editor. Then compile and execute it.

Run the program and observe the results. Experiment with the code. Make changes, run the program again, and observe the results of your changes. Make certain that you can explain why your changes behave as they do.

3.4.31.7 Summary

In this module, I taught you how to use the more-complex version of the two overloaded versions of the `toArray` method, declared in the `Collection` interface, to copy the elements from a collection into an array of type `JComponent` .

I discussed issues regarding the type of the array and the type of the objects referred to by the elements in the container. I also discussed issues regarding the size of the array as compared to the number of elements in the collection.

Finally, I reaffirmed that you need to exercise care when using the elements stored in the array, to avoid corrupting the state of the objects referred to by the elements in the collection.

3.4.31.8 What's next?

For now, at least, this module concludes the series of modules on the Java Collections Framework. If I have time later, I will come back and add more modules to teach you how to use the **Map** and **SortedMap** interfaces, and the concrete class implementations of those interfaces.

This page is included in the following Books:

- *Object-Oriented Programming (OOP) with Java* ⁵⁷⁸

3.5.1.1 ITSE 2321 Object-Oriented Programming - Practice Group 1

- Java and Media Library Version Requirements (p. 1187)
- Input Image Files (p. 1187)
- Solution source code files (p. 1187)
- Output Images (p. 1187)

 - Program 4 (p. 1195)
 - Program 5 (p. 1197)
- Miscellaneous Information (p. 1200)

3.5.1.1.1 Java and Media Library Version Requirements

Your programs must be compatible with Oracle's Standard Edition JDK Version 1.7 or later.

Some of the programs in this group require you to use the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library ⁵⁷⁹ .

3.5.1.1.2 Input Image Files

Links are provided within the individual program specifications for downloading any image files that may be required to write, compile, and test your programs.

3.5.1.1.3 Solution source code files

Links are provided within the individual program specifications for downloading source code files that contain the programming solutions. You can compile and execute those programs using procedures described in Java OOP: The Guzdial-Ericson Multimedia Class Library ⁵⁸⁰ .

3.5.1.1.4 Output Images

Your output image(s) must match my output image(s) in every respect including color, size, position, etc. Don't forget to display your name in the output image(s) as shown.

⁵⁷⁹<http://cnx.org/content/m44148/latest/>

⁵⁸⁰<http://cnx.org/content/m44148/latest/>

3.5.1.1.5 New Classes

You may define new classes and add import directives as needed to cause your programs to behave as required, but you may not modify the class definitions for the given classes named ProbXX.

3.5.1.1.6 Hints

For some of the programs, you may first need to deduce the algorithm used to transform the input image into the output image, and then write a working program that implements that algorithm. In some cases, you may need to compare numeric color values for corresponding pixels in the input and output images in order to deduce the algorithm.

You can obtain those color values using the following procedure:

1. Click on the input image file link(s) and use the capabilities of your browser to download and save the image file(s).
2. Click on the Java solution source code link(s) and use the capabilities of your browser to download and save the source code file(s).
3. If necessary, replace calls to the `show` method in my source code with calls to the `explore` method to force the program to display the output images in a **PictureExplorer** window.
4. Write, compile, and execute a simple Java program that will display each input image file in a **PictureExplorer** window.
5. Use the input and output **PictureExplorer** windows to compare the input and output color values on a pixel by pixel basis.

In addition to the hints listed above, I will precede the detailed specifications for each program with a discussion that contains hints about the concepts and skills that you will probably need to successfully write the program.

In order to write this or any other Java program of substance, you will need to know how to use⁵⁸¹ the Java Platform, Standard Edition API Specification⁵⁸² as well as the documentation for the Guzdial-Ericson Multimedia Class Library⁵⁸³.

You may find other useful hints in my online tutorials and slides for this course as well as in the YouTube video lectures for this course.

3.5.1.1.7 Testing Your Programs

You can compile and execute your program by following the instructions given at Java OOP: The Guzdial-Ericson Multimedia Class Library⁵⁸⁴.

3.5.1.1.8 Program Specifications

3.5.1.1.8.1 Program 1
