3.5.1.1.8.3 Program 3

Discussion

The following is a non-exhaustive list of concepts that you need to understand along with knowledge and skills that you need to possess in order to successfully write this program and/or understand the given solution in Prob03.java⁶³³. Some of these items are general in nature and some are specific to the use of Ericson's multimedia library. I won't repeat the items listed above. Instead, I will concentrate on new concepts, knowledge, and skills not included in the above lists.

There are at least two alternative ways to write a program that will satisfy these requirements.

Both alternatives

- How to design and implement an algorithm that will transform Prob03.jpg⁶³⁴ into the required output image shown in Figure 3 (p. 1194).

Alternative 1

⁶³³<http://cnx.org/content/m44252/latest/Prob03.java>

⁶³⁴<http://cnx.org/content/m44252/latest/Prob03.jpg>

- How to create a new one-dimensional array object ⁶³⁵ of type `Pixel[]` and populate it with references to all of the `Pixel` objects encapsulated in a `Picture` object.
- How to use some complicated indexing arithmetic ⁶³⁶ in conjunction with the one-dimensional array mentioned above to apply the required algorithm.

Alternative 2

- How to use a nested loop structure ⁶³⁷ to achieve the same result.
- How to use a cast operator ⁶³⁸ .

Listing 3 - Write the Java application described below.

```

/*File Prob03 Copyright 2012 R.G.Baldwin
Write a program named Prob03 that uses the class definition shown below and Ericson's media library
along with the image file named Prob03.jpg 639 to produce the graphic output image shown in Figure 3
(p. 1194) below.
Click Prob03.java 640 to download a Java source file containing the solution to this program.
In addition to the output, your program must display your name and the other text shown below on the
command-line screen:

Display your name here.
Picture, filename Prob03.jpg height 274 width 365

*****/
public class Prob03{
    //DO NOT MODIFY THE CODE IN THIS CLASS DEFINITION.
    public static void main(String[] args){
        Prob03Runner obj = new Prob03Runner();
        obj.run();
        System.out.println(obj.getPicture());
    }//end main
} //end class Prob03
//End program specifications.

```

Table 3.471

Figure 3 - Required output image for Prob03.

⁶⁴⁰<http://cnx.org/content/m44252/latest/Prob03.java>

3.5.1.1.8.4 Program 4

Discussion

The following is a non-exhaustive list of concepts that you need to understand along with knowledge and skills that you need to possess in order to successfully write this program and/or understand the given solution in Prob04.java⁶⁴¹. Some of these items are general in nature and some are specific to the use of Ericson's multimedia library. I won't repeat the items listed above. Instead, I will concentrate on new concepts, knowledge, and skills not included in the above lists.

- How to design and implement an algorithm that will transform Prob04.jpg⁶⁴² into the image shown in Figure 4 (p. 1196).
- Similarities and differences between classes and interfaces⁶⁴³.
- The different types under which you can store an object's reference when the class from which the object was instantiated extends a class and implements one or more interfaces.

⁶⁴¹ <http://cnx.org/content/m44252/latest/Prob04.java>

⁶⁴² <http://cnx.org/content/m44252/latest/Prob04.jpg>

⁶⁴³ <http://cnx.org/content/m44195/latest/>

- The kinds of new relationships that are created when a class implements one or more interfaces.
- The implications of inheriting one or more abstract methods.
- The significance of all interface methods being implicitly abstract.
- That **DigitalPicture** is an interface ⁶⁴⁴ and is not a class in Ericson's library.
- The relationship that exists between the **DigitalPicture** interface and the **Picture** class.
- The circumstances under which an accessor method can return a reference to an object as type **DigitalPicture** .
- The difference between displaying a **Picture** object with the **show** and **explore** methods.

Listing 4 - Write the Java application described below.

```

/*File Prob04 Copyright 2012 R.G.Baldwin
Write a program named Prob04 that uses the class definition shown below and Ericson's media library
along with the image file named Prob04.jpg 645 to produce the graphic output image shown in Figure 4
(p. 1196) below.
Click Prob04.java 646 to download a Java source file containing the solution to this program.
In addition to the output image, your program must display your name and the other text shown below
on the command-line screen:

Display your name here.
Picture, filename Prob04.jpg height 274 width 365
*****/
public class Prob04{
    //DO NOT MODIFY THE CODE IN THIS CLASS DEFINITION.
    public static void main(String[] args){
        Prob04Runner obj = new Prob04Runner();
        DigitalPicture digitalPicture =
                                obj.getDigitalPicture();
        System.out.println(digitalPicture);
        digitalPicture.show();
    }//end main
} //end class Prob04
//End program specifications.

```

Table 3.472

⁶⁴⁶<http://cnx.org/content/m44252/latest/Prob04.java>

3.5.1.1.8.5 Program 5

Discussion

The following is a non-exhaustive list of concepts that you need to understand along with knowledge and skills that you need to possess in order to successfully write this program and/or understand the given solution in Prob05.java⁶⁴⁷. Some of these items are general in nature and some are specific to the use of Ericson's multimedia library. I won't repeat the items listed above. Instead, I will concentrate on new concepts, knowledge, and skills not included in the above lists.

- How to design and implement an algorithm that will transform Prob05a.jpg⁶⁴⁸ and Prob05b.jpg⁶⁴⁹ into the images shown in Figure 5 (p. 1198) and Figure 6 (p. 1199).
- What it means for the method named `getDigitalPictures` to return a reference to an object as type `DigitalPicture[]`⁶⁵⁰.
- What you can do with a reference of type `DigitalPicture[]`.
- The implications of the fact that calling the `show` method each of the elements of the array of type `DigitalPicture[]` produces a different output image.

Listing 5 - Write the Java application described below.

continued on next page

⁶⁴⁸<http://cnx.org/content/m44252/latest/Prob05a.jpg>

⁶⁴⁹<http://cnx.org/content/m44252/latest/Prob05b.jpg>

⁶⁵⁰http://cnx.org/content/m44198/latest/#Listing_1

```

/*File Prob05 Copyright 2012 R.G.Baldwin
Write a program named Prob05 that uses the class definition shown below and Ericson's media library
along with the image files named Prob05a.jpg 651 and Prob05b.jpg 652 to produce the pair of graphic
output images shown in Figure 5 (p. 1198) and Figure 6 (p. 1199) below.
Note that unless you know how to position the output images on the screen, they will both end up in the
upper-left corner of the screen with one image partially or completely covering the other image. Use your
mouse to drag and separate the images.
Click Prob05.java 653 to download a Java source file containing the solution to this program.
In addition to the output images mentioned above, your program must display your name and the other
text shown below on the command-line screen:

```

```

Display your name here.
Picture, filename Prob05b.jpg height 309 width 412
Picture, filename Prob05a.jpg height 274 width 365
*****/
public class Prob05{
    //DO NOT MODIFY THE CODE IN THIS CLASS DEFINITION.
    public static void main(String[] args){
        Prob05Runner obj = new Prob05Runner();
        DigitalPicture[] digitalPictures =
            obj.getDigitalPictures();

        System.out.println(digitalPictures[0]);
        digitalPictures[0].show();

        System.out.println(digitalPictures[1]);
        digitalPictures[1].show();
    }//end main
} //end class Prob05
//End program specifications.

```

3.5.2 Java OOP: ITSE 2321 Practice Group 2⁶⁵⁴

Revised: Fri Apr 08 17:48:44 CDT 2016

This page is included in the following Books:

- *ITSE 2321 - Object-Oriented Programming (Java)* ⁶⁵⁵
- *Object-Oriented Programming (OOP) with Java* ⁶⁵⁶

3.5.2.1 ITSE 2321 Object-Oriented Programming - Practice Group 2

- Java and Media Library Version Requirements (p. 1201)
- Input Image Files (p. 1201)
- Solution source code files (p. 1201)
- Output Images (p. 1201)
- New Classes (p. 1202)
- Hints (p. 1202)
- Testing Your Programs (p. 1202)
- Program Specifications (p. 1202)
 - Program 1 (p. 1202)
 - Program 2 (p. 1204)
 - Program 3 (p. 1206)
 - Program 4 (p. 1208)
 - Program 5 (p. 1210)
- Miscellaneous Information (p. 1212)

3.5.2.1.1 Java and Media Library Version Requirements

Your programs must be compatible with Sun's Standard Edition JDK Version 1.7 or later.

Some of the programs in this group require you to use the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library ⁶⁵⁷ .

3.5.2.1.2 Input Image Files

Links are provided within the individual program specifications for downloading any image files that may be required to write, compile, and test your programs.

3.5.2.1.3 Solution source code files

Links are provided within the individual program specifications for downloading source code files that contain the programming solutions. You can compile and execute those programs using procedures described in Java OOP: The Guzdial-Ericson Multimedia Class Library ⁶⁵⁸ .

3.5.2.1.4 Output Images

Your output image(s) must match my output image(s) in every respect including color, size, position, etc. Don't forget to display your name in the output image(s) as shown.

⁶⁵⁴This content is available online at <<http://cnx.org/content/m44254/1.9/>>.

⁶⁵⁵<http://cnx.org/contents/dzOvxPFw>

⁶⁵⁶http://cnx.org/contents/-2RmHFs_

⁶⁵⁷<http://cnx.org/content/m44148/latest/>

⁶⁵⁸<http://cnx.org/content/m44148/latest/>

3.5.2.1.5 New Classes

You may define new classes and add import directives as needed to cause your programs to behave as required, but you may not modify the class definitions for the given classes named ProbXX.

3.5.2.1.6 Hints

For some of the programs, you may first need to deduce the algorithm used to transform the input image into the output image, and then write a working program that implements that algorithm. In some cases, you may need to compare numeric color values for corresponding pixels in the input and output images in order to deduce the algorithm.

You can obtain those color values using the following procedure:

1. Click on the input image file link(s) and use the capabilities of your browser to download and save the image file(s).
2. Click on the Java solution source code link(s) and use the capabilities of your browser to download and save the source code file(s).
3. If necessary, replace calls to the `show` method in my source code with calls to the `explore` method to force the program to display the output images in a **PictureExplorer** window.
4. Write, compile, and execute a simple Java program that will display each input image file in a **PictureExplorer** window.
5. Use the input and output **PictureExplorer** windows to compare the input and output color values on a pixel by pixel basis.

In addition to the hints listed above, I will precede the detailed specifications for each program with a discussion that contains hints about the concepts and skills that you will probably need to successfully write the program.

In order to write this or any other Java program of substance, you will need to know how to use⁶⁵⁹ the Java Platform, Standard Edition API Specification⁶⁶⁰ as well as the documentation for the Guzdial-Ericson Multimedia Class Library⁶⁶¹.

You may find other useful hints in my online tutorials and slides for this course as well as in the YouTube video lectures for this course.

3.5.2.1.7 Testing Your Programs

You can compile and execute your program by following the instructions given at Java OOP: The Guzdial-Ericson Multimedia Class Library⁶⁶².

3.5.2.1.8 Program Specifications

3.5.2.1.8.1 Program 1

Discussion

The following is a non-exhaustive list of concepts that you need to understand along with knowledge and skills that you need to possess in order to successfully write this program and/or understand the given solution in Prob01.java⁶⁶³. Some of these items are general in nature and some are specific to the use of Ericson's multimedia library. I won't repeat the items that were listed with the programs in Practice Group 1⁶⁶⁴. Instead, I will concentrate on new concepts, knowledge, and skills not included in previous lists.

⁶⁵⁹<http://cnx.org/content/m45117/latest/>

⁶⁶²<http://cnx.org/content/m44148/latest/>

⁶⁶³<http://cnx.org/content/m44254/latest/Prob01.java>

⁶⁶⁴<http://cnx.org/content/m44252/latest/>

- How to design and implement an algorithm that will transform the original image ⁶⁶⁵ into the image shown in Figure 1 (p. 1203) .
- How to instantiate an object and call a method on that object in a single statement ⁶⁶⁶ .
- How methods belonging to an object call other methods ⁶⁶⁷ belonging to the same object.
- How to call a method on an object to modify the object saving only ⁶⁶⁸ a reference to the modified object.
- The use of nested loops ⁶⁶⁹ to access and modify image pixels on the basis of the horizontal and vertical coordinates of the pixels.
- How to create a mirror image of a portion of an image about a vertical line ⁶⁷⁰ in the image.
- How to create a mirror image of a portion of an image about a horizontal ⁶⁷¹ line in the image.

Listing 1 - Write the Java application described below.

```

/*File Prob01 Copyright 2012 R.G.Baldwin
Write a program named Prob01 that uses the class definition shown below and Ericson's media library
along with the image file named Prob01.jpg 672 to produce the graphic output image shown in Figure 1
(p. 1203) below.
Click Prob01.java 673 to download a Java source file containing the solution to this program.
In addition to the output image, your program must display your name and the other text shown below
on the command-line screen:

    Display your name here.
Picture, filename Prob01.jpg height 240 width 320
*****/
public class Prob01{
    //DO NOT MODIFY THE CODE IN THIS CLASS DEFINITION.
    public static void main(String[] args){
        Picture pic = new Prob01Runner().run();
        System.out.println(pic);
    }//end main method
} //end class Prob01
//End program specifications.

```

3.5.2.1.8.4 Program 4

Discussion

The following is a non-exhaustive list of concepts that you need to understand along with knowledge and skills that you need to possess in order to successfully write this program and/or understand the given solution in Prob04.java⁶⁹⁸. Some of these items are general in nature and some are specific to the use of Ericson's multimedia library. I won't repeat the items that were listed with the programs in Practice Group 1⁶⁹⁹ or earlier programs in this practice group. Instead, I will concentrate on new concepts, knowledge, and skills not included in previous lists.

- How to design and implement an algorithm that will transform Prob04a.bmp⁷⁰⁰, Prob04b.bmp⁷⁰¹, and Prob04c.jpg⁷⁰² into the image shown in Figure 4 (p. 1209).
- How to use one image as a pattern⁷⁰³ to perform modifications on another image.

⁶⁹⁸<http://cnx.org/content/m44254/latest/Prob04.java>

⁶⁹⁹<http://cnx.org/content/m44252/latest/>

⁷⁰⁰<http://cnx.org/content/m44254/latest/Prob04a.bmp>

⁷⁰¹<http://cnx.org/content/m44254/latest/Prob04b.bmp>

⁷⁰²<http://cnx.org/content/m44254/latest/Prob04c.jpg>

⁷⁰³http://cnx.org/content/m44234/latest/#Listing_5

- How to brighten ⁷⁰⁴ the colors of selected pixels in an image.
- How to tint ⁷⁰⁵ the colors of selected pixels in an image.

Listing 4 - Write the Java application described below.

```

/*File Prob04 Copyright 2012 R.G.Baldwin
Write a program named Prob04 that uses the class definition shown below and Ericson's media library
along with the image files named Prob04a.bmp 706, Prob04b.bmp 707, and Prob04c.jpg 708 to produce
the graphic output image shown in Figure 4 (p. 1209) below.
Click Prob04.java 709 to download a Java source file containing the solution to this program.
In addition to the output image, your program must display your name and the other text shown below
on the command-line screen:

Display your name here.
Picture, filename None height 293 width 392
*****/
import java.awt.Color;
public class Prob04{
    //DO NOT MODIFY THE CODE IN THIS CLASS DEFINITION.
    public static void main(String[] args){
        Prob04Runner obj = new Prob04Runner();
        obj.run();
    }//end main
}//end class Prob04
//End program specifications.

```

3.5.2.1.8.5 Program 5

Discussion

The following is a non-exhaustive list of concepts that you need to understand along with knowledge and skills that you need to possess in order to successfully write this program and/or understand the given solution in Prob05.java⁷¹⁰. Some of these items are general in nature and some are specific to the use of Ericson's multimedia library. I won't repeat the items that were listed with the programs in Practice Group 1⁷¹¹ or earlier programs in this practice group. Instead, I will concentrate on new concepts, knowledge, and skills not included in previous lists.

- How to design and implement an algorithm that will transform Prob05a.jpg⁷¹² into the image shown in Figure 5 (p. 1211).
- How to extend a class to make it possible to override one or more methods⁷¹³ belonging to the class.

Listing 5 - Write the Java application described below.

⁷¹³<http://cnx.org/content/m44177/latest/>

```

/*File Prob05 Copyright 2012 R.G.Baldwin
Write a program named Prob05 that uses the class definition shown below and Ericson's media library
along with the image file named Prob05a.jpg714 to produce the graphic output image shown in Figure 5
(p. 1211) below.
Click Prob05.java715 to download a Java source file containing the solution to this program.
In addition to the output images mentioned above, your program must display your name and the other
text shown below on the command-line screen:

Display your name here.
Simple Picture, filename Prob05.jpg height 240 width 320

*****/
public class Prob05{
    //DO NOT MODIFY THE CODE IN THIS CLASS DEFINITION.
    public static void main(String[] args){
        MyPicture pic = new Prob05Runner().run();
        System.out.println(pic);
        pic.addMessage("String",10,50);
        pic.show();
    }//end main method
} //end class Prob05
//End program specifications.

```

3.5.3 Java OOP: ITSE 2321 Practice Group 3⁷¹⁶

Revised: Fri Apr 08 17:49:30 CDT 2016

This page is included in the following Books:

- *ITSE 2321 - Object-Oriented Programming (Java)* ⁷¹⁷
- *Object-Oriented Programming (OOP) with Java* ⁷¹⁸

3.5.3.1 ITSE 2321 Object-Oriented Programming - Practice Group 3

- Java and Media Library Version Requirements (p. 1213)
- Input Image Files (p. 1213)
- Solution source code files (p. 1213)
- Output Images (p. 1213)
- New Classes (p. 1214)
- Hints (p. 1214)
- Testing Your Programs (p. 1214)
- Program Specifications (p. 1215)
 - Program 1 (p. 1215)
 - Program 2 (p. 1216)
 - Program 3 (p. 1219)
 - Program 4 (p. 1221)
 - Program 5 (p. 1222)
- Miscellaneous Information (p. 1223)

3.5.3.1.1 Java and Media Library Version Requirements

Your programs must be compatible with Sun's Standard Edition JDK Version 1.7 or later.

Some of the programs in this group require you to use the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library ⁷¹⁹ .

3.5.3.1.2 Input Image Files

Links are provided within the individual program specifications for downloading any image files that may be required to write, compile, and test your programs.

3.5.3.1.3 Solution source code files

Links are provided within the individual program specifications for downloading source code files that contain the programming solutions. You can compile and execute those programs using procedures described in Java OOP: The Guzdial-Ericson Multimedia Class Library ⁷²⁰ .

3.5.3.1.4 Output Images

Your output image(s) must match my output image(s) in every respect including color, size, position, etc. Don't forget to display your name in the output image(s) as shown.

⁷¹⁶This content is available online at <<http://cnx.org/content/m44255/1.7/>>.

⁷¹⁷<http://cnx.org/contents/dzOvxPFw>

⁷¹⁸http://cnx.org/contents/-2RmHFs_

⁷¹⁹<http://cnx.org/content/m44148/latest/>

⁷²⁰<http://cnx.org/content/m44148/latest/>

3.5.3.1.5 New Classes

You may define new classes and add import directives as needed to cause your programs to behave as required, but you may not modify the class definitions for the given classes named ProbXX.

3.5.3.1.6 Hints

For some of the programs, you may first need to deduce the algorithm used to transform the input image into the output image, and then write a working program that implements that algorithm. In some cases, you may need to compare numeric color values for corresponding pixels in the input and output images in order to deduce the algorithm.

You can obtain those color values using the following procedure:

1. Click on the input image file link(s) and use the capabilities of your browser to download and save the image file(s).
2. Click on the Java solution source code link(s) and use the capabilities of your browser to download and save the source code file(s).
3. If necessary, replace calls to the **show** method in my source code with calls to the **explore** method to force the program to display the output images in a **PictureExplorer** window.
4. Write, compile, and execute a simple Java program that will display each input image file in a **PictureExplorer** window.
5. Use the input and output **PictureExplorer** windows to compare the input and output color values on a pixel by pixel basis.

You may find other useful hints in my online tutorials and slides for this course as well as in the YouTube video lectures for this course.

3.5.3.1.7 Testing Your Programs

You can compile and execute your program by following the instructions given at Java OOP: The Guzdial-Ericson Multimedia Class Library ⁷²¹ .

⁷²¹<http://cnx.org/content/m44148/latest/>

Chapter 4

ITSE2317 - Java Programming (Intermediate)

4.1 Preface

4.1.1 Jy0030: Java OOP: Preface to ITSE 2317¹

Revised: Fri Sep 23 13:08:46 CDT 2016

This page is included in the following Books:

- *ITSE2317 - Java Programming (Intermediate)* ²
- *Object-Oriented Programming (OOP) with Java* ³

4.1.1.1 Table of Contents

- Welcome (p. 1225)
- Essence of OOP (p. 1226)
- Downloads (p. 1226)
- Miscellaneous (p. 1226)

4.1.1.2 Welcome

Welcome to the course material for *ITSE2317 - Java Programming (Intermediate)*, which I teach at Austin Community College ⁴ in Austin, TX.

Information about the course

The college website for this course is: <http://www.austincc.edu/baldwin/> ⁵

As of December 2013, the State of Texas description for this course reads as follows:

"Introduction to object-oriented Java programming including the fundamental syntax and semantics of Java for applications and web applets."

¹This content is available online at <<http://cnx.org/content/m45258/1.11/>>.

²<http://cnx.org/contents/R123r3Lw>

³http://cnx.org/contents/-2RmHF_s_

⁴<http://www.austincc.edu/>

⁵<http://www.austincc.edu/baldwin/>

The prerequisite for the course is ITSE 2321 - Object-Oriented Programming (Java) ⁶ or department approval.

In the event that you enroll in this course without having successfully completed a section of that prerequisite course taught by Prof. Baldwin, or you successfully completed that course under Prof. Baldwin but a significant amount of time has elapsed since you completed the course, you should review the material in the following three Ebooks to make certain that you understand all of the material covered in those Ebooks before embarking on this course:

- Programming Fundamentals with Java ⁷
- Java OOP Self-Assessment ⁸
- ITSE 2321 - Object-Oriented Programming (Java) ⁹

The course covers **three major topics** :

- Generics
- Event Handling
- JavaServer Pages (JSP)

4.1.1.3 Essence of OOP

In addition to the three major topics listed above (p. 1226) , there is also a topic named **Essence of OOP** that contains necessary background material for an understanding of **Event Handling** . This is a continuation of a topic having the same name that begins in the prerequisite course, ITSE 2321 - Object-Oriented Programming (Java) ¹⁰ .

4.1.1.4 Downloads

I encourage you to take advantage of the download options that OpenStax has to offer in order to customize this material for use in your organized courses or for personal self study.

4.1.1.5 Miscellaneous

This section contains a variety of miscellaneous information.

4.2 Essence of OOP

4.2.1 Java1632 The Essence of OOP using Java, Static Initializer Blocks¹¹

Revised: Wed May 11 14:42:52 CDT 2016

This page is included in the following Books:

- *ITSE2317 - Java Programming (Intermediate)* ¹²
- *Object-Oriented Programming (OOP) with Java* ¹³

4.2.1.1 Table of contents

- Preface (p. 1227)
- Tutorial and code links (p. 1227)
- Miscellaneous (p. 1228)

4.2.1.2 Preface

Over the years, I have published a large number of tutorials in the areas of computer programming and digital signal processing (DSP). As I have time available, I am converting the more significant of those tutorials into cnxml code and re-publishing them at cnx.org ¹⁴ .

In the meantime, this is one of the pages in a book titled ITSE2317 - Java Programming (Intermediate) ¹⁵ that presents PDF versions of the original tutorials to make them readily available for Connexions users. When I have time available, I plan to update this tutorial and to re-publish it as a standard page at cnx.org ¹⁶ .

This tutorial may contain internal links to other tutorials that I have written and published somewhere on the web. Those links may, or may not still be good. In any event, if you search cnx.org ¹⁷ for the tutorial by title or by topic, you will probably find a clean copy of the referenced tutorial at cnx.org ¹⁸ . If not, you can probably use a Google Advanced Search ¹⁹ to find a copy somewhere on the web.

4.2.1.3 Tutorial and code links

Click here ²⁰ to download and view the PDF version of this page.

The representation of program code in PDF documents is often very unreliable. Click here ²¹ to download a zip file containing a clean copy of the program code discussed in this tutorial.

¹¹This content is available online at <<http://cnx.org/content/m59577/1.2/>>.

4.2.3.2 Preface

This module is one in a collection of modules designed for teaching *ITSE2317 - Java Programming (Intermediate)* at Austin Community College in Austin, TX.

(Editor's note: As you read this module, you will see that it was originally written around 2003. However, despite many improvements in Java since then, most of what was true then is still true in 2013.)

This module makes several references to my website, which is located at <http://www.dickbaldwin.com/toc.htm>³⁸.

4.2.3.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

4.2.3.2.1.1 Figures

- Figure 1 (p. 1243) . Class files produced when the program is compiled.
- Figure 2 (p. 1244) . Screen output.
- Figure 3 (p. 1244) . Screen output.
- Figure 4 (p. 1244) . Screen output.
- Figure 5 (p. 1244) . Screen output.
- Figure 6 (p. 1244) . Screen output.
- Figure 7 (p. 1245) . Screen output.
- Figure 8 (p. 1245) . Screen output.
- Figure 9 (p. 1245) . Screen output.

³⁸<http://www.dickbaldwin.com/toc.htm>

- Figure 10 (p. 1245) . Screen output.
- Figure 11 (p. 1246) . Screen output.
- Figure 12 (p. 1246) . Screen output.
- Figure 13 (p. 1246) . Screen output.
- Figure 14 (p. 1246) . Screen output.

- Figure 16 (p. 1247) . Screen output.

4.2.3.2.1.2 Listings

- Listing 1 (p. 1247) . The main method.
- Listing 2 (p. 1247) . The class named X.
- Listing 3 (p. 1248) . Beginning of the top-level class named A.
- Listing 4 (p. 1248) . Constructor for class A.
- Listing 5 (p. 1248) . Beginning of the member class named B.
- Listing 6 (p. 1249) . Constructor for class B.
- Listing 7 (p. 1249) . Beginning of the member class named C.
- Listing 8 (p. 1249) . Beginning of constructor for class C.
- Listing 9 (p. 1250) . The private member class named D.
- Listing 10 (p. 1250) . More constructor code for class C.
- Listing 11 (p. 1250) . More constructor code for class C.
- Listing 12 (p. 1250) . The method named bShow.
- Listing 13 (p. 1251) . The method named aShow.
- Listing 14 (p. 1251) . Beginning of the cShow method.
- Listing 15 (p. 1251) . More cShow method code.
- Listing 16 (p. 1251) . Call the aShow method.
- Listing 17 (p. 1252) . More cShow method code.
- Listing 18 (p. 1252) . More cShow method code.
- Listing 19 (p. 1252) . More cShow method code.
- Listing 20 (p. 1253) . More cShow method code.
- Listing 21 (p. 1253) . More cShow method code.
- Listing 22 (p. 1253) . More cShow method code.
- Listing 23 (p. 1253) . Overridden toString method in class C.
- Listing 24 (p. 1254) . More cShow method code.
- Listing 25 (p. 1254) . Complete program listing.

4.2.3.3 Preview

4.2.3.3.1 What can you include in a class definition ?

There are several different kinds of items that can be contained in a class definition. As you learned in the early modules in this series, the list includes:

- Static variables
- Instance variables
- Static methods
- Instance methods
- Constructors

As you can learn at <http://www.dickbaldwin.com/toc.htm> ³⁹, the list also includes:

³⁹<http://www.dickbaldwin.com/toc.htm>

- Static initializer blocks
- Instance initializers

Can also contain other class definitions

In this and the next two modules, you will learn that a class definition can also contain the following three kinds of **inner classes** :

- Member classes
- Local classes
- Anonymous classes

A class can also contain **Nested top-level classes and interfaces** , which you can learn about at <http://www.dickbaldwin.com/toc.htm> ⁴⁰ .

(Note that it is questionable whether a nested top-level class or interface should be referred to as an inner class, because an object of a nested top-level class can exist in the absence of an object of the enclosing class. Regardless of whether the term inner class applies, a nested top-level class is defined within the definition of another class, so its definition is internal to the definition of another class.)

This module will be dedicated to an explanation of **member classes** . Subsequent modules will explain the other two types of inner classes in the above list (p. 1232) .

4.2.3.3.2 What is a member class ?

A *member class* is a class that is defined inside the definition of another class, (*without the use of the static modifier as is the case with a nested top-level class*).

An object of the member class must be internally linked to an object of the enclosing class, (*which is not the case with a nested top-level class*).

Thus, a member class is truly an inner class. (*An object of the member class cannot exist in the absence of an object of the enclosing class.*)

4.2.3.3.3 What about a member interface ?

Interfaces defined within classes are implicitly static. This means that they are always *top-level*. There is no such thing as a member interface, a local interface, or an anonymous interface.

4.2.3.3.4 Why use member classes ?

Probably the most important benefit of member classes has to do with accessing the other members of enclosing classes. The methods of a member class have direct access to all the members of the enclosing classes, including private members. Thus the use of member classes can eliminate the requirement to connect objects together via constructor parameters.

This is particularly useful in those cases where there is no reason for an object of a member class to exist in the absence of an object of the enclosing class, and where the methods of the object of the member class need access to members of the object of the enclosing class.

Data structures and iterators

For example, there is usually no reason for an **Iterator** object to exist in the absence of the data-structure object for which it is designed to provide iterator services. Also, the iterator object usually needs to have ready access to the members of the data-structure object, some or all of which may be private. Thus, a class from which an **Iterator** object can be constructed is a good candidate for inclusion as a member class in the class from which the associated data-structure object is instantiated.

⁴⁰<http://www.dickbaldwin.com/toc.htm>

Listener objects

Another common use for inner classes is in the definition of classes from which listener objects (*which listen for events fired by other objects*) are instantiated. (*However, it may be more common to use anonymous classes than member classes for this purpose.*)

What does Flanagan have to say?

Here is how David Flanagan, author of *Java in a Nutshell*, summarizes his discussion of member classes.

*"A class defined as a member (non-static) of another. Each instance has an enclosing instance, and can use its members. New syntax for **this** , **new** , and **super** . Cannot have **static** members. Cannot have same name as containing class."*

According to Flanagan, the main features of member classes are:

- Every instance of a member class is internally associated with an instance of the class that defines or contains the member class.
- The methods of a member class can implicitly refer to the fields defined within the member class, as well as those defined by any enclosing class, including **private** fields of the enclosing class.

4.2.3.3.5 Smoke and mirrors

Every class definition in a Java program, including nested top-level classes, member classes, local classes, and anonymous classes, produces a class file when the program is compiled. According to Flanagan,

"The Java Virtual Machine knows nothing about nested top-level classes and interfaces or the various types of inner classes. Therefore, the Java compiler must convert these new types into standard non-nested class files that the Java interpreter can understand. This is done through source code transformations that insert \$ characters into nested class names. These source code transformations may also insert hidden fields, methods, and constructor arguments into the affected classes."

A reference to the containing object

For example, the compiler automatically inserts a private instance variable in the member class to hold a reference to the containing object. It also inserts a hidden argument in all constructors for the member class, and passes the containing object's reference to the constructor for the member class. The modified constructor saves that reference in the private instance variable of the object of the member class. Thus each object instantiated from the member class contains a private reference to the containing object.

Accessing private members

In those cases where it is necessary for an object of the member class to access private members of the containing object, the compiler automatically creates and uses accessor methods that make such access possible.

Similar to your code

The bottom line is that the code that is automatically produced by the compiler is probably very similar to code that you would write if you were writing the program using only of top-level classes. The good news is that you don't have to write that extra code, and you don't have to maintain it. The extra code is written for you, and if you modify your class structure, the extra code is automatically modified accordingly.

4.2.3.4 Discussion and sample code

The paragraphs that follow will explain a program named **InnerClasses06** , which is designed specifically to illustrate various characteristics of member classes. I will discuss the program in fragments. A complete listing is shown in Listing 25 (p. 1254) near the end of the module.

This program illustrates the use of member classes. The program consists of a total of six classes:

- Top-level classes named
 - InnerClasses06
 - A
 - X
- Member classes named
 - B
 - C
 - D

When compiled, the program produces the class files shown in Figure 1 (p. 1243) .

4.2.3.4.1 Class containment hierarchy

Once you understand the class file naming convention, you can determine from the file names in Figure 1 (p. 1243) that class B is a member class of class A.

(The class file named A\$B.class indicates that the class named B is a member of the class named A.)

Similarly, class C is a member of class B, and class D is a private member of class C.

(However, you cannot tell from the class file names that class D is private.)

4.2.3.4.2 Behavior of the program

An object is instantiated from the class named A. This makes it possible to instantiate an object of the member class named B. The object of the class named B is internally linked to the object of the class named A.

(This causes the instance variable, constructor parameter, and accessor methods discussed above to be automatically created to link the object of the class named B to the object of the class named A.)

The object of the class named B is used to instantiate an object of the member class named C. This object of the class C is linked to the object of the class named B.

Instantiate additional objects of classes A and B, plus an object of class D

When the object of the class named C is instantiated, the constructor for that class instantiates separate objects of the classes named A and B, and also instantiates an object of the **private** member class named D.

(We will see later that the new and separate object of the class named B continues to be internally linked to the original object of the Class named A, and is not internally linked to the new object of the class named A.)

Instantiation of the object of class D illustrates the use of private member classes.

(Note that while top-level classes cannot be private, member classes can be private.)

Perform a variety of operations

A variety of operations are performed from within the methods belonging to the object of the class C to illustrate the attributes and behavior of objects instantiated from member classes.

Comments in the code explain the purpose of each of those operations.

Many of those operations produce screen output, which will be shown in conjunction with the code that produced the output.

4.2.3.4.3 Structure of the program

The main method

The **main** method of the controlling class named **InnerClasses06** , is shown in Listing 1 (p. 1247) .

The code in Listing 1 (p. 1247) instantiates an object of the member class named C and calls the method named **cShow** on that object.

(Note that it is necessary to first instantiate objects of the enclosing classes named A and B before the object of the member class named C can be instantiated.)

An independent top-level class named X

Listing 2 (p. 1247) shows the definition of an independent top-level class named X.

This class will be extended by the class named C, which is a member of the class named B, which is a member of the class named A. This will illustrate that the inheritance hierarchy is independent of the containment hierarchy.

As you can see in Listing 2 (p. 1247) , the class named X overrides the **toString** method to identify itself when called.

*(The **toString** method is automatically called whenever an object's reference is passed as a parameter to the **println** method.)*

The top-level class named A

Listing 3 (p. 1248) shows the beginning of the top-level class named A.

Listing 3 (p. 1248) shows the declaration of two instance variables and three class variables in the class named A. All of the variables are private, and some are initialized when declared. The three class variables will be used to maintain a count of the number of objects instantiated from the classes named A, B, and C.

*(Because member classes **cannot contain static members** , the counter variables for the member classes named B and C were placed in the top-level class named A instead of placing them in their respective class definitions.)*

Constructor for class A

Listing 4 (p. 1248) shows the constructor for the top-level class named A.

Whenever an object of the class named A is instantiated, the constructor does the following:

- Saves the value of an incoming parameter in a private instance variable named **aVar** .
- Increments the object counter named **objCntA** , maintaining a count of the objects instantiated from class A.
- Saves the value of the object counter in an instance variable named **objNumber** to identify the specific object.
- Displays a message showing the identification of the object being instantiated.

The screen output

The code in Listing 1 (p. 1247) instantiates a new object of the class named A, passing the integer value 1 as a parameter to the constructor. As a result, the code in the constructor shown in Listing 4 (p. 1248) produces the screen output shown in Figure 2 (p. 1244) .

As you can see from the value of the object counter in Figure 2 (p. 1244) , this is the first object instantiated from the class named A.

(The value passed, as a parameter to the constructor, is not displayed by the code in the constructor. That value will be displayed later.)

The method named aShow

The class named A also defines a private method named `aShow` . I will defer my discussion of that method until later when it is called.

The member class named B

Listing 5 (p. 1248) shows the beginning of the member class named B.

If you examine the complete listing of the program in Listing 25 (p. 1254) , you will see that the class named B is defined internal to the class named A. In other words, the beginning of the definition of the class named B appears before the curly brace that signals the end of the definition of the class named A. Thus, the class named B is a member class of the class named A.

The code in Listing 5 (p. 1248) declares two private instance variables and initializes one of them.

Constructor for class B

Listing 6 (p. 1249) shows the entire constructor for the class named B.

Whenever an object of the class named B is instantiated, the constructor does the following:

- Saves the value of an incoming parameter in a private instance variable named `bVar` .
- Increments the object counter named `objCntB` , which is a class variable of the containing top-level class named A, maintaining a count of objects instantiated from class B.
- Saves the value of the object counter in an instance variable named `objNumber` to identify the specific object.
- Displays a message showing the identification of the object being instantiated.

The screen output

Listing 1 (p. 1247) shows the instantiation of a new object of class B, immediately following the instantiation of an object of class A.

The object instantiated from the member class named B is linked to the object instantiated from the top-level class named A.

The constructors for the classes named A and B produce the two lines of output shown in Figure 3 (p. 1244) , the first of which is a repeat of the output shown in Figure 2 (p. 1244) .

The method named bShow

The class named B also defines a private method named `bShow` . As with the method named `aShow` mentioned earlier, I will defer a discussion of `bShow` until later when it is called.

The member class named C

Listing 7 (p. 1249) shows the beginning of a member class named C.

Class C is a member of the class named B. In other words, the beginning of the definition of the class named C begins before the curly brace that ends the definition of the class named B.

The code in Listing 7 (p. 1249) declares several instance variables for the class named C, and initializes two of them. The purpose of these variables will become clear later when they are used.

(Note also that class C extends class X, in order to illustrate that the class containment hierarchy is independent of the inheritance hierarchy.)

Constructor for class C

Listing 8 (p. 1249) shows the beginning of the constructor for the class named C.

Whenever an object of the class named C is instantiated, the constructor code shown in Listing 8 (p. 1249) does the following:

- Saves the value of an incoming parameter in a private instance variable named `cVar` .
- Increments the object counter named `objCntC` , which is a class variable of the class named A, maintaining a count of objects instantiated from class C.
- Saves the value of the object counter in an instance variable named `objNumber` to identify the specific object.
- Displays a message showing the identification of the object being instantiated.

Screen output

Listing 1 (p. 1247) shows the instantiation of a new object of class C, immediately following the instantiation of an object of class B.

The object instantiated from the member class named C is linked to the object instantiated from the member class named B. Similarly, the object instantiated from the member class named B is linked to the object instantiated from the top-level class named A.

The constructors for the classes named A, B, and C produce the three lines of output shown in Figure 4 (p. 1244) , the first two of which are repeated from Figures 2 and Figure 3 (p. 1244) .

The output shown in Figure 4 (p. 1244) demonstrates that the code in Listing 1 (p. 1247) causes the constructors for the three classes to be executed in sequence.

At this point, I am going to put the discussion of the class named C on hold and discuss another member class named D.

The private member class named D

Top-level classes cannot be private. However, member classes can be private provided that the using code is consistent with the use of private members. To demonstrate this, the class named C contains a private member class named D, which is shown in its entirety in Listing 9 (p. 1250) .

The most significant thing about the class named D is that it is declared private.

When an object is instantiated from the class named D, it displays a couple of messages, one of which provides the name of the class file produced by the compiler to represent the class named D. We will see those messages shortly in conjunction with the instantiation of an object of the class named D.

Returning to the constructor for class C

Listing 10 (p. 1250) shows the next statement in the constructor for the class named C. This statement instantiates an object of its private member class named D.

The code in Listing 10 (p. 1250) causes the constructor for the class named D to be executed, producing the screen output shown in Figure 5 (p. 1244) .

As mentioned earlier, comparing the class file name in Figure 5 (p. 1244) with the class file naming convention for member classes, you can determine that D is a member of C, C is a member of B, and B is a member of A.

Instantiate independent objects of classes A and B

The remaining constructor code for class C is shown in Listing 11 (p. 1250) .

The code in Listing 11 (p. 1250) instantiates new and independent objects of the classes named A and B, both of which are enclosing classes of the member class named C.

(Note that the parameter values passed to the constructors are different than was the case for the objects instantiated in Listing 1 (p. 1247) . We will see the result of that later.)

I will display information about these two objects later. That information will show that the new object of the member class named B is linked to the original object of the enclosing class named A.

The screen output

In the meantime, when these two objects are instantiated, their constructors are executed, producing the screen output shown in Figure 6 (p. 1244) .

In each case, the value of the object counter shows that this is the second object instantiated from each of these two classes.

Methods aShow, bShow, and cShow

The classes named A, B, and C, each contain display methods named **aShow** , **bShow** , and **cShow** respectively.

The method named **cShow** is rather long, and I will discuss it in detail shortly. For now, suffice it to say that code in **cShow** calls the private method named **bShow** in the containing object to which it is linked. Therefore, this will be an appropriate time to examine the method named **bShow** , which is defined in the member class named B.

The method named bShow

The **bShow** method, defined in the member class named B, is shown in Listing 12 (p. 1250) . It is important to note that this is a private method.

When this method is called, it does the following:

- Displays the value of the constructor parameter passed to the object when it was constructed.
- Displays the identification of the object based on the value of the object counter when it was constructed.
- Calls the corresponding **aShow** method of the object of the containing class to which it is linked.

Since the code in the **bShow** method calls the private **aShow** method of the containing object to which it is linked, it is also time to take a look at that method.

The method named aShow

The **aShow** method, defined in the top-level class named A, is shown in Listing 13 (p. 1251) . It is also important to note that this is a private method.

When this method is called, it does the following:

- Displays the value of the constructor parameter passed to the object when it was constructed.
- Displays the identification of the object based on the value of the object counter when it was constructed.

Containment hierarchy is displayed

Because **cShow** calls **bShow** , which in turn calls **aShow** , we should expect that the call to the **cShow** method on an object of the member class named C would display information about the containment hierarchy.

(Simply as another reminder, the containment hierarchy is completely independent of the inheritance hierarchy.)

Calling cShow

Referring once more to Listing 1 (p. 1247) , we see that the method named **cShow** is called on the object of the class named C when that object is instantiated. We will see the result of that call shortly.

The cShow method

Listing 14 (p. 1251) shows the beginning of the **cShow** method.

The code in Listing 14 (p. 1251)

- Displays a string separator to help locate the specific output in the large quantity of output produced by the program.
- Displays the object identifier based on the object counter.
- Displays the value passed to the constructor when the object was instantiated.

The screen output

The code in Listing 14 (p. 1251) produces the output shown in Figure 7 (p. 1245) .

As you can see by comparing this with Listing 1 (p. 1247) , this is the first object instantiated from the class named C, and is the object instantiated from the statement in the **main** method in Listing 1 (p. 1247) . *(The constructor parameter value is 3.)*

Call the bShow method

Continuing with the code in the **cShow** method, the code in Listing 15 (p. 1251) calls the private method named **bShow** on the containing object of the class B to which this object is linked.

As you will recall from the previous discussion, the code in the **bShow** method will, in turn, call the **aShow** method on the containing object of the class named A to which the object of the class B is linked.

The screen output

The code in Listing 15 (p. 1251) produces the output shown in Figure 8 (p. 1245) .

As you can see in Figure 8 (p. 1245) , the linked objects of the classes B and A are the first objects instantiated from those classes. In addition, the saved values of the constructor parameters show that these are the objects that were instantiated by the statement in the **main** method of Listing 1 (p. 1247) .

Call the **aShow** method

As I explained earlier, the object of the class C is linked to the containing object of the class named B. The code in Listing 16 (p. 1251) shows that the object of the class C is also linked to the containing object of the class A (*even though the containing class named A is one level removed in the containment hierarchy*).

Implicit access

The methods of a member class have implicit access to all members (*including private members*) of all containing classes. Thus, the code in the **cShow** method, belonging to the object of the class named C, can directly call the private **aShow** method of the containing class named A.

The screen output

Therefore, the code in Listing 16 (p. 1251) produces the output shown in Figure 9 (p. 1245) .

You can tell by the values displayed in Figure 9 (p. 1245) that the **aShow** method called in Listing 16 (p. 1251) was called on the same object on which the **aShow** method was called by the code in Listing 15 (p. 1251) . However, in Listing 15 (p. 1251) , the **bShow** method was called first, which in turn called the **aShow** method.

Accessing the object of the class C, and the **this** keyword

The syntax used with the keyword **this** is somewhat different for member classes and contained objects than is the case for top-level classes. For example, continuing with the method named **cShow** , the code in Listing 17 (p. 1252) shows five different ways to access the object instantiated from the member class named C in order to get and display the name of the class file that represents the member class named C.

The screen output

All five statements in Listing 17 (p. 1252) display the name of the same class file, as shown in Figure 10 (p. 1245) .

Obviously in this situation, the last three statements in Listing 17 (p. 1252) are overly complex. There is no particular problem writing code in the method named **cShow** to gain access to the object to which the method belongs. It isn't even necessary to use **this** to refer to that object, although the use of the hidden reference **this** may make the code more readable.

Accessing the containing object of the class B

However, things get a little more complicated when you need to gain access to a containing object, such as the containing object instantiated from the class named B.

The two statements shown in Listing 18 (p. 1252) gain access to the containing object of the class named B. Each statement gets and displays the name of the class file that represents the member class named B. (*Note the use of the keyword **this** in these statements.*)

The screen output

The output produced by the code in Listing 18 (p. 1252) is shown in Figure 11 (p. 1246) . Once again, both statements get and display the name of the same class file.

Accessing the containing object of the class named A

Finally, the code in Listing 19 (p. 1252) gains access to the containing object of the class named A. (*Once again, note the use of the **this** keyword in the statement in Listing 19 (p. 1252) .*)

The code in Listing 19 (p. 1252) produces the output shown in Figure 12 (p. 1246) .

(Since the class named A is a top-level class, the name of the class file is the same as the name of the class, with no \$ characters inserted by the compiler.)

Investigate independent objects of classes A and B

Recall that when the object of the member class named C was instantiated, the constructor for the class instantiated independent objects of the enclosing classes named A and B, and saved those object's references in instance variables of the class named C.

(See Listing 11 (p. 1250) , noting the parameter values of 10 and 20 passed to the constructors for A and B. Recall that the constructors for A and B save those parameter values in private instance variables named **aVar** and **bVar** .)

Display variable values and class file names

The code in Listing 20 (p. 1253) displays the values stored in the private instance variables belonging to those objects. The code in Listing 20 (p. 1253) also displays the names of the class files representing the classes from which those objects were instantiated.

Screen output

The code in Listing 20 (p. 1253) produces the output shown in Figure 13 (p. 1246) .

There should be no surprises in the output shown in Figure 13 (p. 1246) . The values of the instance variables match the parameter values passed to the constructors in Listing 11 (p. 1250) when the objects were instantiated. The class file names match what you already know to be true from previous discussions earlier in this module.

Call the private bShow method

The code in Listing 21 (p. 1253) is somewhat more interesting. This code calls the private **bShow** method on the separate object instantiated from the class named B in order to identify the object to which that object is linked.

The screen output

The output produced by the code in Listing 21 (p. 1253) is shown in Figure 14 (p. 1246) . Even though this object of the member class B was instantiated from within the constructor for the member class named C, the object of the class named B is internally linked to the object of the class named A that was originally used to instantiate the object of the class named C.

(See Listing 1 (p. 1247) where the objects of classes named A, B, and C were originally instantiated. This object of the class named B is a different object from the object of the class named B instantiated in Listing 1 (p. 1247) . This object of the class named B was instantiated by the code in Listing 11 (p. 1250) .)

How is this determined from Figure 14 (p. 1246) ?

The second line in Figure 14 (p. 1246) shows that a parameter value of 20 was received by the constructor when the object of the class named B was instantiated. This corresponds to the instantiation of the object by the code in the constructor in Listing 11 (p. 1250) .

The third line in Figure 14 (p. 1246) shows that this was the second object instantiated from the class named B. (See the definition of the **bShow** method in Listing 12 (p. 1250) , which displays the value stored in a variable that is used to save the object number.)

The proof of the pudding

Now recall that the method named **bShow** (belonging to an object of the class B) calls the method named **aShow** belonging to the object of the class named A to which it is internally linked.

The fourth line in Figure 14 (p. 1246) shows the value of the parameter passed to the constructor for the object of class A when that object was instantiated. (See the definition of the **aShow** method in Listing 13 (p. 1251) .) This value corresponds to the value that was passed to the constructor for the original object of class A when it was constructed in Listing 1 (p. 1247) .

(It does not correspond to the value passed to the constructor for the class named A when the object of the class A was constructed in Listing 11 (p. 1250) .)

The fifth line in Figure 14 (p. 1246) shows that the object was the first object instantiated from the class named A.

Both B objects link to the same A object

Thus, both objects instantiated from the class named B in this program are internally linked to the same object instantiated from the class named A, which is the enclosing class for the class named B.

(However, had I instantiated the new object of the class B using a statement such as the following,

```
new A(100).new B(200).bShow();
```

the new object of the class B would have been linked to the new object of the class A rather than being linked to the original object of the class A. As you can see, keeping mental track of which object is linked to which other object could become complicated.)

Call the aShow method on the other A object

The code in Listing 22 (p. 1253) calls the private **aShow** method on the independent object of the class A that was instantiated in the constructor for class C, shown in Listing 11 (p. 1250) .

The output produced by the code in Listing 22 (p. 1253) is shown in Figure 15 (p. 1247) .

It should come as no surprise that this object of the class A was instantiated with a constructor parameter value of 10, and that it was the second object of the class named A that was constructed.

This is simply a matter of code in the constructor for class C instantiating an object of a top-level class, and is no different in concept from instantiating an object of the member class B, also shown in Listing 11 (p. 1250) .

Inheritance and containment hierarchies are independent

The remaining code is designed to demonstrate that the containment hierarchy is completely independent of the inheritance hierarchy.

The class named C is a member of (*is contained in*) the class named B. That constitutes a part of the containment hierarchy.

The class named C also extends the class named X, which in turn extends the class named **Object** . That constitutes the inheritance hierarchy.

Overridden toString methods

I'm going to put the discussion of the method named **cShow** on hold and return to that discussion shortly.

The class named X inherits, and overrides the **toString** method, as shown in Listing 2 (p. 1247) . When this version of the **toString** method is called, it returns the string "**toString in Class X** " .

The class named C, which extends the class named X, also overrides the **toString** method as shown in Listing 23 (p. 1253) .

When this version of the **toString** method is called, it returns the string "**toString in Class C** " .

We will see the impact of overriding these two methods later.

Illustrate the inheritance hierarchy

Returning to the **cShow** method, the code in Listing 24 (p. 1254) illustrates the inheritance hierarchy to which the class named C belongs by getting and displaying the value stored in the instance variables named **className** belonging to the object instantiated from the class named C.

*(The object contains two instance variables having the name **className** . One of these instance variables was contributed to the object by the superclass named X. The other was contributed to the object by the class named C.)*

Two instance variables named className

The **String** value **X** was stored in one of the instance variables named **className** by the initialization of the variable shown in Listing 2 (p. 1247) .

The **String** value **C** was stored in the other instance variable named **className** by the initialization of the variable shown in Listing 7 (p. 1249) .

*(Note that the variable named **className** is **protected** in the class named X. A subclass method cannot access a private variable in a superclass. To be accessible by a subclass method, the superclass variable must be **protected** , **package-private** , or **public** .)*

Two overridden toString methods

An object instantiated from the class named C also contains two overridden versions of the **toString** method. One version of the method was contributed to the object by the superclass named X. The other version was contributed to the object by the class named C.

Call the toString methods

The code in Listing 24 (p. 1254) also calls the two overridden `toString` methods belonging to the object instantiated from the classes named C. As explained earlier, one version of the `toString` method is overridden in the class named X and the other version is overridden in the class named C.

(Note the use of the `super` keyword to access the variable named `className` and the method named `toString` contributed to the object by the superclass named X.)

The code in Listing 24 (p. 1254) also signals the end of the `cShow` method.

The screen output

The output produced by the code in Listing 24 (p. 1254) is shown in Figure 16 (p. 1247) .

Figure 16 (p. 1247) shows that even though the class named C is contained in the class named B, the superclass of C is X, and is not B. To repeat, the containment hierarchy is **entirely independent** of the inheritance hierarchy.

(Note, however, that there is nothing to prevent you from establishing an inheritance relationship between a member class and one of its containing classes if such a relationship will serve your needs. For example, in this program, it would be technically acceptable for the class named B to extend the class named A provided that either:

- *A noarg constructor is provided for the class named A, or*
- *The constructor for the class named B calls the parameterized constructor belonging to the class named A.)*

And that is probably more than you ever wanted to know about the detailed relationships involving member classes. However, once you start using member classes, you will need to keep these relationships in mind.

4.2.3.5 Run the program

I encourage you to copy the code from Listing 25 (p. 1254) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.2.3.6 Summary

In addition to a number of other items, a class definition can contain:

- Member classes
- Local classes
- Anonymous classes
- Nested top-level classes and interfaces

This module explains member classes. Future modules will explain local classes and anonymous classes

A *member class* is a class that is defined inside the definition of another class without being declared static.

An object of the member class must be internally linked to an object of the enclosing class. A member class is truly an inner class because an object of the member class cannot exist in the absence of an object of the enclosing class.

The methods of a member class have direct access to all the members of the enclosing classes, including private members. Thus the use of member classes can eliminate the requirement to connect objects together via constructor parameters. This is particularly useful in those cases where there is no reason for an object of a member class to exist in the absence of an object of the enclosing class, and where the methods of the object of the member class need access to members of the object of the enclosing class.

The containment hierarchy of member classes is independent of the inheritance hierarchy. However, it is technically possible to establish an inheritance relationship between a member class and one of its enclosing classes.

Member classes may be declared private, and may be instantiated from code that would normally have access to a private member at that level.

4.2.3.7 What's next?

The next module in this series will explain and discuss local classes. A future module will explain *anonymous* classes.

4.2.3.8 Complete program listing

A complete listing of the program discussed in this module is show in Listing 25 (p. 1254) .

4.2.3.9 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java OOP: Member Classes
- File: Java1636.htm
- Published: 11/18/13

Disclaimers: Financial : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

In the past, unknown individuals have copied my modules from cnx.org, converted them to Kindle books, and placed them for sale on Amazon.com showing me as the author. I neither receive compensation for those sales nor do I know who does receive compensation. If you purchase such a book, please be aware that it is a copy of a module that is freely available on cnx.org and that it was made and published without my prior knowledge.

```

Illustrates the use of member classes. Class B is a member class of class A. Class C is a member class of class B. Class D is a private member class of class C. An object is instantiated from the class named A, which makes it possible to instantiate an object of the member class named B. According to Flanagan, this causes the object of the Class B to be internally associated with the object of the class named A. The object of the class named B is used to instantiate an object of the member class named C. This object is internally associated with the object of the class B.

When the object of the class C is instantiated, the constructor for that class instantiates separate objects of the classes named A and B and also instantiates an object of the private member class named D. The new and separate object of the class B continues to be internally associated with the original object of the Class A.

A variety of operations are performed from within methods belonging to the object of the Class C to illustrate the various characteristics of objects instantiated from member classes. Comments in the code explain the purpose of each of those operations.

The compilation of this program produces the following class files:

```
A$B$C$D.class
A$B$C.class
A$B.class
A.class
InnerClasses06.class
X.class
```

The output from this program is shown below:

```
In xstr for A, objCntA = 1
In xstr for B, objCntB = 1
In xstr for C, objCntC = 1
Construct obj of private class D.

4.2.4.2 Preface

This module is one in a collection of modules designed for teaching *ITSE2317 - Java Programming (Intermediate)* at Austin Community College in Austin, TX.

(Editor's note: As you read this module, you will see that it was originally written around 2003. However, despite many improvements in Java since then, most of what was true then is still true in 2013.)

This module makes several references to my website, which is located at <http://www.dickbaldwin.com/toc.htm>⁴⁴.

4.2.4.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

4.2.4.2.1.1 Figures

- Figure 1 (p. 1272) . Class files produced by the program.
- Figure 2 (p. 1273) . Screen output.
- Figure 3 (p. 1273) . Screen output.
- Figure 4 (p. 1273) . Screen output.
- Figure 5 (p. 1273) . Screen output.
- Figure 6 (p. 1274) . Screen output.
- Figure 7 (p. 1274) . Screen output.
- Figure 8 (p. 1274) . Screen output.
- Figure 9 (p. 1275) . Screen output.

4.2.4.2.1.2 Listings

- Listing 1 (p. 1275) . The controlling class named InnerClasses07.
- Listing 2 (p. 1275) . The class named X.
- Listing 3 (p. 1276) . The class named Y.
- Listing 4 (p. 1276) . Beginning of the class named A.
- Listing 5 (p. 1276) . The showA method in class A.
- Listing 6 (p. 1277) . The delay method in class A.
- Listing 7 (p. 1277) . Beginning the meth method in class A.
- Listing 8 (p. 1277) . Set value of blank final variable.
- Listing 9 (p. 1277) . Beginning of class definition for local class B.
- Listing 10 (p. 1279) . Instantiate two objects of local class B.
- Listing 11 (p. 1279) . Call showB on the first object.
- Listing 12 (p. 1279) . Beginning of showB method in local class B.
- Listing 13 (p. 1280) . More code from showB method.
- Listing 14 (p. 1280) . Use of the keyword this.
- Listing 15 (p. 1280) . Illustrate the inheritance hierarchy.
- Listing 16 (p. 1281) . Call showB method on second object.
- Listing 17 (p. 1281) . Complete program listing.

4.2.4.3 Preview

4.2.4.3.1 What can you include in a class definition ?

There are several different kinds of items that can be included in a class definition. As you learned in the earlier modules in this series, the list includes:

- Static variables
- Instance variables
- Static methods
- Instance methods
- Constructors
- Static initializer blocks
- Instance initializers

Can also contain other class definitions

As you learned in the previous module ⁴⁵, a class definition can also contain the following three kinds of *inner classes*:

- Member classes
- Local classes
- Anonymous classes

The previous module explained member classes. This module will explain local classes. The next module will explain anonymous classes.

4.2.4.3.2 What is a local class ?

A *local class* is a class that is defined within a block of Java code. While local classes are probably most frequently defined within methods and constructors, they can also be defined inside static initializer blocks and instance initializers.

⁴⁵<http://cnx.org/content/m44347/latest/?collection=col11441/latest>

As is the case for an object of a member class (*discussed in the previous module* ⁴⁶), an object of a local class must be internally linked to an object of the enclosing class. I will often refer to that object as the containing object, and make comments about the containment hierarchy.

A local class is truly an inner class, because an object of the local class cannot exist in the absence of an object of the enclosing class.

What about a local interface?

Interfaces defined within classes are implicitly static. This means that they are always *top-level*. There is no such thing as a member interface, a local interface, or an anonymous interface.

4.2.4.3.3 Why use local classes ?

Objects instantiated from local classes share many of the characteristics of objects instantiated from member classes. However, in some cases, a local class can be defined closer to its point of use than would be possible with a member class, leading to improved code readability.

Probably the most important benefit of local classes has to do with accessing the members of enclosing classes. Just like with member classes, methods of a local class have direct access to all the members of the enclosing classes, including private members. Thus the use of local classes can sometimes eliminate the requirement to connect objects together via constructor parameters.

(We will also see in the example program in this module that methods of a local class have direct access to protected members of the superclass of the enclosing class.)

Can be particularly useful when ...

A local class can be particularly useful in those cases where

- There is no reason for an object of the local class to exist in the absence of an object of the enclosing class
- There is no reason for an object of the local class to exist outside a method of the enclosing class
- Methods of the object of the local class need access to members of the object of the enclosing class
- Methods of the object of the local class need access to **final** local variables and method parameters belonging to the method in which the local class is defined

This module approaches local classes from a somewhat theoretical viewpoint. The next module will approach local classes from a more practical viewpoint, including a comparison between local classes and anonymous classes.

4.2.4.3.4 Local classes versus member classes

A local class has approximately the same relationship to a member class that a local variable in a method has to an instance variable of the class containing the method.

4.2.4.3.5 The scope of a local class

As is the case with local variables, the name of a local class is visible and usable only within the block of code in which it is defined (*and blocks nested within that block*). Further, the name of the local class is visible and usable only to code following the class definition within that block.

The methods of a local class can use any **final** local variables or method parameters that are visible from the scope in which the local class is defined.

Similar to member classes

As mentioned earlier, local classes have many characteristics in common with member classes. This includes access to private fields and methods in the containing class. The thing that separates local classes

⁴⁶<http://cnx.org/content/m44347/latest/?collection=col11441/latest>

from member classes is the fact that local classes have access to local variables in the scope in which the local class is defined.

A big restriction

There is a big restriction, however, on the ability of methods of the local class to access local variables and method parameters. The methods in a local class can access local variables and method parameters only if they are declared **final**.

What does Flanagan have to say?

According to one of my favorite authors, David Flanagan, author of *Java in a Nutshell*, the methods in a local class don't really have access to local variables and method parameters. Rather, when an object of the local class is instantiated, copies of the **final** local variables and method parameters referred to by the object's methods are stored as instance variables in the object. The methods in the object of the local class really access those hidden instance variables. (*See the later section entitled *Smoke and mirrors*.*)

Thus, the local variables and method parameters accessed by the methods of the local class must be declared **final** to prevent their values from changing after the object is instantiated.

4.2.4.3.6 Restrictions on local classes

As with member classes, local classes cannot contain **static** members.

As with local variables, local classes cannot be declared **public**, **protected**, **private**, or **static**.

A local class cannot have the same name as any of its enclosing classes.

Smoke and mirrors

As I mentioned in the previous module, every class definition in a Java program, including nested top-level classes, member classes, local classes, and anonymous classes, produces a class file when the program is compiled. According to Flanagan,

"The Java Virtual Machine knows nothing about nested top-level classes and interfaces or the various types of inner classes. Therefore, the Java compiler must convert these new types into standard non-nested class files that the Java interpreter can understand. This is done through source code transformations that insert \$ characters into nested class names. These source code transformations may also insert hidden fields, methods, and constructor arguments into the affected classes."

A reference to the containing object

For example, the compiler automatically inserts a private instance variable in the local class to hold a reference to the containing object. It also inserts a hidden argument in all constructors for the local class, and passes the containing object's reference to the constructor for the local class. The modified constructor saves that reference in the private instance variable of the object of the local class. Thus each object instantiated from the local class contains a private reference to the containing object.

Accessing private members

In those cases where it is necessary for an object of the local class to access private members of the containing object, the compiler automatically creates and uses accessor methods that make such access possible.

Similar to your code

The bottom line is that the code that is automatically produced by the compiler is probably very similar to code that you would write if you were writing the program using only top-level classes. The good news is that you don't have to write that extra code, and you don't have to maintain it. The extra code is written for you, and if you modify your class structure, the extra code is automatically modified accordingly.

4.2.4.4 Discussion and sample code

The paragraphs that follow will explain a program named **InnerClasses07**. This program is designed specifically to illustrate various characteristics of local classes. I will discuss the program in fragments. A

complete listing is shown in Listing 17 (p. 1281) near the end of the module.

This program illustrates the use of local classes. The program consists of a total of five classes:

- Four top-level classes named
 - InnerClasses07
 - A
 - X
 - Y
- A local class named B.

When compiled, the program produces the class files shown in Figure 1 (p. 1272) . The file named A\$1\$B.class represents the local class. The remaining files in Figure 1 (p. 1272) represent the four top-level classes.

4.2.4.4.1 Class hierarchy

In the previous module, I explained that once you understand the class file naming convention, you can determine from the file names how top-level classes and member classes are structured. However, the situation isn't nearly so clear when it comes to local classes and anonymous classes. This will become more apparent in the next module, which combines local classes and anonymous classes.

4.2.4.4.2 Overall program structure and behavior

Containment hierarchy

The program named `InnerClasses07` defines a local class named `B` inside an instance method named `meth` .

The method named `meth` is an instance method of a top-level class named `A` . The method named `meth` instantiates two separate objects of the local class named `B` , and calls a method named `showB` on each of them.

The method named `showB` displays certain data values that illustrate the characteristics of local classes, as well as the containment hierarchy among objects of the local class and an object of the containing class.

In this case, objects of the class named `B` are *contained within* an object of the class named `A` .
(*The class named `A` is an enclosing class of the class named `B` .*)

Inheritance hierarchy

The top-level class named `A` extends the top-level class named `X` , (*which in turn, extends `Object`*).

The class named `B` is contained in or enclosed by the top-level class named `A` , but extends the top-level class named `Y` , (*which in turn, extends `Object`*).

There is no inheritance relationship between the classes `X` and `Y` (*aside from their common superclass named `Object`*).

There is no inheritance relationship between the classes `A` and `B` .

The method named `showB` also displays data values that are intended to demonstrate that the inheritance hierarchy is independent of the containment hierarchy.

(Note that while the containment hierarchy of local classes is independent of the inheritance hierarchy, it is technically possible to establish an inheritance relationship between a local class and one of its enclosing classes. For example, by making a couple of minor modifications, it is possible to cause the local class `B` in this program to extend the enclosing class `A` instead of the top-level class `Y` .)

4.2.4.4.2.1 The controlling class

The entire controlling class named `InnerClasses07`, including the `main` method and a static variable named `baseTime`, is shown in Listing 1 (p. 1275).

The static variable named `baseTime` is initialized with the current date and time in milliseconds (*relative to January 1, 1970*). This static variable is used later as a base to establish the relative points in time that certain activities occur during the execution of the program.

The main method

The `main` method shown in Listing 1 (p. 1275) instantiates a new object of the class named `A` and calls the method named `meth` on that object.

This method will sequentially instantiate two separate objects of a local class named `B` that is defined inside the method named `meth`. Then the method named `meth` will call a method named `showB` on each of those objects, causing them to display data values that illustrate the characteristics of local classes.

4.2.4.4.2.2 The class named X

The top-level class named `X` is shown in Listing 2 (p. 1275).

The class named `A` extends this class to illustrate the difference between the inheritance hierarchy and the containment hierarchy. Note that this class defines and initializes a protected instance variable, which will be accessed later to illustrate the inheritance hierarchy.

(Somewhat surprisingly, you will also see later that this protected instance variable belonging to the superclass of the enclosing class `A` is also accessible by methods belonging to an object of the local class via the containment hierarchy.)

4.2.4.4.2.3 The class named Y

The top-level class named `Y` is shown in Listing 3 (p. 1276).

The local class named `B` extends this class to illustrate the difference between the inheritance hierarchy and the containment hierarchy.

Note that this class defines and initializes a protected instance variable. It also overrides the `toString` method, which is inherited from the `Object` class.

The instance variable and the overridden `toString` method will be accessed later to illustrate the inheritance hierarchy.

4.2.4.4.2.4 The class named A

The code in Listing 4 (p. 1276) shows the beginning of the top-level class named `A`.

This code declares and initializes a private instance variable named `aTime`, which establishes the relative time that an object of class `A` is instantiated.

This private instance variable will be accessed directly by code belonging to an object of the local class `B`, which is contained by an object of the class `A`.

Listing 4 (p. 1276) also shows the constructor for class `A`, which displays the time whenever an object is instantiated from class `A`.

The screen output

The code shown earlier in the `main` method of Listing 1 (p. 1275) instantiates an object of class `A`. This causes the screen output shown in Figure 2 (p. 1273).

(Note that the relative time output value on your system may be different, depending on the speed of your system and the impact of other applications that may be running concurrently.)

The private showA method

Listing 5 (p. 1276) shows a private method named `showA`. This method displays the following information about an object instantiated from class `A`:

- The relative time that the object was instantiated.
- The value of the instance variable named `xVar` , which is an instance variable of the superclass of class `A` .
- The name of the class file that represents the class named `A` .

Code in methods belonging to an object of the local class named `B` , contained in an object of class `A` , has direct access to private members of objects of the containing or enclosing class.

The private `showA` method will be called by a method named `showB` , belonging to an object of the local class `B` , to demonstrate the truth of this statement.

The method named `delay`

Listing 6 (p. 1277) shows a utility method named `delay` , which is an instance method of class `A` .

The purpose of the `delay` method is simply to insert a 30-millisecond delay in the execution of the program. This method is used to cause certain activities in the execution of the program to be spread far enough apart in time to make them distinguishable, one from the other, on the basis of relative time.

The method named `meth`

The method named `meth` is an instance method of the class `A` . The beginning of this method is shown in Listing 7 (p. 1277) .

The method named `meth` contains a local class definition for a class named `B` , which we will examine later.

As you can see in Listing 7 (p. 1277) , it also declares a `final` local variable named `methTime` . As you will see later, the method named `meth` instantiates two separate objects of local class `B` and calls a method named `showB` on each of those objects.

The method named `showB` displays various data values that illustrate the characteristics of local classes, including the value of the `final` local variable named `methTime` .

Access to final local variables

One of the characteristics of a local class is that objects of a local class have access to local variables within the same scope, provided that those local variables are declared `final` .

Blank final variables

The code in Listing 7 (p. 1277) declares a `final` local variable named `methTime` . Because of the syntax used, this variable is known as a *blank final* variable. A blank final variable is not initialized when it is declared.

As with all local variables, the variable cannot be used until a value has been assigned to it. Because this variable is declared `final` , once a value has been assigned to it, the value cannot be changed throughout the remaining life of the variable.

Set value of blank final variable

The code in Listing 8 (p. 1277)

- Inserts a delay
- Sets a value for the `final` local variable named `methTime`
- Displays the value that was set in `methTime`
- Inserts an additional delay before continuing

The value that is set in the variable named `methTime` is the relative time that the statement is executed.

The screen output

The code in the `main` method of Listing 1 (p. 1275) calls `meth` on a new object of class `A` , producing the screen output shown in Figure 3 (p. 1273) .

(Once again, the actual time value displayed by your system may be different, depending on the speed of your system and other factors as well.)

4.2.4.4.2.5 The local class named **B**

The next block of code in the method named **meth** is the definition of a local class named **B** . The beginning of the class definition for local class **B** is shown in Listing 9 (p. 1277) .

As with local variables, the class definition for a local class must appear before the code that attempts to instantiate the class. Code in the method named **meth** following the local class definition will instantiate and exercise objects of class **B** .

Local class **B** extends top-level class **Y** . This was done to illustrate that the inheritance hierarchy is independent of the containment hierarchy.

The constructor

The code in Listing 9 (p. 1277) declares a private instance variable named **bTime** , which is used to store the relative time that an object of class **B** is constructed.

Listing 9 (p. 1277) also shows the constructor for local class **B** , which establishes, saves, and then displays the relative time that that an object is instantiated.

(I will show you the screen output produced by this constructor shortly as I discuss code that instantiates objects of this class.)

Instantiate two objects of class **B**

At this point, I am going to temporarily set aside the discussion of local class **B** and discuss code in the method named **meth** that immediately follows the definition of local class **B** . This code is shown in Listing 10 (p. 1279) .

Listing 10 (p. 1279) shows the beginning of code that is called when the method named **meth** is called. This code begins by instantiating two objects from the class named **B** , with a delay inserted between the instantiation of the two objects.

The screen output

The code in Listing 10 (p. 1279) , in conjunction with the constructor code in Listing 9 (p. 1277) produces the screen output shown in Figure 4 (p. 1273) as each of the two objects of local class **B** are instantiated.

Call **showB** on the first object

Following this, the code in the method named **meth** calls the method named **showB** on each of the two objects. The method named **showB** will, in turn, call the method named **showA** on the containing object instantiated from the class named **A** . The third line of code in Listing 11 (p. 1279) calls the method named **showB** on the first object instantiated in Listing 10 (p. 1279) .

The method named **showB**

That brings us back to a discussion of the method named **showB** , which is an instance method of local class **B** . The beginning of the **showB** method is shown in Listing 12 (p. 1279) . This method displays several private and protected variables, some of which belong to the containing object instantiated from the top-level class named **A** .

*(Note that code in this method has direct access to **xVar** , which is a protected member variable of the superclass of the class named **A** .)*

Items that are displayed

The code in Listing 12 (p. 1279) displays

- A visual line separator, -1-
- A private instance variable, **bTime** , belonging to the object instantiated from local class **B**
- A private instance variable, **aTime** , belonging to the containing object instantiated from the top-level class **A**
- A **final** local variable, **methTime** , belonging to the method named **meth** , in which the local class **B** is defined
- A protected instance variable, **xVar** , of the superclass of the class **A** , from which the containing object was instantiated.

- A protected instance variable, `yVar`, of the superclass of the local class `B`
- The name of the class file that represents the local class `B`

The screen output

The combined code in Listing 11 (p. 1279) and Listing 12 (p. 1279) produces the output shown in Figure 5 (p. 1273) for the first object instantiated from local class `B`.

Call private method `showA`

One of the important characteristics of local classes is that the methods of objects instantiated from local classes have direct access to all of the members, including private members, of all the containing classes in the containment hierarchy.

(In this case, an object of the local class `B` has only one containing class, an object instantiated from the top-level class `A`.)

Continuing with the method named `showB`, in local class `B`, the code in Listing 13 (p. 1280) displays a line separator, `-2-`, and then calls the private method named `showA` on the containing object. This illustrates the containment hierarchy.

The screen output

The method named `showA` is shown in Listing 5 (p. 1276). The combination of the code in Listing 13 (p. 1280) and Listing 5 (p. 1276) produces the screen output shown in Figure 6 (p. 1274).

Figure 6 (p. 1274) displays

- The relative time that the containing object of the class `A` was instantiated
- A protected instance variable in the superclass of the class from which the containing object was instantiated
- The name of the class file that represents the top-level class named `A`

Use of the keyword `this`

As is the case with member classes, *(discussed in the previous module)*, objects of local classes use a special syntax of the keyword `this` to gain access to objects in the containment hierarchy.

The code in Listing 14 (p. 1280) shows how to use regular syntax to gain access to the current object, and how to use special syntax to gain access to the containing object.

Having gained access to the two objects, the code in Listing 14 (p. 1280) gets and displays the values of private instance variables belonging to those objects.

The screen output

The code in Listing 14 (p. 1280) produced the screen output shown in Figure 7 (p. 1274).

You saw these same two values displayed earlier in Figure 4 (p. 1273) and Figure 2 (p. 1273).

Illustrate the inheritance hierarchy

Remember that the inheritance hierarchy is independent of the containment hierarchy. The code in Listing 15 (p. 1280) illustrates the inheritance hierarchy by

- Calling the overridden `toString` method belonging to the local class `B`
- Using the `super` keyword to call the overridden `toString` method belonging to the class `Y`, which is the superclass of the local class `B`

Listing 15 (p. 1280) also defines the overridden `toString` method belonging to local class `B`. The overridden `toString` method belonging to class `Y` is shown in Listing 3 (p. 1276).

The screen output

The combined code in Listing 15 (p. 1280) and Listing 3 (p. 1276) produces the screen output shown in Figure 8 (p. 1274). *(Once again, you have seen these same values displayed in earlier Figures.)*

That concludes the results of calling the `showB` method on the first object instantiated from local class `B`.

Call `showB` method on second object

The code in Listing 10 (p. 1279) instantiated two objects from local class **B** , and saved the object's references in instance variables named **obj1** and **obj2** . The screen output that I have been discussing resulted from calling the **showB** method on **obj1** in Listing 11 (p. 1279) .

Listing 16 (p. 1281) calls the **showB** method on **obj2** . Listing 16 (p. 1281) also signals the end of the method named **meth** , and the end of the class named **A** .

The screen output The code in Listing 16 (p. 1281) produces the screen output shown in Figure 9 (p. 1275)

Important considerations The important things to note about the output shown in Listing 16 (p. 1281) include:

- The second object instantiated from local class **B** is definitely a different object from the first object instantiated from local class **B** , as evidenced by a different value for **bTime** . (*Compare the value of **bTime** in Figure 9 (p. 1275) with the value of **bTime** in Figure 5 (p. 1273) .*) In other words, the second object was instantiated after the first object was instantiated.
- Even though the two objects instantiated from local class **B** are different objects, they both belong to the same containing object, as evidenced by the same values for **aTime** in Figure 9 (p. 1275) and Figure 5 (p. 1273) .
- The two objects instantiated from local class **B** each access the same **final** local variable belonging to the method named **meth** , as evidenced by the same values for **methTime** in Figure 9 (p. 1275) and Figure 5 (p. 1273) .

4.2.4.5 Run the program

I encourage you to copy the code from Listing 17 (p. 1281) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.2.4.6 Summary

In addition to a number of other items, a class definition can contain:

- Member classes
- Local classes
- Anonymous classes
- Nested top-level classes and interfaces

Member classes were explained in the previous module. This module explains local classes. The next module will explain anonymous classes.

A *local class* is a class that is defined within a block of Java code. While local classes are probably most frequently defined within method and constructors, they can also be defined inside static initializer blocks and instance initializers.

An object of the local class must be internally linked to an object of the enclosing class (*which I often refer to as the containing object*). A local class is truly an inner class because an object of the local class cannot exist in the absence of an object of the enclosing class.

The methods of a local class have direct access to all the members in the hierarchy of enclosing classes, including private members. In addition, the methods of local classes have access to **final** local variables and **final** method parameters in the scope in which the local class is defined.

The containment hierarchy of local classes is independent of the inheritance hierarchy. However, it is technically possible to establish an inheritance relationship between a local class and one of its enclosing classes.

Local classes may not be declared **public** , **protected** , **private** , or **static** .

Local classes cannot contain **static** members.

A local class has approximately the same relationship to a member class that a local variable in a method has to an instance variable of the class containing the method.

4.2.4.7 What's next?

The next module in this series will explain and discuss anonymous classes, and will also compare anonymous classes to local classes.

4.2.4.8 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java OOP: Local Classes

/*File InnerClasses07.java
Copyright 2003 R.G.Baldwin

```

Illustrates the use of local classes.

This program defines a local class named B inside an instance method named meth. The method named meth is an instance method of a class named A.

The method named meth instantiates two separate objects of the local class named B, and calls on each of them a method named showB, which displays certain data values that illustrate the characteristics of local classes, as well as the relationships among objects of a local class and an object to which that object is internally associated. In this case, objects of the class named B are internally associated with an object of the class named A.

This program produces the following class files when compiled:

```

A$1$B.class
A.class
InnerClasses07.class
X.class
Y.class

```

The file named A\$1\$B.class represents the local class named B.

This program produces the following output:

```

In xstr for A, aTime = 10

```

```

In meth, methTime = 40
-----
Instantiate first B-object
In xstr for B, bTime = 70
Delay and instantiate second B-object
In xstr for B, bTime = 100
-----
Display first B-Object

- Listings (p. 1302)

4.2.5.2 Preface

This module is one in a collection of modules designed for teaching *ITSE2317 - Java Programming (Intermediate)* at Austin Community College in Austin, TX.

(Editor's note: As you read this module, you will see that it was originally written around 2003. However, despite many improvements in Java since then, most of what was true then is still true in 2013.)

This module makes several references to my website, which is located at <http://www.dickbaldwin.com/toc.htm>⁵⁰.

4.2.5.2.1 Purpose of this module

This module explains anonymous classes from a practical viewpoint, including a comparison between anonymous classes and local classes.

4.2.5.2.2 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

4.2.5.2.2.1 Figures

- Figure 1 (p. 1301) . Syntax for anonymous classes.
- Figure 2 (p. 1301) . Program GUI.
- Figure 3 (p. 1301) . Class file names.
- Figure 4 (p. 1301) . Screen output.
- Figure 5 (p. 1302) . Screen output.
- Figure 6 (p. 1302) . Screen output.
- Figure 7 (p. 1302) . Screen output.
- Figure 8 (p. 1302) . Screen output.
- Figure 9 (p. 1302) . Screen output.

⁵⁰<http://www.dickbaldwin.com/toc.htm>

4.2.5.2.2 Listings

- Listing 1 (p. 1303) . The controlling class.
- Listing 2 (p. 1303) . Beginning of the GUI class.
- Listing 3 (p. 1303) . Beginning of the BaldButton class.
- Listing 4 (p. 1304) . The processMouseEvent method.
- Listing 5 (p. 1304) . Beginning of anonymous inner class.
- Listing 6 (p. 1305) . Overridden processMouseEvent method.
- Listing 7 (p. 1305) . Register a MouseListener object.
- Listing 8 (p. 1306) . Implementing the interface.
- Listing 9 (p. 1306) . Registering a WindowListener on the Frame .
- Listing 10 (p. 1306) . Complete program listing.

4.2.5.3 Preview

4.2.5.3.1 What can you include in a class definition ?

There are several different kinds of items that can be included in a class definition. As you learned in the earlier modules in this series, the list includes:

- Static variables
- Instance variables
- Static methods
- Instance methods
- Constructors
- Static initializer blocks
- Instance initializers

Can also contain other class definitions

As you also learned in previous modules, a class definition can also contain the following kinds of *inner classes*:

- Member classes
- Local classes
- Anonymous classes
- Nested top-level classes and interfaces

The previous two modules explained member classes and local classes. This module will explain anonymous classes.

4.2.5.3.2 What is an anonymous class ?

I'm going to begin my discussion with a quotation from one of my favorite authors, David Flanagan, author of *Java in a Nutshell* .

"An anonymous class is essentially a local class without a name."

If you have read the previous module, you should know quite a lot about local classes at this point in time. Continuing with Flanagan's words,

*"Instead of defining a local class and then instantiating it, you can often use an anonymous class to combine these two steps... an anonymous class is defined by a Java **expression** , not a Java **statement** . This means that an anonymous class definition can be included within a larger Java expression..."*

As you will see from the sample program in this module, anonymous class definitions are often included as arguments to method calls.

As is the case for an object of a member class or a local class (*discussed in previous modules*), an object of an anonymous class must be internally linked to an object of the enclosing class.

Thus, an anonymous class is truly an inner class, because an object of the anonymous class cannot exist in the absence of an object of the enclosing class.

4.2.5.3.3 What about an anonymous interface ?

Interfaces defined within classes are implicitly static. This means that they are always *top-level*. There is no such thing as a member interface, a local interface, or an anonymous interface.

4.2.5.3.4 Why use anonymous classes ?

As with local classes, objects instantiated from anonymous classes share many of the characteristics of objects instantiated from member classes. However, in some cases, an anonymous class can be defined closer to its point of use than would be possible with a member class or a local class. Once you become accustomed to the somewhat cryptic syntax used with anonymous classes, this can often lead to improved code readability.

Probably the most important benefit of anonymous classes has to do with accessing the members of enclosing classes. Just like with member classes and local classes, methods of an anonymous class have direct access to all the members of the enclosing classes, including private members. Thus the use of anonymous classes can often eliminate the requirement to connect objects together via constructor parameters.

In addition, although not demonstrated in this module, as with local classes, objects of anonymous classes have access to **final** local variables that are declared within the scope of the anonymous class.

Can be particularly useful when ...

An anonymous class can be particularly useful in those cases where

- There is no reason for an object of the anonymous class to exist in the absence of an object of the enclosing class.
- There is no reason for an object of the anonymous class to exist outside a method of the enclosing class.
- Methods of the object of the anonymous class need access to members of the object of the enclosing class.
- Methods of the object of the anonymous class need access to **final** local variables and method parameters belonging to the method in which the anonymous class is defined.
- Only one instance of the anonymous class is needed.
- There is no need for the class to have a name that is accessible elsewhere in the program.

4.2.5.3.5 Anonymous classes versus local classes

Once again, according to David Flanagan,

"...an anonymous class behaves just like a local class, and is distinguished from a local class merely in the syntax used to define and instantiate it."

Unlike a local class, however, an anonymous class cannot define a constructor. However, an anonymous class can define an instance initializer, which can provide some of the benefits of a constructor.

*(I discussed instance initializers in detail in an earlier tutorial titled *The Essence of OOP using Java, Instance Initializers*⁵¹. As you may recall, a primary shortcoming of an instance initializer as compared to a constructor is that an instance initializer cannot accept incoming parameters.)*

⁵¹<http://cnx.org/content/m45597/latest/Java1634.htm>

4.2.5.3.6 Restrictions on the use of anonymous classes

Because an anonymous class has no name, and the definition and instantiation of the class appear in a single expression, only one instance of each anonymous class can be created. If you need more than one instance of the class, you should probably use a local class, a member class, or a top-level class instead.

As mentioned above, it is not possible to define constructors for anonymous classes. If you need to use a constructor when you instantiate the class, you should probably use a local class, a member class, or a top-level class instead.

As with member classes and local classes, anonymous classes cannot contain **static** members.

As with local variables and local classes, anonymous classes cannot be declared **public** , **protected** , **private** , or **static** . In fact, no modifiers can be specified in the definition of an anonymous class.

4.2.5.3.7 Smoke and mirrors

As I told you in my earlier modules on local classes, the methods in an anonymous class don't really have access to local variables and method parameters. Rather, when an object of the anonymous class is instantiated, copies of the **final** local variables and method parameters referred to by the object's methods are stored as instance variables in the object. The methods in the object of the anonymous class really access those hidden instance variables.

Thus, the local variables and method parameters accessed by the methods of the local class must be declared **final** to prevent their values from changing after the object is instantiated.

There are some additional activities involving *smoke and mirrors* taking place behind the scenes when you define and instantiate an anonymous class. Generally speaking, this involves the automatic generation of code to cause things to behave as they do. The good news is that you don't have to write that extra code, and you don't have to maintain it. The extra code is written for you, and if you modify your class structure, the extra code is automatically modified accordingly.

You can read about the code that is automatically generated in my earlier modules on local classes and member classes.

4.2.5.3.8 Syntax for anonymous classes

Before getting into actual code in the sample program, I want to explain the syntax used to define and instantiate an anonymous class.

The definition and instantiation of an anonymous class uses one or the other of the two expressions shown in Figure 1 (p. 1301) .

Usually, this expression is included inside a larger overall expression, such as an argument to a method call.

What does the first expression mean?

Here is how I usually explain this syntax to my students. The first expression in Figure 1 (p. 1301) starts out fairly normal, but becomes cryptic very quickly.

This expression instantiates a new object from an unnamed and previously undefined class. That class automatically *extends* the class named **className** , and cannot explicitly implement any interfaces.

The body of the new class is given by **classBody** .

The result of executing this expression is that:

- a new class that extends **className** is defined,
- a new object of the new class is instantiated, and
- the expression is replaced by a reference to the new object.

Example usage

If this expression appears as the right operand of an assignment operator, the new object's reference is saved in the left operand of the assignment operator.

If the expression appears as an argument in a method call, the new object's reference is passed to the method.

If the expression appears in some other form of larger overall expression, the new object's reference is handed over to the surrounding expression to be used appropriately.

What about instantiating an interface?

The second expression in Figure 1 (p. 1301) starts out very weird. To my knowledge, there is no other situation in Java where you apply the `new` operator to the name of an interface.

From the beginning, you have been told (*or should have been told*) that you cannot instantiate an object of an interface. (*An interface is implicitly abstract and it doesn't have a constructor, not even a default constructor.*)

However, you can instantiate an object of a class that implements none, one, or more interfaces.

The correct interpretation of the second expression in Figure 1 (p. 1301) is as follows. This expression instantiates a new object from an unnamed and previously undefined class. That class automatically *implements* the interface named `interfaceName`, and it automatically *extends* the class named `Object`.

The class can explicitly implement one, and only one interface, and cannot extend any class other than `Object`.

Once again, the body of the new class is given by `classBody`.

As in the case of the first expression in Figure 1 (p. 1301), the result of executing this second expression is that

- a new class that implements `interfaceName` is defined,
- a new object of the new class is instantiated, and
- the expression is replaced by a reference to the new object.

That reference is handed over to the surrounding expression to be used appropriately.

What about constructor parameters?

As mentioned earlier in this module, since the new class doesn't have a name, it isn't possible to define a constructor for the new class.

According to Flanagan (*with regard to the first expression in Figure 1 (p. 1301)*),

"Any arguments you specify between the parentheses following the superclass name in an anonymous class definition are implicitly passed to the superclass constructor."

Thus, it is possible to define an anonymous class that extends a class whose constructor requires parameters, and to pass those parameters to the superclass constructor when the anonymous class is instantiated.

The parentheses following `interfaceName` in the second expression in Figure 1 (p. 1301) must always be empty. In this case, the superclass is always `Object`, which never expects constructor parameters.

4.2.5.4 Discussion and sample code

The paragraphs that follow will explain a program named `InnerClasses08`. This program is designed specifically to illustrate anonymous classes, and to compare anonymous classes with local classes.

I will discuss the program in fragments. A complete listing of the program is provided in Listing 10 (p. 1306).

When the program is executed, it produces the GUI shown in Figure 2 (p. 1301). I will refer back to this image during the discussion of the program.

4.2.5.4.1 Class file names

This program consists of a total of six classes:

- Two top-level classes

- InnerClasses08.class
- GUI.class
- One local class
 - GUI\$1\$BaldButton.class
- Three anonymous classes
 - GUI\$1.class
 - GUI\$2.class
 - GUI\$3.class

When compiled, the program produces the class files shown in Figure 3 (p. 1301) .

(As you can see, the anonymous classes are not truly anonymous, since the files that represent them must have names. Generally, however, the establishment of the individual names is beyond the control of the programmer, and the names are not known to the program in a way that makes it possible to refer to them by name.)

4.2.5.4.2 Program structure and behavior

This program is designed to illustrate the use of local classes and anonymous classes in a very practical way. It illustrates one implementation of a local class and three different implementations of anonymous classes. The program compares the local class with an anonymous class designed to accomplish the same purpose. The program also illustrates the use of instance initializers as an alternative to constructors.

4.2.5.4.2.1 A local class

The program defines and uses a local class to instantiate an object to handle *mouse clicked* events on a button with *low-level* event handling. This class uses a constructor to enable mouse events on a new extended **Button** class. It also uses a constructor to display the name of the class file.

4.2.5.4.2.2 Three anonymous classes

An anonymous class to compare with the local class

The program also defines and uses an anonymous class to instantiate an object to handle *mouse clicked* events on a button with *low-level* event handling.

This class uses an instance initializer to enable mouse events on a new extended **Button** class. It also uses an instance initializer to display the name of the class file.

This class and the local class described above provide a direct comparison between the use of local classes and anonymous classes to serve the same purpose.

An anonymous class that implements an interface

The program illustrates the use of an anonymous class that implements the **MouseListener** interface, to instantiate an object to handle mouse clicked events using the source-listener event model (*sometimes referred to as the delegation event model or the JavaBeans event model*). The anonymous class uses an instance initializer to display the name of the class file.

An anonymous class that extends an existing class

The program illustrates the use of an anonymous class that extends the **WindowAdapter** class, to instantiate an object to handle window events fired by the close button in the upper-right corner of the **Frame** object shown in Figure 2 (p. 1301) . This class also uses the source-listener event model, and uses an instance initializer to display the name of the class file.

4.2.5.4.2.3 The screen output

The program produces the screen output shown in Figure 4 (p. 1301) when

- The program is started
- Each button shown in Figure 2 (p. 1301) is clicked once in succession, going from left to right
- The close button in the upper-right corner of the **Frame** object in Figure 2 (p. 1301) is clicked

When the close button is clicked, the program produces the last line of text in Figure 4 (p. 1301) and terminates. I will identify the code that produces each line of output text in the discussion of the program that follows.

4.2.5.4.2.4 The controlling class

The controlling class for the program is shown in Listing 1 (p. 1303) .

As you can see, the controlling class is very simple, with the **main** method instantiating an object of the **GUI** class. This results in the GUI that is pictured in Figure 2 (p. 1301) .

4.2.5.4.2.5 Local and anonymous classes inside GUI constructor

The local class and the three anonymous classes are defined inside the constructor for the **GUI** class.

(Recall that local classes and anonymous classes are defined inside code blocks, which often place them inside methods and constructors, but you can also place them inside static initializer blocks and instance initializers.)

The first four lines of the output text in Figure 4 (p. 1301) are produced by constructors and instance initializers in the local and anonymous classes. Therefore, those four lines of text are produced when the new object of the **GUI** class is instantiated.

4.2.5.4.2.6 The GUI class

As is often the case, the **GUI** class used to create the visual GUI shown in Figure 2 (p. 1301) consists solely of a constructor. Basically, this constructor

- places three buttons in the frame and
- registers event handlers on the buttons and on the frame.

Once the **GUI** object is constructed and appears on the screen, all further activity in the program occurs under control of the event handlers associated with the buttons and the frame.

(You can learn more about event handling here ⁵² .)

The GUI constructor

The **GUI** class, and the constructor for that class begin in Listing 2 (p. 1303) .

As you can see, the **GUI** class extends **Frame** , so that an object of the class is a frame.

The constructor code shown in Listing 2 (p. 1303) simply sets values for the *layout*, *size*, and *title* properties of the frame.

The BaldButton class

The definition of the **BaldButton** class begins in Listing 3 (p. 1303) . This is a local class that extends **Button** .

Extending the **Button** class makes it possible to override the **processMouseEvent** method in order to handle mouse events that are fired by the button.

⁵²<http://cnx.org/content/m47842/latest/?collection=col11441/latest>

This is a form of low-level event handling that will be contrasted with source-listener event handling later in the program.

Listing 3 (p. 1303) shows the constructor for the **BaldButton** class.

Enable mouse events

The most important code in the constructor is the statement that enables mouse events on the button.

If you are unfamiliar with the **enableEvents** method, you should look it up in the Sun documentation. Briefly, this method must be called on the button to cause the overridden **processMouseEvent** method to be called later when the button fires a mouse event.

The remaining constructor code

The remaining code in the constructor

- Sets the text value on the face of the button
- Gets and displays the name of the class file that represents this local class

The screen output

Construction of the button by the code in Listing 3 (p. 1303) causes the text shown in Figure 5 (p. 1302) to appear on the screen. This is how I was able to identify the name of the class file that represents the local class in my earlier discussion of class file names.

We will see later that this button will be added as the leftmost button in the GUI shown in Figure 2 (p. 1301) .

The processMouseEvent method

Continuing with the constructor for the **GUI** class, Listing 4 (p. 1304) shows the overridden **processMouseEvent** method for an object of the **BaldButton** class.

This method is called each time an object instantiated from this class fires a mouse event. That is why I refer to the method as an event handler for the button.

Different kinds of mouse events A button can fire a variety of different kinds or subcategories of **mouse events** :

- **MOUSE_CLICKED**
- **MOUSE_DRAGGED**
- **MOUSE_ENTERED**
- **MOUSE_EXITED**
- **MOUSE_MOVED**
- **MOUSE_PRESSED**
- **MOUSE_RELEASED**

In this case, I elected to ignore all but **MOUSE_CLICKED** . This subcategory of mouse event occurs when a mouse button is pressed and then released.

The code in the event handler of Listing 4 (p. 1304) first confirms that the event was of the **MOUSE_CLICKED** variety. If so, it displays a message that matches the fifth line of text in the output shown in Figure 4 (p. 1301) .

Call processMouseEvent on the superclass

Without getting into the details of why this is required, I'm simply going to tell you that when you use this low-level event model to handle events, your overridden **processMouseEvent** method must call the same method in the superclass, passing the incoming parameter of type **MouseEvent** as a parameter to the superclass version of the method.

Add a button to the frame

The last statement in Listing 4 (p. 1304) instantiates a new **BaldButton** object, setting the text on the face of the button to **A** , and adds that new object to the frame.

Because the layout property of the frame has been set to **FlowLayout** ⁵³ , and because this is the first component added to the frame, this button appears as the leftmost button in the GUI shown in Figure 2 (p. 1301) .

⁵³<http://cnx.org/content/m45597/latest/Java116.htm>

Could instantiate multiple buttons of this type

Although I instantiated the button object as an anonymous object in this case, that wasn't necessary. Using this local class, I could instantiate more than one object of this type, saving the object's references in reference variables of the appropriate type. Later we will see that this is not possible for anonymous classes.

It is interesting to note, however, that with this event handling model, if I were to instantiate multiple buttons of this type, the same `processMouseEvent` method would be called no matter which of the buttons fired a mouse event. If I wanted different behavior as a result of the different buttons firing mouse events, I would have to write code inside the `processMouseEvent` method to deal with that issue.

The source-listener event model that I will illustrate later doesn't suffer from that restriction.

4.2.5.4.2.7 An anonymous inner class for low-level event handling

Listing 5 (p. 1304) shows the beginning of an anonymous class to perform low-level event handling similar to that shown in Listing 4 (p. 1304) .

This code defines an anonymous inner class that implicitly extends `Button` and has mouse events enabled. I provided this class primarily for comparison with the local class named `BaldButton` . This class is an anonymous alternative to the local `BaldButton` class.

An argument to the add method

Note that the definition of this anonymous class appears as an argument to the `add` method for the frame. Thus, the anonymous object instantiated from the anonymous class is added as the second (*middle*) button in Figure 2 (p. 1301) .

Extends the Button class

Note also that this form of anonymous class implicitly extends the `Button` class. Once again, this makes it possible to override the `processMouseEvent` method belonging to the `Button` class.

An instance initializer

As I mentioned earlier in this module, it is not possible to define a constructor for an anonymous class. However, it is possible to define an instance initializer.

(In Listing 5 (p. 1304) , the instance initializer consists of two statements enclosed by matching curly brackets.)

This class defines an instance initializer that

- Enables mouse events on an anonymous object instantiated from the anonymous class.
- Gets and displays the name of the class file that represents the anonymous class.

The screen output

Therefore, the instantiation of this anonymous object causes the text shown in Figure 6 (p. 1302) to appear on the screen. About all you can tell by looking at this class name is that it is the name of a file that represents an anonymous class.

Overridden processMouseEvent method

The remaining code in the anonymous class definition is shown in Listing 6 (p. 1305) . The code in Listing 6 (p. 1305) consists of

- an overridden `processMouseEvent` method, plus
- the curly brackets, parentheses, and semicolon necessary to complete the expression and the statement.

Same code as before

The code in this overridden `processMouseEvent` method is essentially the same as that shown for the local class in Listing 4 (p. 1304) , except that it produces a different message on the screen when the user clicks the button.

Clicking the middle button in Figure 2 (p. 1301) produces the screen output shown by the sixth line in Figure 4 (p. 1301) .

4.2.5.4.2.8 Instantiating and registering a `MouseListener` object

Implementing a listener interface

Now I'm going to switch from *low-level* event handling to *source-listener* event handling. The code to accomplish this begins in Listing 7 (p. 1305) .

With this event handling model:

- A listener object is instantiated from a class that implements a specific listener interface. In this case, that interface will be the `MouseListener` interface.
- The listener object is *registered* on an object that knows how to fire events of a type that is associated with the listener interface. In this case, that will be events of type `MouseEvent` .
- When the source object fires an event of the specified type, one of the methods belonging to the registered listener object will be called to handle the event. The different methods belonging to the listener object are declared in the implemented listener interface.

Listing 7 (p. 1305) begins by instantiating a new `Button` object.

(Note that with this event model, it is not necessary to extend the `Button` class, because it is not necessary to override methods belonging to the `Button` object.)

Register a `MouseListener` object

After instantiating the `Button` object, the code in Listing 7 (p. 1305) calls the `addMouseListener` method to register a `MouseListener` object on that button. The argument to the `addMouseListener` method must be a reference to an object instantiated from a class that implements the `MouseListener` interface.

Instantiate the listener object

In this case, that listener object is created by

- writing an expression to instantiate an anonymous object from an anonymous class and
- placing that expression as an argument to the `addMouseListener` method.

Implement the `MouseListener` interface

The definition of the anonymous class in this example uses the syntax that implements an interface.

An instance initializer

As before, an instance initializer is used to get and display the name of the class file that represents the anonymous class. Thus, when the new anonymous object of the anonymous class is instantiated, the text shown in Figure 7 (p. 1302) appears on the screen.

Note the similarity of this class file name to that shown earlier in Figure 6 (p. 1302) . *(You can also compare them in Figure 4 (p. 1301) .)* The names of the two class files differ only with respect to a number that is provided by the compiler to guarantee that each class file name is unique.

Implementing the interface

Whenever a class implements an interface, it must provide a concrete definition for each of the methods declared in the interface, even if some of those methods are empty.

Continuing with the definition of the anonymous class, Listing 8 (p. 1306) provides definitions for all five of the methods declared in the `MouseListener` interface. Four of those methods are defined as empty methods.

Separation of event subcategories

One of the major differences between the *low-level* event model discussed earlier and the *source-listener* model being discussed here has to do with where the separation between the different subcategories (*mouseClicked*, *mousePressed*, *mouseReleased*, etc.) of a given event type is accomplished.

In the low-level model, the separation must be accomplished by code in the overridden event handler method, such as with the `if` statement in the `processMouseEvent` method defined in Listing 6 (p. 1305) .

In the source-listener model, the separation is accomplished before the event handler method is called, and a specific event handler method, such as the `mouseClicked` method is called on the listener object.

When the button fires a mouse event ...

In this case, whenever the button fires a `MouseEvent` of the `MOUSE_CLICKED` subcategory (p. 1295), the `mouseClicked` method defined in Listing 8 (p. 1306) will be called automatically, causing the seventh line of text in Figure 4 (p. 1301) to appear on the screen.

Whenever the button fires a `MouseEvent` of one of the other subcategories (p. 1295), one of the empty methods defined in Listing 8 (p. 1306) will be called. This method will return immediately, doing nothing but wasting a little computer time.

(In case you are wondering what happened to the `mouseMoved` and `mouseDragged` methods, they are defined in the `MouseMotionListener` interface instead of the `MouseListener` interface.)

Add the button to the frame

Finally, the last statement in Listing 8 (p. 1306) adds the new button to the `Frame` as the rightmost button in Figure 2 (p. 1301).

A disclaimer

I wrote this code the way that I did in Listing 8 (p. 1306) to illustrate an anonymous class that implements an interface. In real life, I would probably cause the anonymous class to extend the `MouseAdapter` class and override the `mouseClicked` method instead of implementing the `MouseListener` interface. That would eliminate the requirement for me to define the four empty methods in Listing 8 (p. 1306).

4.2.5.4.2.9 Extending the WindowAdapter class

The above disclaimer provides a perfect lead-in to the definition of the anonymous class shown in Listing 9 (p. 1306).

Registering a WindowListener on the Frame

The code in Listing 9 (p. 1306) instantiates an anonymous object of an anonymous class that extends the `WindowAdapter` class.

That anonymous object is registered as a `WindowListener` on the `Frame` by passing the object's reference to the `addWindowListener` method belonging to the `Frame`.

(The `addWindowListener` method requires an incoming parameter of type `WindowListener`. This is satisfied by the fact that the `WindowAdapter` class implements the `WindowListener` interface. Thus, an object instantiated from a class that extends `WindowAdapter` can also be treated as type `WindowListener`.)

The screen output

This anonymous class definition uses an instance initializer to get and display the name of the class that represents the anonymous class. Thus, when the anonymous object of the anonymous class is instantiated, the text shown in Figure 8 (p. 1302) appears on the screen.

(In an earlier module explaining member classes, I told you that it is possible to examine the names of the class files that represent the member classes and to determine quite a lot about the structure of the program in terms of which classes are members of which other classes. However, in the case of local classes and anonymous classes, about all that you can determine from the name of the class file is that the file either represents a local class or represents an anonymous class (see the summary of class names in Figure 3 (p. 1301).)

The windowClosing method

The code in Listing 9 (p. 1306) overrides the `windowClosing` method inherited from the `WindowAdapter` class.

Clicking the `close` button with the X in the upper right hand corner of Figure 2 (p. 1301) causes the `windowClosing` method to be called on any `WindowListener` objects that have been registered on the frame.

In this case, the overridden `windowClosing` method in Listing 9 (p. 1306) causes the last line of text in Figure 4 (p. 1301) to be displayed on the screen.

Following that, the overridden `windowClosing` method calls the `System.exit` method to terminate the program.

The remaining code

The remaining code in Listing 9 (p. 1306)

- Causes the frame to become visible
- Signals the end of the constructor
- Signals the end of the `GUI` class

4.2.5.4.3 The GUI remains on the screen until terminated

Once the constructor is executed, the GUI simply remains on the screen waiting for someone to click one of the buttons or to click the close button in the upper right corner of the frame. When these buttons are clicked, the event handlers are called, causing text such as that shown in Figure 9 (p. 1302) to appear on the screen.

4.2.5.4.4 Simple event handlers

In this demo program, the event handlers simply display messages on the screen, and in the case of the close button, terminate the program. In a real world program, the behavior of the event handlers would likely be much more substantive, but the overall skeleton of the program need not be any different from that illustrated here.

4.2.5.5 Run the program

I encourage you to copy the code from Listing 10 (p. 1306) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.2.5.6 Summary

In addition to a number of other items, a class definition can contain:

- Member classes
- Local classes
- Anonymous classes
- Nested top-level classes and interfaces

Member classes and local classes were explained in previous modules. This module explains anonymous classes.

Although there are some differences, an anonymous class is very similar to a local class without a name. Instead of defining a local class and then instantiating it, you can often use an anonymous class to combine these two steps.

An anonymous class is defined by a Java expression, not a statement. Therefore, an anonymous class definition can be included within a larger overall Java expression.

Anonymous class definitions are often included as arguments to method calls, or as the right operand of assignment operators.

An object of an anonymous class must be internally linked to an object of the enclosing class.

There is no such thing as an anonymous interface, a local interface, or a member interface.

An anonymous class can often be defined very close to its point of use. Once you become accustomed to the somewhat cryptic syntax used with anonymous classes, this can lead to improved code readability.

Probably the most important benefit of anonymous classes has to do with accessing the members of enclosing classes. As with member classes and local classes, methods of an anonymous class have direct access to all the members of the enclosing classes, including private members. Thus the use of anonymous classes can sometimes eliminate the requirement to connect objects together via constructor parameters. In addition, objects of anonymous classes have access to **final** local variables that are declared within the scope of the anonymous class.

An anonymous class can be particularly useful in those cases where

- There is no reason for an object of the anonymous class to exist in the absence of an object of the enclosing class.
- There is no reason for an object of the anonymous class to exist outside a method of the enclosing class.
- Methods of the object of the anonymous class need access to members of the object of the enclosing class.
- Methods of the object of the anonymous class need access to **final** local variables and method parameters belonging to the method in which the anonymous class is defined.
- Only one instance of the anonymous class is needed.
- There is no need for the class to have a name that is accessible elsewhere in the program.

An anonymous class cannot define a constructor. However, it can define an instance initializer.

Any arguments that you specify between the parentheses following the superclass name in an anonymous class definition are implicitly passed to the superclass constructor.

Only one instance of an anonymous class can be created.

As with member classes and local classes, anonymous classes cannot contain **static** members.

As with local variables and local classes, anonymous classes cannot be declared **public** , **protected** , **private** , or **static** .

4.2.5.7 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java OOP: Anonymous Classes
- File: Java1640.htm
- Published: 11/20/13

Disclaimers: Financial : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

In the past, unknown individuals have copied my modules from cnx.org, converted them to Kindle books, and placed them for sale on Amazon.com showing me as the author. I neither receive compensation for those sales nor do I know who does receive compensation. If you purchase such a book, please be aware that it is a copy of a module that is freely available on cnx.org and that it was made and published without my prior knowledge.

class BaldButton extends Button{
BaldButton(String text){ //constructor
    enableEvents(AWTEvent.MOUSE_EVENT_MASK);
    setLabel(text);
    System.out.println("Local class name: " +
        getClass().getName());
} //end constructor
```

Table 4.76

Listing 4 - The processMouseEvent method.

```

public void processMouseEvent(MouseEvent e){
    if (e.getID() == MouseEvent.MOUSE_CLICKED){
        System.out.println("buttonA clicked");
    }//end if

    //The following is required of overridden
    // processMouseEvent method.
    super.processMouseEvent(e);
} //end processMouseEvent
} //end class BaldButton

//Add button to Frame
add(new BaldButton("A"));

```

Table 4.77**Listing 5 - Beginning of anonymous inner class.**

```

add(new Button("B")
{ //Begin class definition
  { //Instance initializer
    enableEvents(
      AWTEvent.MOUSE_EVENT_MASK);
    System.out.println(
      "Anonymous class B name: " +
      getClass().getName());
  } //end instance initializer

```

Table 4.78

Listing 6 - Overridden processMouseEvent method.

```
public void processMouseEvent(  
    MouseEvent e){  
if (e.getID() ==  
    MouseEvent.MOUSE_CLICKED){  
    System.out.println("buttonB clicked");  
} //end if  
  
    //Required of overridden  
    // processMouseEvent method.  
    super.processMouseEvent(e);  
} //end processMouseEvent  
} //end class definition  
); //end add method call
```

Table 4.79

Listing 7 - Register a MouseListener object.

```
Button buttonC = new Button("C");  
  
buttonC.addMouseListener(new MouseListener()  
    { //begin class definition  
        //Instance initializer  
        {System.out.println(  
            "Anonymous class C name: " +  
                getClass().getName());}  
    }  
});
```

Copyright 2003 R.G.Baldwin

This program is designed to illustrate the use of local classes, and anonymous classes. It illustrates three different implementations of anonymous classes. It also illustrates the use of instance initializers as an alternative to constructors.

Illustrates use of local class to instantiate object to handle mouse clicked event with low-level event handling. This class uses constructor to enable mouse events on a new extended Button class. Also uses constructor to display the class file name.

Illustrates use of anonymous class to instantiate object to handle mouse clicked event with low-level event handling. This class uses an instance initializer to enable mouse events on a new extended Button class. Also uses instance initializer to display name of class file.

Illustrates use of anonymous class, which implements MouseListener interface, to instantiate object to handle mouse clicked event using source-listener event model. Uses instance initializer to display name of class file.

Illustrates use of anonymous class, which extends WindowAdapter class, to instantiate object to handle window events fired by the close button in the upper-right corner of a Frame object, using source-listener event model. Uses instance initializer to display name of class file.

This program produces the following class files when compiled:

```
GUI$1$BaldButton.class
GUI$1.class
GUI$2.class
GUI$3.class
GUI.class
InnerClasses08.class
```

The program produces the following output when the program is started, each button is clicked once in succession, and then the close button in the upper-right corner of the Frame is clicked:

```

Local class name: GUI$1$BaldButton
Anonymous class B name: GUI$1
Anonymous class C name: GUI$2
Anonymous window listener class name: GUI$3
buttonA clicked
buttonB clicked
buttonC clicked
Close button clicked

4.2.6 Java1642 The Essence of OOP using Java, Nested Top-Level Classes⁵⁴

Revised: Wed May 11 16:20:00 CDT 2016

This page is included in the following Books:

⁵⁴This content is available online at <<http://cnx.org/content/m59576/1.3/>>.

- *ITSE2317 - Java Programming (Intermediate)* ⁵⁵
- *Object-Oriented Programming (OOP) with Java* ⁵⁶

4.2.6.1 Table of contents

- Preface (p. 1311)
- Tutorial and code links (p. 1311)
- Miscellaneous (p. 1311)

4.2.6.2 Preface

Over the years, I have published a large number of tutorials in the areas of computer programming and digital signal processing (DSP). As I have time available, I am converting the more significant of those tutorials into cnxml code and re-publishing them at cnx.org ⁵⁷.

In the meantime, this is one of the pages in a book titled *ITSE2317 - Java Programming (Intermediate)* ⁵⁸ that presents PDF versions of the original tutorials to make them readily available for Connexions users. When I have time available, I plan to update this tutorial and to re-publish it as a standard page at cnx.org ⁵⁹.

This tutorial may contain internal links to other tutorials that I have written and published somewhere on the web. Those links may, or may not still be good. In any event, if you search cnx.org ⁶⁰ for the tutorial by title or by topic, you will probably find a clean copy of the referenced tutorial at cnx.org ⁶¹. If not, you can probably use a Google Advanced Search ⁶² to find a copy somewhere on the web.

4.2.6.3 Tutorial and code links

Click here ⁶³ to download and view the PDF version of this page.

The representation of program code in PDF documents is often very unreliable. Click here ⁶⁴ to download a zip file containing a clean copy of the program code discussed in this tutorial.

4.2.6.4 Miscellaneous

This section contains a variety of miscellaneous information.

4.3.1.2 Preface

This module is one in a collection of modules on Java Generics designed for teaching *ITSE2317 - Java Programming (Intermediate)* at Austin Community College in Austin, TX.

Many new features in Java version 1.5

When Java version 1.5 was released, it contained many new language features, including:

- Generics
- Enhanced for Loop
- Autoboxing/Unboxing
- Typesafe Enums
- Varargs
- Static Import
- Metadata

In addition to the new language features, Java version 1.5 also contained other new features such as new *Look and Feel* capabilities for Swing GUIs.

First in a series

This is the first module in a series of modules designed to teach you about Generics in Java version 1.5. This module will teach you some of the rudimentary aspects of the generics capability . This module will also teach you how to use the *enhanced for loop* with collections.

Future modules will teach you how to use other aspects of generics

4.3.1.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and the Listings while you are reading about them.

4.3.1.2.1.1 Figures

- Figure 1 (p. 1315) . Typical v1.5 compiler warning.
- Figure 2 (p. 1315) . Warning with -Xlint:unchecked.
- Figure 3 (p. 1319) . A ClassCastException.
- Figure 4 (p. 1322) . A compiler error.
- Figure 5 (p. 1324) . Iterator output.

4.3.1.2.1.2 Listings

- Listing 1 (p. 1323) . Beginning of the program named Generics05.
- Listing 2 (p. 1323) . Beginning of the runIt method.
- Listing 3 (p. 1324) . An iterator.
- Listing 4 (p. 1325) . Enhanced for loop.
- Listing 5 (p. 1327) . The program named Generics01.
- Listing 6 (p. 1328) . The program named Generics02.
- Listing 7 (p. 1329) . The program named Generics03.
- Listing 8 (p. 1330) . The program named Generics04.
- Listing 9 (p. 1331) . The program named Generics05.

4.3.1.3 General background information

A new compiler warning

Have you recently tried to recompile a legacy program that has compiled and executed properly for many years only to get a compiler message similar to that shown in Figure 1 (p. 1315) ?

Figure 1 - Typical v1.5 compiler warning.

Note: Generics01.java uses unchecked or unsafe operations.
 Note: Recompile with -Xlint:unchecked for details.

Table 4.83

If you followed up and recompiled as directed, you probably got a message from the compiler that looked something like the one shown in Figure 2 (p. 1315) .

Figure 2 - Warning with -Xlint:unchecked.

```
Generics01.java:34: warning: [unchecked] unchecked call to add(E) as a member of
the raw type ArrayList
    var1.add(new Date());
           ^
where E is a type-variable:
    E extends Object declared in class ArrayList
1 warning
```

Table 4.84

If that has happened to you, you have had your first encounter with a new feature in Java version 1.5 known as *generics*.

What are generics?

Oracle has this to say about generics (*boldface added for emphasis*):

*"This long-awaited enhancement to the type system allows a type or method to operate on objects of various types while providing **compile-time type safety** . It adds compile-time type safety to the Collections Framework and eliminates the drudgery of casting."*

In addition to the Collections Framework, generics impacts several other areas of Java programming as well.

Generics are not particularly easy

Don't be lulled into a false sense of security by what you will find in this module. Although the introductory material presented in this module is rather straightforward, a full understanding of generics can be fairly difficult. The tentacles of generics reach into many different areas of Java in very complex ways.

The truth of this is borne out by the fact that the excellent book entitled Java How to Program, Sixth Edition (Deitel) ⁶⁹ dedicates an entire chapter consisting of more than 30 pages to generics. Furthermore, the chapter on generics doesn't even include many additional pages that the book dedicates to a discussion of the impact of generics on the Java Collections Framework. The book covers several topics in the chapter on generics, including the following:

- Generic methods
- Generic classes
- Raw types

⁶⁹http://www.amazon.com/exec/obidos/ASIN/0131483986/qid=1110389658/sr=11-1/ref=sr_11_1/102-4105266-9447324

- Wildcards
- Generics and inheritance

The impact of generics on the Java Collections Framework is covered in a different chapter. Hopefully, the benefits provided by generics will outweigh the additional complexity. Only time will tell.

The Java Collections Framework

Even though the material that will be presented in this module will be relatively straightforward, you will need to know something about the Java Collections Framework for it to make much sense. If you need to learn more about the Java Collections Framework, see the modules beginning with Java4010: Getting Started with Java Collections ⁷⁰ at I TSE 2321 - Object-Oriented Programming (Java) ⁷¹. Be aware, however, that those modules were originally published long before generics existed in Java. If you compile the programs in those modules using Java version 1.5 or a later version, you will get the warning messages from the compiler shown in Figure 1 (p. 1315).

4.3.1.4 Preview

I will present and explain several very simple programs in this module. Those programs are intended to illustrate the following concepts:

- How the Java Collections Framework behaved prior to the release of Java version 1.5.
- The effect of an incorrect cast in code that doesn't use generics.
- Avoiding the requirement to cast through the use of generics. This program also includes an illustration of some of the required syntax for generics.
- Compile-time type safety provided by the use of generics.
- Syntax requirements for the use of iterators with generics. This program also illustrates the use of the enhanced **for** loop with collections, which is another new feature in Java version 1.5.

4.3.1.5 Discussion and sample code

Listings of the programs

Complete listings of all the programs discussed in this module are provided in Listing 5 (p. 1327) through Listing 9 (p. 1331) near the end of the module.

4.3.1.5.1 Collection behavior prior to Java version 1.5

The main purpose of the program named **Generics01** is to establish a baseline against which to compare the other programs. A secondary purpose is to illustrate the warnings produced by the Java version 1.5 (*or later*) compiler when the syntax of the source code doesn't take generics into account.

A complete listing of the program named **Generics01** is shown in Listing 5 (p. 1327) near the end of the module.

As you will see later, this program was written using the program syntax and style that was common prior to the release of Java version 1.5. In particular, this program does not include the syntax necessary to take generics into account.

Notes at compile time

When this program is compiled using the Java version 1.5 or later compiler, the text shown in Figure 1 (p. 1315) appears on the screen.

Note that the text in Figure 1 (p. 1315) is not identified as either an error or a warning. Rather, the text is identified simply as notes. These notes provide instructions on how to recompile and get more information regarding a potential problem.

Recompiling with the Xlint switch

⁷⁰<http://cnx.org/contents/dzOvxPFw:BaPSYll8>

⁷¹<http://cnx.org/contents/dzOvxPFw>

When the program is recompiled using the `Xlint` switch shown in Figure 1 (p. 1315) , the compiler produces the text shown in Figure 2 (p. 1315) . Note that this text is identified as a warning.

*(Later when we examine the code from the program named **Generics01** , you can compare it with this text to see just what the compiler is complaining about.)*

Get used to it

The text in Figure 1 (p. 1315) and Figure 2 (p. 1315) is similar to what you can expect to see any time that you use the Java version 1.5 or later compiler to compile a program that includes the Java Collections Framework and doesn't use the required syntax to take generics into account. This probably includes many of the programs that you wrote, compiled, and executed successfully prior to the release of Java version 1.5.

The program code

The code for the program named **Generics01** is shown in its entirety in Listing 5 (p. 1327) .

The main method

As you can see in Listing 5 (p. 1327) , the **main** method instantiates a new object of the class named **Generics01** , and calls the method named **runIt** on that object. It is the behavior of the **runIt** method that interests us. More particularly, it is the expression contained in the argument list for the **println** method that interests us the most.

A baseline program

As mentioned earlier, the main purpose of this program is to establish a baseline against which we can compare the other programs to be discussed later. This program was written exactly as it would have been written prior to the release of generics in Java version 1.5.

An **ArrayList** object

The program declares and initializes an instance variable named **var1** with a reference to an object instantiated from the class named **ArrayList** . **ArrayList** is one of the concrete implementations of the interfaces provided in the Java Collections Framework. Briefly, an object of the **ArrayList** class is an object that implements the **List** interface, providing a convenient place to store references to other objects.

One of the methods of an **ArrayList** object is the method named **add** . This method is used to add new elements to the end of the list.

Adding a **Date** object's reference to the list

Listing 5 (p. 1327) calls the **add** method to add a new **Date** object's reference to the list.

(This is the method call that the compiler was complaining about in the warning in Figure 2 (p. 1315) .)

When an object's reference is added to an **ArrayList** object (*without the use of generic syntax*), that reference is automatically converted to and stored as type **Object** .

(As you will see later, that is probably also true even with the use of generic syntax. I will have more to say about this later.)

What can you do with a reference of type **Object**?

I often tell my students that there are only twelve things that you can do with an object's reference that has been converted to type **Object** . The first eleven of those twelve things is to call any one of the eleven methods that are defined in the **Object** class and inherited into all subclasses of **Object** . The twelfth thing is to attempt to cast the reference to some other type in an attempt to call some other method on the reference after casting.

Invoking **getTime** on the reference

The objective of the code in this program is to call the method named **getTime** on the **Date** object's reference. The **getTime** method is not one of the eleven methods that are defined in the **Object** class. Rather, the **getTime** method is defined in the **Date** class.

Change the type of the reference

Therefore, in order to call the `getTime` method on the reference after it is retrieved from the `ArrayList` object, the type of the reference must be converted from type `Object` to type `Date`. This is accomplished by the cast operation in the expression contained in the argument list for the `println` method in Listing 5 (p. 1327).

That expression calls the `get` method on the reference to the `ArrayList` object to retrieve the element stored at index 0 of the collection. The `get` method returns the reference as type `Object` (*at least that was true prior to the introduction of generics*). Then the expression casts the reference to type `Date`, converting its type back to type `Date`.

Invoking the `getTime` method

Finally, the expression successfully calls the `getTime` method on the reference of type `Date`.

The program produces an output similar to that shown below:

```
1377991758665
```

This is the number of milliseconds since January 1, 1970, 00:00:00 GMT represented by the `Date` object.

Casting was a necessity prior to Java version 1.5

Prior to the release of Java version 1.5, it was always necessary to cast references retrieved from collection objects in order to call any methods on them other than the eleven methods defined in the `Object` class.

Some authors refer to this casting requirement as "*the drudgery of casting*," and indicate that casting may be eliminated through generics.

(In my opinion, from this viewpoint alone, the cure is worse than the disease. Casting syntax is much simpler and more straightforward than generics syntax.)

May eliminate runtime errors and exceptions

However, it is possible for the programmer to perform an incorrect cast at this point in the program, which will usually result in a `ClassCastException` being thrown at runtime.

The great promise of generics is that it can sometimes cause programming errors to be recognized at compile time instead of encountering them at runtime.

Obviously, the best approach is to avoid writing programs containing programming errors in the first place. However, if you are going to write programs containing errors, it is usually better to catch them at compile time than to have them occur at runtime. This is the thing that may make the complexity of generics worthwhile.

4.3.1.5.2 An incorrect cast in code that doesn't use generics

The program named `Generics02` (*shown later in Listing 6 (p. 1328)*) illustrates the application of an incorrect cast to an element that is retrieved from an `ArrayList` object, along with the runtime error that is produced by that incorrect cast.

No compiler error

This program does not produce a compiler error.

(However, the Java version 1.5 compiler does produce a warning having to do with the failure to apply the new generics syntax that was released in Java version 1.5. Note that earlier compilers would not have produced such a warning.)

The point here is that the compiler does not check to confirm that the correct cast is applied. This results in a successful compilation, but the program throws an exception at runtime.

A `ClassCastException`

The runtime exception that is thrown by this program is shown in Figure 3 (p. 1319). You can compare the details of this exception with the program code later. The reference to line 46 in Figure 3 (p. 1319) is a reference to the statement in Listing 6 (p. 1328) that attempts to cast the reference to type `Date`. (*That reference was originally a reference to an object of type `String`.*)

Figure 3 - A ClassCastException.

```
Exception in thread "main" java.lang.ClassCastException:
  java.lang.String cannot
  be cast to java.util.Date
    at Generics02.runIt(Generics02.java:46)
    at Generics02.main(Generics02.java:53)
```

Table 4.85**The program code**

The program is shown in its entirety in Listing 6 (p. 1328) . As before, the **main** method instantiates an object of the **Generics02** class and calls the **runIt** method on that object. Also as in the previous program, this program instantiates a new **ArrayList** object and saves the object's reference in the instance variable named **var1** .

The runIt method

The **runIt** method begins by populating the **ArrayList** object with references to two different objects of different types. One of the objects is type **Date** . The other object is type **String** .

A questionable programming style

While this is probably not a very good programming style, it is a style that was commonly used by Java programmers prior to the advent of generics. It was common to populate collection objects with references to a mixture of objects of different types.

References are stored as type Object

As you already know, when these object's references are put into the collection, the types of all the references are automatically converted to type **Object** . As you also already know, when the references are retrieved from the collection, if the purpose is to call any method on a reference other than one of the eleven methods defined in the **Object** class, it is necessary to cast the reference to a type that is consistent with the method.

Casting errors are likely

This is a scenario where the programmer is likely to make a casting error when casting elements retrieved from the collection. Unless the programmer uses the **instanceof** operator to determine the type of a retrieved reference prior to performing the cast, the programmer is depending on his memory to know the type of each reference in the population on the basis of the index of the element. If the programmer loses track of the types of the different references with respect to the element's indices, a casting error is a strong possibility.

The error scenario

This is the error scenario depicted by the first call to the **println** method in Listing 6 (p. 1328) . In this case, the element at index 0 is a reference to a **Date** object, and the element at index 1 is a reference to a **String** object. However, the programmer mistakenly retrieves the element at index 1 and attempts to cast it to type **Date** , which is the type of the reference at index 0. This results in the runtime exception shown in Figure 3 (p. 1319) .

Of course, it has always been possible to use the **instanceof** operator to confirm the type of a reference before performing a cast as a way to avoid this type of programming error. Good programming practice would dictate the use of that construct when working with references to objects of mixed types in a single collection.

4.3.1.5.3 Dealing with angle brackets in cxml body text

You are reading this module at cnx.org. Documents published at cnx.org are maintained in a special flavor of xml know as cxml. Without getting into the details, I will tell you that creating cxml is not an easy

task. In order to avoid having to write these modules in raw cxml code, I originally write them using a WYSIWYG xhtml editor and then run the xhtml files through a program of my own design that transforms the xhtml document into cxml.

Unfortunately, my transform program is incapable of handling angle brackets in the body text of the document. Therefore, whenever the body text in this document needs a left angle bracket, I will indicate the existence of a left or right angle bracket using a text description of the angle bracket. The code in the listings, however, will show the left and right angle brackets intact as required.

4.3.1.5.4 Avoiding the requirement to cast through the use of generics

The program named **Generics03** shown in Listing 7 (p. 1329) illustrates how generics can be used to avoid the requirement to cast references when they are retrieved from a collection.

(While casting is not difficult, avoiding the requirement to cast can also avoid the possibility of casting incorrectly.)

As in the previous programs, the **main** method in this program instantiates an object of the class named **Generics03** and calls the method named **runIt** on the object.

Instantiate an ArrayList object

Also, as in the previous programs, this program declares an instance variable named **var1** and initializes that variable with a reference to a new object of type **ArrayList**. However, the syntax that is used for this purpose in this program is significantly different from the syntax used for the same purpose in the previous two programs.

*(Note the code in Listing 7 (p. 1329) that shows the type **Date** enclosed in matching angle brackets. This is the primary syntax change required to use generics.)*

What does this syntax mean?

One way to think of this syntax is that the expression on the right of the assignment operator instantiates a new **ArrayList** object that is capable of containing only references to objects of type **Date**.

*(Those references are probably still stored as type **Object**. We will see how this apparent discrepancy is reconciled later through automatic casting.)*

Similarly, the expression on the left of the assignment operator is the declaration of an instance variable capable of holding a reference to an **ArrayList** object, which in turn is capable of containing only references to objects of type **Date**.

Must qualify both expressions

Additional changes to generics were made in the release of Java version 1.7. Prior to the release of Java version 1.7, it was necessary to qualify the expressions on both sides of the assignment operator by use of the angle-bracket syntax. If the qualifier was included in the expression on the right, but was omitted from the variable declaration on the left, the compilation would fail later. That is still true following the release of Java version 1.7.

If the angle-bracket qualifier was included with the variable declaration on the left and omitted from the instantiation of the new object on the right, the program would compile and run successfully. However, the compiler would issue an *unchecked conversion* warning indicating the possibility of a runtime error under certain conditions.

Following the release of Java version 1.7, it is not necessary to qualify the expression on the right side of the assignment operator. You will learn more about this in a future module.

What does Oracle have to say?

According to Oracle (*boldface added for emphasis*),

*"Generics provides a way for you to communicate the type of a collection to the compiler, so that it can be checked. Once the compiler knows the element type of the collection, the compiler can check that you have used the collection consistently and **can insert the correct casts** on values being taken out of the collection."*

Note the boldface text in the above quotation indicating that the compiler modifies your code by inserting casts where appropriate.

Compile-time type safety

In discussing code similar to the code in Listing 7 (p. 1329) , Oracle states,

*"... so the compiler can verify at compile time that the type constraints are not violated at run time. Because the program compiles without warnings, we can state with certainty that it will not throw a **ClassCastException** at run time. The net effect of using generics, especially in large programs, is improved readability and robustness."*

In order to achieve compile-time type safety, it is necessary that the program compiles without warnings. Otherwise, the program may execute, but may throw a **ClassCastException** at runtime.

More on generics with collections

In further explaining generics as used with collections, Oracle goes on to say (*boldface added for emphasis*):

*"... when we declare *c* to be of type *Collection* (*String* in angle brackets), this tells us something about the variable *c* that holds true wherever and whenever it is used, and the compiler guarantees it (assuming the program **compiles without warnings**). A cast, on the other hand, tells us something the programmer thinks is true at a single point in the code, and the VM checks whether the programmer is right only at run time."*

The bottom line

The bottom line on generics (*when used with collections*) seems to be that references to objects are still stored in the collection as type **Object** . However, when we notify the compiler of the type of data to be stored in the collection using angle-bracket syntax, and the program compiles without warnings, the compiler will do at least the following:

- Ensure that only references to objects of the specified type are stored in the collection, and used consistently throughout the program, thus eliminating the possibility of a **ClassCastException** at runtime.
- Automatically cast the reference to the specified type when it is later retrieved by program code.

No explicit cast is required

That brings us back to a discussion of the code in Listing 7 (p. 1329) . Note that unlike the code in Listing 5 (p. 1327) , the print statement in Listing 7 (p. 1329) does not contain an explicit cast to type **Date** , (*at least not in the code that I wrote*).

As described above, having been notified that the collection can contain only references to objects of type **Date** , the compiler automatically inserted a cast to type **Date** at the appropriate place in the code, thereby guaranteeing that the reference is converted from type **Object** to type **Date** before the **getTime** method is called on the reference.

There is still a cast involved. However, the cast is automatically inserted by the compiler. This eliminates the requirement for me (*the programmer*) to insert the cast, and also eliminates the possibility of me inserting an incorrect cast.

Once again, all of this assumes that the program compiles without warnings.

Program output

The program in Listing 7 (p. 1329) compiles and executes correctly, producing the following output for one particular run.

1377995720768

4.3.1.5.5 Compile-time type safety provided by the use of generics

The program named **Generics04** shown in Listing 8 (p. 1330) illustrates the ability of generics to prevent the storing of the wrong type of references in a collection. This in turn can prevent runtime errors.

A new **ArrayList** object

Listing 8 (p. 1330) instantiates a new object of type **ArrayList** capable of storing only references to objects of type **Date**. This object's reference is stored in the instance variable named **var1**.

Other types cannot be stored in the collection

Once the **ArrayList** has been constrained to contain only references to objects of type **Date**, the compiler will not allow a reference to an object of any other type (*other than types that are assignment compatible with **Date**, such as subclasses of **Date***) to be stored in the collection.

A compiler error rather than a runtime error

The first statement in the **runIt** method in Listing 8 (p. 1330) attempts to add a new element to the **ArrayList** object. The new element is a reference to a literal **String** object that encapsulates the string "abcd". This results in the compiler error shown in Figure 4 (p. 1322).

Figure 4 - A compiler error.

```
Generics04.java:34: error: no suitable method found for add(String)
    var1.add("abcd");
         ^
    method ArrayList.add(int,Date) is not applicable
      (actual and formal argument lists differ in length)
    method ArrayList.add(Date) is not applicable
      (actual argument String cannot be converted to Date by method invocation
      conversion)
1 error
```

Table 4.86

Without the use of generics, a reference to an object of any type could be added to the collection. This could result in a runtime error later if the programmer expected an object of type **Date** when in fact the object is of type **String**. If you are going to write programs containing errors, compiler errors are almost always preferable to runtime errors.

4.3.1.5.6 Generic iterator syntax and the enhanced for loop

Iterators

Listing 7 (p. 1329) and Listing 8 (p. 1330) showed the syntax that you must use to cause a collection object to be treated as a generic collection. You must also use a special syntax when working with generic iterators and the Java Collections Framework.

The enhanced for loop

Another new feature of Java version 1.5, referred to by Oracle as an *enhanced for loop*, can be used in certain situations to provide most of the benefits of an iterator with a somewhat simpler syntax.

(The enhanced for loop is also sometimes referred to as a for-each loop.)

The program named **Generics05**, which begins in Listing 1 (p. 1323), illustrates both of these concepts. A complete listing of the program is provided in Listing 9 (p. 1331).

Listing 1 - Beginning of the program named Generics05.

```
import java.util.*;

public class Generics05{
    //Create an ArrayList object suitable for
    // storing references to Date objects.
    ArrayList <Date> var1 = new ArrayList<Date>();
```

Table 4.87**The main method**

As in the previous programs, the **main** method instantiates an object of the **Generics05** class and calls the **runIt** method on that object. You can view the **main** method in Listing 9 (p. 1331) near the end of the module.

Instantiate a generic ArrayList object

This program is a little longer than the previous programs, so I will break it down and explain it in fragments.

Listing 1 (p. 1323) shows the beginning of the **Generics05** class. The code in Listing 1 (p. 1323) instantiates a new **ArrayList** object capable of storing references to objects of type **Date** only. The code in Listing 1 (p. 1323) also saves that object's reference in a generic instance variable named **var1**. This is the same syntax that you have seen in previous listings.

Populate the collection

Listing 2 (p. 1323) shows the beginning of the **runIt** method. This code populates the **ArrayList** object with references to three **Date** objects. The first object encapsulates the current date and time. The second object encapsulates the date and time one day later than the first. The third object encapsulates the date and time two days later than the first object.

Listing 2 - Beginning of the runIt method.

```
void runIt(){
    //Get current date and time in milliseconds.
    long now = new Date().getTime();
    //Get length of one day in milliseconds
    long oneDay = 24 * 60 * 60 * 1000;

    //Populate the ArrayList object
    var1.add(new Date(now));
    var1.add(new Date(now + oneDay));
    var1.add(new Date(now + 2 * oneDay));
```

Table 4.88

The code in Listing 2 (p. 1323) is straightforward and shouldn't require further explanation.

Get and use an iterator

An iterator is an object instantiated from a specially designed class that implements the **Iterator** interface. The design of the class makes it possible for client code to gain sequential access to each element

encapsulated in an associated collection object without a requirement to know anything about how the collection is structured.

Required syntax

The first statement in Listing 3 (p. 1324) shows the syntax required to get and save a reference to a generic iterator for the **ArrayList** object instantiated earlier in Listing 1 (p. 1323) .

Listing 3 - An iterator.

```
//Get an iterator
Iterator <Date> iter = var1.iterator();

//Perform the iteration
while(iter.hasNext()){
    System.out.println(iter.next().getTime());
}

} //end while loop

System.out.println();//blank line
```

Table 4.89

Note the requirement to qualify the declaration of the local variable named **iter** with the type of data stored in the collection using angle-bracket notation similar to that used earlier.. You might think of this as a variable capable of holding a reference to an iterator object, which is capable of iterating on an **ArrayList** object, which in turn is capable of storing references to objects of type **Date** only.

Perform the iteration

The remaining code in Listing 3 (p. 1324) uses the iterator to sequentially access and display information encapsulated in each of the three **Date** objects whose references are stored in the **ArrayList** object. This is standard code for the use of an iterator and should not require further explanation. This code produces the first three lines of text (*plus the blank line*) shown in Figure 5 (p. 1324) .

Figure 5 - Iterator output.

```
1378070280877
1378156680877
1378243080877

1378070280877
1378156680877
1378243080877
```

Table 4.90

The program output

The output produced by this program depends on when you run it. The output produced for one particular run is shown in Figure 5 (p. 1324) .

The output will be different each time you run the program depending on the current date and time.

The enhanced for loop

The code in Listing 4 (p. 1325) performs the same iteration using the new enhanced **for** loop that was released in Java version 1.5.

Listing 4 - Enhanced for loop.

```
//Now perform the same iteration using
// the new for-each construct.
for(Date element : var1){
    System.out.println(element.getTime());
} //end for-each

} //end runIt
```

Table 4.91

You might think of this syntax as meaning:

*For each element of type **Date** contained in the collection referred to by **var1**, get the value of the element and save it in the variable named **element**. Then use the contents of that variable to perform the operations specified within the body of the loop.*

More compact syntax

As you can see, this approach does not require you to get an iterator and to explicitly use that iterator to sequentially access the elements in the collection. Thus, the syntax is more compact than the syntax shown in Listing 3 (p. 1324). Further, by eliminating the requirement to get the iterator, this construct also eliminates the requirement for you to qualify the code using the angle-bracket syntax. All of those details are handled automatically behind the scenes.

Not quite as powerful as an iterator

Although not shown in Listing 3 (p. 1324), the use of an iterator allows you to remove the most recently accessed element from a collection. As near as I can tell, the enhanced **for** loop does not provide that capability. Therefore, the enhanced **for** loop is not quite as powerful as an iterator. However, if you don't need to remove elements from the collection, the enhanced **for** loop appears to be a good and somewhat simpler alternative to an iterator.

The output

The code in Listing 4 (p. 1325) produced the last three lines of text in the output shown in Figure 5 (p. 1324). Obviously the last three lines match the first three lines since they simply represent different ways to produce a text representation of the same three **Date** objects.

4.3.1.6 Run the programs

I encourage you to copy the code from Listing 5 (p. 1327) through Listing 9 (p. 1331) Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.3.1.7 Summary

In this module, I explained:

- How the Java Collections Framework behaved prior to the release of Java version 1.5.
- The effect of an incorrect cast in code that doesn't use generics.
- How to avoid the requirement to cast through the use of generics, including an illustration of some of the required syntax for generics.
- The compile-time type safety provided by the use of generics.
- The syntax requirements for the use of iterators with generics.
- The use of the enhanced **for** loop with collections.

4.3.1.8 What's next?

Future modules in this series will be based on the Generics (Updated) ⁷² section of The Java Tutorials ⁷³ from Oracle. *(In the event that these links become broken, you should have no difficulty finding the Oracle material with an online search.)*

Those modules will teach you about other aspects of generics including:

- Generic methods
- Generic classes
- Raw types in generics
- Wildcards and bounded wildcards in generics
- The impact of inheritance on generics

4.3.1.9 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

4.3.1.10 Complete program listings

Complete listings of the programs discussed in this module are provided below.

Listing 5 - The program named Generics01.

```

/*File Generics01.java
Copyright 2005, R.G.Baldwin

Illustrates requirement to cast without the use
of generics.

V1.5 compiler produces following warning:

Note: Generics01.java uses unchecked or unsafe
operations.
Note: Recompile with -Xlint:unchecked for
details.

Recompilation with -Xlint:unchecked produces
the following output:

Generics01.java:34: warning: [unchecked] unchecked
call to add(E) as a member of
the raw type ArrayList
    var1.add(new Date());
            ^
    where E is a type-variable:
      E extends Object declared in class ArrayList
1 warning

Tested using JDK 1.7 under Win 7.
*****/

import java.util.*;

public class Generics01{

    ArrayList var1 = new ArrayList();

    void runIt(){
        var1.add(new Date());
        //Note the required cast in the following
        // statement.
        System.out.println(
            ((Date)var1.get(0)).getTime());
    }//runIt

    public static void main(String[] args){
        new Generics01().runIt();
    }//end main

```

```
}//end class Generics01
//=====//
```

Listing 6 - The program named Generics02.

```
/*File Generics02.java
Copyright 2005, R.G.Baldwin
```

Illustrates the application of an incorrect cast to an element that is fetched from an ArrayList object and the runtime error produced by that incorrect cast.

This program does not produce a compiler error, although the v1.5 compiler does produce a general warning having to do with the failure to apply the new generics syntax released in v1.5. (Earlier compilers would not have produced such a warning.)

However, the compiler does not check to confirm that the correct cast is applied. This results in the following runtime error when an incorrect cast is applied:

```
Exception in thread "main" java.lang.ClassCastException: java.lang.String cannot
be cast to java.util.Date
    at Generics02.runIt(Generics02.java:46)
    at Generics02.main(Generics02.java:53)
```

Tested using JDK 1.7 under Win 7.

```
*****/
```

```
import java.util.*;

public class Generics02{

    ArrayList var1 = new ArrayList();

    void runIt(){
        var1.add(new Date());
        var1.add("abcd");
        //Note that the (Date) cast is applied to
        // an element of type String in the following
        // statement, producing a runtime error. The
        // problem is that the wrong index was used
        // in fetching the element. Thus, the wrong
        // element was fetched.
```

```

    System.out.println(
        ((Date)var1.get(1)).getTime());
    System.out.println(
        ((String)var1.get(1)).length());
} //end runIt

public static void main(String[] args){
    new Generics02().runIt();
} //end main

} //end class Generics02
//=====//

```

Listing 7 - The program named Generics03.

```

/*File Generics03.java
Copyright 2005, R.G.Baldwin

Illustrates use of generics to avoid requirement
to cast. Requires v1.5 or later.

Program output for one run was:

1377995720768

Tested using JDK 1.7 under Win 7.
*****/

import java.util.*;

public class Generics03{

    ArrayList <Date> var1 = new ArrayList<Date>();

    void runIt(){
        var1.add(new Date());
        //Note that no cast is required in the
        // following statement.
        System.out.println(var1.get(0).getTime());
    } //end runIt

    public static void main(String[] args){
        new Generics03().runIt();
    } //end main

} //end class Generics03
//=====//

```

Table 4.92

Listing 8 - The program named Generics04.

```

/*File Generics04.java
Copyright 2005, R.G.Baldwin

Illustrates ability of generics to prevent
storing of wrong type in a collection.
Requires v1.5 or later.

Compilation produces following error message:

Generics04.java:34: error: no suitable method
found for add(String)
    var1.add("abcd");
        ^
    method ArrayList.add(int,Date) is not
    applicable (actual and formal argument lists
    differ in length)
    method ArrayList.add(Date) is not applicable
    (actual argument String cannot be converted
    to Date by method invocation conversion)
1 error

Once the ArrayList has been declared to be of
type Date, it is not possible to add an element
of type String. An attempt to do so produces
a compiler error.

Tested using JDK 1.7 under Win 7.
*****/

import java.util.*;

public class Generics04{

    ArrayList <Date> var1 = new ArrayList<Date>();

    void runIt(){
        var1.add("abcd");
        System.out.println(var1.get(0).getTime());
    }//end runIt

    public static void main(String[] args){
        new Generics04().runIt();
    }//end main

} //end class Generics04
//=====//

```

Table 4.93

Listing 9 - The program named Generics05.

```

/*File Generics05.java
Copyright 2005, R.G.Baldwin

Illustrates required syntax for using an iterator
with generics. Also illustrates the new for-each
construct in Java 5.0

Output for one particular run is shown below.

1378070280877
1378156680877
1378243080877

1378070280877
1378156680877
1378243080877

Output will be different each time the program
is run depending on the current date and time.

Tested using JDK 1.7 under Win 7.
*****/

import java.util.*;

public class Generics05{
    //Create an ArrayList object suitable for
    // storing references to Date objects.
    ArrayList <Date> var1 = new ArrayList<Date>();

    void runIt(){
        //Get current date and time in milliseconds.
        long now = new Date().getTime();
        //Get length of one day in milliseconds
        long oneDay = 24 * 60 * 60 * 1000;

        //Populate the ArrayList object
        var1.add(new Date(now));
        var1.add(new Date(now + oneDay));
        var1.add(new Date(now + 2 * oneDay));

        //Get an iterator
        Iterator <Date> iter = var1.iterator();

        //Perform the iteration
        while(iter.hasNext()){

```

```
        System.out.println(iter.next().getTime());

    }//end while loop

    System.out.println();//blank line

    //Now perform the same iteration using
    // the new for-each construct.
    for(Date element : var1){
        System.out.println(element.getTime());

    }//end for-each

} //end runIt

public static void main(String[] args){
    new Generics05().runIt();
} //end main

} //end class Generics05
//=====//
```

4.3.2.2 Preface

This module contains review questions and answers keyed to the module titled Java4210: Getting Started with Generics ⁷⁷ .

The questions and the answers are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

4.3.2.3 Questions

4.3.2.3.1 Question 1 .

True or False: When Java version 1.5 was released, it contained many new language features, including:

- Generics
- Enhanced for Loop
- Autoboxing/Unboxing
- Collections
- Typesafe Enums
- Varargs
- Static Import
- Metadata

Answer 1 (p. 1349)

4.3.2.3.2 Question 2

True or False: Using Java version 1.7, the code shown in Listing 1 (p. 1335) will compile without warnings, errors, or other messages being generated by the compiler.

⁷⁷<http://cnx.org/contents/Rl23r3Lw:Ss0r2-1m>

Listing 1 - Question 2

```

/*File Q02.java
*****/

import java.util.*;

public class Q02{

    ArrayList var1 = new ArrayList();

    void runIt(){
        var1.add(new Date());
        //Note the required cast in the following
        // statement.
        System.out.println(
            ((Date)var1.get(0)).getTime());

    }//runIt

    public static void main(String[] args){
        new Q02().runIt();
    }//end main

}//end class Q02
//=====//

```

Table 4.94

Answer 2 (p. 1349)

4.3.2.3.3 Question 3

Generics was introduced in Java v1.5 to provide which of the following:

- A. Code simplicity
- B. Compile-time type safety
- C. A clear and straightforward code syntax.
- D. None of the above.

Answer 3 (p. 1349)

4.3.2.3.4 Question 4

True or False: The use of generics is limited to the Java Collections framework.

Answer 4 (p. 1349)

4.3.2.3.5 Question 5

True or False: The Java v1.7 compiler produces an error message when an attempt is made to compile the code shown in Listing 1 (p. 1335) .

Answer 5 (p. 1348)

4.3.2.3.6 Question 6

True or False: When the code in Listing 1 (p. 1335) is compiled using the **-Xlint:unchecked** switch with Java v1.7, the compiler produces:

- A. An error message
- B. A warning
- C. None of the above

Answer 6 (p. 1348)

4.3.2.3.7 Question 7

True or False: The program code shown in Listing 2 (p. 1336) will compile and execute successfully to produce an output similar to that shown in Figure 1 (p. 1336) .

Listing 2 - Question 7.

```

    /*File Q07.java
    *****/

import java.util.*;

public class Q07{

    ArrayList var1 = new ArrayList();

    void runIt(){
        var1.add(new Date());
        System.out.println(
            (var1.get(0)).getTime());

    }//runIt

    public static void main(String[] args){
        new Q07().runIt();
    }//end main

} //end class Q07
//=====//

```

Table 4.96

Answer 7 (p. 1348)

4.3.2.3.8 Question 8

What modification must be made to the code shown in Listing 2 (p. 1336) to cause it to compile and execute successfully?

Answer 8 (p. 1347)

4.3.2.3.9 Question 9

True or False: The program code shown in Listing 3 (p. 1337) will compile and execute successfully to produce an output similar to that shown in Figure 2 (p. 1338) .

Listing 3 - Question 9.

```

/*File Q09.java
*****

import java.util.*;

public class Q09{

    ArrayList var1 = new ArrayList();

    void runIt(){
        var1.add(new Date());
        var1.add("abcd");
        System.out.println(
            ((Date)var1.get(1)).getTime());
        System.out.println(
            ((String)var1.get(1)).length());
    }//end runIt

    public static void main(String[] args){
        new Q09().runIt();
    }//end main

} //end class Q09
//=====//

```

Table 4.97

1378056276557
4

Table 4.98

Answer 9 (p. 1346)

4.3.2.3.10 Question 10

The code shown in Listing 4 (p. 1338) will not compile and run successfully. Without using a cast operator, what changes can you make to the class named Q10 to cause the program to compile and run successfully and to produce the current time in milliseconds?

Listing 4 - Question 10.

```

/*File Q10.java
*****/

import java.util.*;

public class Q10{

    ArrayList var1 = new ArrayList();

    void runIt(){
        var1.add(new Date());
        //Note the required cast in the following
        // statement.
        System.out.println(
            (var1.get(0)).getTime());

    }//runIt

    public static void main(String[] args){
        new Q10().runIt();
    }//end main

} //end class Q10
//=====//

```

Table 4.99

Answer 10 (p. 1345)

4.3.2.3.11 Question 11

True or False: Using Java v1.7, even with the empty angle brackets shown in the instantiation of the ArrayList object in Listing 5 (p. 1339) , the program in Listing 5 (p. 1339) will compile and run successfully with no notes, warnings, errors, or other complaints from the compiler. The program will produce an output similar to that shown in Figure 3 (p. 1339) .

Listing 5 - Question 11.

```

/*File Q11.java
*****/

import java.util.*;

public class Q11{

    ArrayList <Date> var1 = new ArrayList<>();

    void runIt(){
        var1.add(new Date());
        //Note the required cast in the following
        // statement.
        System.out.println(
            (var1.get(0)).getTime());

    }//runIt

    public static void main(String[] args){
        new Q11().runIt();
    }//end main

} //end class Q11
//=====//

```

Table 4.100**Figure 3 - Question 11.**

1378059224125

Table 4.101

Answer 11 (p. 1345)

4.3.2.3.12 Question 12

True or False: The program shown in Listing 6 (p. 1340) will compile and run successfully producing an output similar to that shown in Figure 4 (p. 1340) .

Listing 6 - Question 12.

```

/*File Q12.java
*****

import java.util.*;

public class Q12{

    ArrayList <Date> var1 = new ArrayList<Date>();

    void runIt(){
        var1.add("abcd");

        System.out.println(var1.get(0).getTime());
    }//end runIt

    public static void main(String[] args){
        new Q12().runIt();
    }//end main

} //end class Q12
//=====//

```

1378060513651

Table 4.103

Answer 12 (p. 1345)

4.3.2.3.13 Question 13

True or False: The code shown in Listing 7 (p. 1341) will compile and run successfully and produce the output shown in Figure 5 (p. 1341) .

Listing 7 - Question 13.

```

/*File Q13.java
*****/

import java.util.*;

public class Q13{
    ArrayList <Integer> var1 = new ArrayList<Integer>();

    void runIt(){

        var1.add(new Integer(1));
        var1.add(new Integer(2));
        var1.add(new Integer(3));

        //Get an iterator
        Iterator iter = var1.iterator();

        //Perform the iteration
        while(iter.hasNext()){
            System.out.println(iter.next().intValue());
        }//end while loop

    }//end runIt

    public static void main(String[] args){
        new Q13().runIt();
    }//end main

} //end class Q13
//=====//

```

- Listing 6 (p. 1340) . Question 12.
- Listing 7 (p. 1341) . Question 13.
- Listing 8 (p. 1344) . Answer 13.
- Listing 9 (p. 1346) . Answer 10.
- Listing 10 (p. 1347) . Answer 8.

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

4.3.2.6 Answers

4.3.2.6.1 Answer 13

False. This program produces the error shown in Figure 6 (p. 1345) below. You must qualify the iterator as shown in Listing 8 (p. 1344) to correct the error. If you don't qualify the iterator, the reference is retrieved from the list as type Object. The Object class neither defines nor inherits a method named intValue.

Listing 8 - Answer 13.

```

/*File A13.java
*****/

import java.util.*;

public class A13{
    ArrayList <Integer> var1 = new ArrayList<Integer>();

    void runIt(){

        var1.add(new Integer(1));
        var1.add(new Integer(2));
        var1.add(new Integer(3));

        //Get an iterator
        Iterator <Integer> iter = var1.iterator();

        //Perform the iteration
        while(iter.hasNext()){
            System.out.println(iter.next().intValue());
        }//end while loop

    }//end runIt

    public static void main(String[] args){
        new Q13().runIt();
    }//end main

} //end class A13
//=====//

```

Table 4.106

Figure 6 - Answer 13.
<pre> Q13.java:22: error: cannot find symbol System.out.println(iter.next().intValue()); ^ symbol: method intValue() location: class Object 1 error </pre>

Table 4.107

Back to Question 13 (p. 1340)

4.3.2.6.2 Answer 12

False. This program produces the compiler error shown in Figure 7 (p. 1345) below. This is the result of attempting to store an object's reference of type String in a collection reserved exclusively for references to objects of type Date.

Figure 7 - Answer 12.
<pre> Q12.java:13: error: no suitable method found for add(String) var1.add("abcd"); ^ method ArrayList.add(int,Date) is not applicable (actual and formal argument lists differ in length) method ArrayList.add(Date) is not applicable (actual argument String cannot be converted to Date by method invocation conversion) 1 error </pre>

Table 4.108

Back to Question 12 (p. 1340)

4.3.2.6.3 Answer 11

True. Updates made in Java v1.7 eliminated the requirement to insert the name of a type in those angle brackets in order to make the compiler happy.

Back to Question 11 (p. 1339)

4.3.2.6.4 Answer 10

One solution is to add the generic syntax shown in the class named A10 in Listing 9 (p. 1346) below. This will cause the program to compile and execute successfully producing an output similar to that shown in Figure 8 (p. 1346) below.

Listing 9 - Answer 10.

```

/*File A10.java
*****/

import java.util.*;

public class A10{

    ArrayList <Date> var1 = new ArrayList<Date>();

    void runIt(){
        var1.add(new Date());
        //Note the required cast in the following
        // statement.
        System.out.println(
            (var1.get(0)).getTime());

    }//runIt

    public static void main(String[] args){
        new A10().runIt();
    }//end main

} //end class A10
//=====//

```

Table 4.109**Figure 8 - Answer 10.**

```
1378058466149
```

Table 4.110

Back to Question 10 (p. 1338)

4.3.2.6.5 Answer 9

False: The program produces the runtime error shown in Figure 9 (p. 1347) below. The (Date) cast is applied to the contents of the element at index 1. However, that element contains a reference to an object of type String.

Figure 9 - Answer 9.

```
Exception in thread "main" java.lang.ClassCastException: java.lang.String cannot
be cast to java.util.Date
    at Q09.runIt(Q09.java:15)
    at Q09.main(Q09.java:22)
```

Table 4.111

Back to Question 9 (p. 1337)

4.3.2.6.6 Answer 8

The program must be updated to include the cast operator (Date) shown in Listing 10 (p. 1347) below.

Listing 10 - Answer 8.

```
    /*File Q08.java
    *****/

import java.util.*;

public class Q08{

    ArrayList var1 = new ArrayList();

    void runIt(){
        var1.add(new Date());
        //Note the required cast in the following
        // statement.
        System.out.println(
            ((Date)var1.get(0)).getTime());

    }//runIt

    public static void main(String[] args){
        new Q08().runIt();
    }//end main

} //end class Q08
//=====//
```

Table 4.112

Back to Question 8 (p. 1337)

4.3.2.6.7 Answer 7

False: This program produces the compiler error shown in Figure 10 (p. 1348) below.

Figure 10 - Answer 7.
<pre> Q07.java:17: error: cannot find symbol (var1.get(0)).getTime()); ~ symbol: method getTime() location: class Object Note: Q07.java uses unchecked or unsafe operations. Note: Recompile with -Xlint:unchecked for details. 1 error </pre>

Table 4.113

Back to Question 7 (p. 1336)

4.3.2.6.8 Answer 6

B. A warning

The compiler output is shown in Figure 11 (p. 1348) below:

Figure 11 - Answer 6.
<pre> Q02.java:13: warning: [unchecked] unchecked call to add(E) as a member of the raw type ArrayList var1.add(new Date()); ~ where E is a type-variable: E extends Object declared in class ArrayList 1 warning </pre>

Table 4.114

Back to Question 6 (p. 1336)

4.3.2.6.9 Answer 5

False. Two notes are displayed. However, the messages produced by the Java v1.7 compiler in this cases are neither error messages nor warnings. Instead they are simply notes. The notes provide instructions on how to recompile and get more information regarding a potential problem.

Back to Question 5 (p. 1335)

4.3.2.6.10 Answer 4

False. The tentacles of generics reach into many different areas of Java in very complex ways including:

- Generic methods
- Generic classes
- Raw types
- Wildcards
- Generics and inheritance

Back to Question 4 (p. 1335)

4.3.2.6.11 Answer 3

B. Compile-time type safety

Back to Question 3 (p. 1335)

4.3.2.6.12 Answer 2

False: An attempt to compile the program using the Java v1.7 compiler produces an output similar to that shown in Figure 12 (p. 1349) below.

Figure 12 - Answer 2.

Note: Q02.java uses unchecked or unsafe operations.
Note: Recompile with -Xlint:unchecked for details.

Table 4.115

Back to Question 2 (p. 1334)

4.3.2.6.13 Answer 1

False. The Collections framework was not new in Java v1.5. It was available long before version 1.5 was released.

Back to Question 1 (p. 1334)

4.3.2.7 Miscellaneous

This section contains a variety of miscellaneous information.

4.3.3.2 Preface

This module is one in a collection of modules on Java Generics designed for teaching *ITSE2317 - Java Programming (Intermediate)* at Austin Community College in Austin, TX.

This and future modules in this series will be based on the Generics (Updated) ⁸¹ section of The Java Tutorials ⁸² from Oracle. (*In the event that these links become broken, you should have no difficulty finding the Oracle material with an online search.*)

You will find the learning resources for this module on the Oracle site at:

- Generics (Updated) ⁸³
- Why Use Generics ⁸⁴
- Generic Types ⁸⁵
 - Raw Types ⁸⁶

This module contains review questions and answers keyed to the material in the above list.

Once you study that material, you should be able to answer the review questions in this module.

Once you complete your study of all the material on generics ⁸⁷, you should be able to answer the review questions at Questions and Exercises ⁸⁸ on the Oracle site.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

4.3.3.3 Questions

4.3.3.3.1 Question 1

True or False: Generics add stability to your code by making more of your bugs detectable at runtime.

Answer 1 (p. 1365)

4.3.3.3.2 Question 2

True or False: Generics enable *types* (classes and interfaces) to be parameters when defining classes, interfaces and methods.

Answer 2 (p. 1365)

4.3.3.3.3 Question 3

True or False: Type parameters provide a way for you to re-use the same code with different inputs. The inputs to type parameters are values.

Answer 3 (p. 1365)

4.3.3.3.4 Question 4

True or False: Code that uses generics provides the following benefits over non-generic code:

- Stronger type checks at compile time.
- Elimination of casts.
- Enabling programmers to implement generic algorithms.

Answer 4 (p. 1365)

⁸¹<http://docs.oracle.com/javase/tutorial/java/generics/>

⁸²<http://docs.oracle.com/javase/tutorial/index.html>

⁸³<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

⁸⁴<http://docs.oracle.com/javase/tutorial/java/generics/why.html>

⁸⁵<http://docs.oracle.com/javase/tutorial/java/generics/types.html>

⁸⁶<http://docs.oracle.com/javase/tutorial/java/generics/rawTypes.html>

⁸⁷<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

⁸⁸<http://docs.oracle.com/javase/tutorial/java/generics/QandE/generics-questions.html>

4.3.3.3.5 Question 5

True or False: A *generic type* is a generic class or interface that is parameterized over types.

Answer 5 (p. 1364)

4.3.3.3.6 Question 6

True or False: The code shown in Listing 1 (p. 1353) will compile and run successfully producing the output shown in Figure 1 (p. 1353) .

Listing 1 - Question 6.

```

/*File Q06.java
*****/
public class Q06{

    public static void main(String[] args){
        Box box = new Box();
        box.set(new Integer(5));
        System.out.println(
            ((Integer)(box.get())).intValue());
    }//end main
} //end class Q06

class Box{
    private Object object;

    public void set(Object object){
        this.object = object;
    } //end set

    public Object get(){
        return object;
    } //end get
} //end Box
//=====//

```

Table 4.116

Figure 1 - Question 6..

5

Table 4.117

Answer 6 (p. 1364)

4.3.3.3.7 Question 7

True or False: The code shown in Listing 2 (p. 1354) will compile and run successfully producing the output shown in Figure 2 (p. 1354) .

Listing 2 - Question 7.
<pre> /*File Q07.java ***** public class Q07{ public static void main(String[] args){ Box <Integer> box = new Box <Integer>(); box.set(new Integer(5)); System.out.println(box.get().intValue()); }//end main } //end class Q07 class Box{ private Object object; public void set(Object object){ this.object = object; } //end set public Object get(){ return object; } //end get } //end Box //=====// </pre>

Table 4.118

Figure 2 - Question 7.
5

Table 4.119

Answer 7 (p. 1364)

4.3.3.3.8 Question 8

Design and write a class named A08Box which, when combined with the class defined in Listing 3 (p. 1355) will compile, run, and produce the output shown in Figure 3 (p. 1355) .

Listing 3 - Question 8.

```

/*File Q08.java
*****/
public class Q08{

    public static void main(String[] args){
        A08Box <Integer> box = new A08Box <Integer>();
        box.set(new Integer(5));
        System.out.println(box.get().intValue());
    }//end main
} //end class Q08
//=====//

```

Table 4.120**Figure 3 - Question 8.**

5

Table 4.121

Answer 8 (p. 1363)

4.3.3.3.9 Question 9

True or False: The program with the "diamond" syntax shown in Listing 4 (p. 1356) will compile and run with no compiler complaints under Java v1.7, producing the output shown in Figure 4 (p. 1356) .

Listing 4 - Question 9.

```

/*File Q09.java
*****/
public class Q09{

    public static void main(String[] args){
        Box <> box = new Box <Integer>();
        box.set(new Integer(5));
        System.out.println(box.get().intValue());
    }//end main
} //end class Q09
//=====//
class Box<T>{
    private T t;

    public void set(T t){
        this.t = t;
    } //end set

    public T get(){
        return t;
    } //end get
} //end Box
//=====//

```

Table 4.122**Figure 4 - Question 9.**

5

Table 4.123

Answer 9 (p. 1363)

4.3.3.3.10 Question 10

True or False: The program with the "diamond" syntax shown in Listing 5 (p. 1357) will compile and run with no compiler complaints under Java v1.7, producing the output shown in Figure 5 (p. 1357) .

Listing 5 - Question 10.

```

/*File Q10.java
*****/
public class Q10{

    public static void main(String[] args){
        Box <Integer> box = new Box <>();
        box.set(new Integer(5));
        System.out.println(box.get().intValue());
    }//end main
} //end class Q10
//=====//
class Box<T>{
    private T t;

    public void set(T t){
        this.t = t;
    } //end set

    public T get(){
        return t;
    } //end get
} //end Box
//=====//

```

Table 4.124**Figure 5 - Question 10.**

5

Table 4.125

Answer 10 (p. 1363)

4.3.3.3.11 Question 11

Design and write a class named A11Box which, when used in conjunction with the code shown in Listing 6 (p. 1358) , will compile and run successfully producing the output shown in Figure 6 (p. 1358) .

Listing 6 - Question 11.

```

/*File Q11.java
*****/
public class Q11{

    public static void main(String[] args){
        A11Box <Integer> box =
            new A11Box <>(new Integer(5));
        System.out.println(box.get().intValue());
    }//end main
} //end class Q11
//=====//

```

Table 4.126**Figure 6 - Question 11.**

5

Table 4.127

Answer 11 (p. 1362)

4.3.3.3.12 Question 12

Design and write a class named A12Box which, when used in conjunction with the code shown in Listing 7 (p. 1359) , will compile and run successfully producing the output shown in Figure 7 (p. 1359) .

Listing 7 - Question 12.

```

/*File Q12.java
*****/
public class Q12{

    public static void main(String[] args){
        A12Box <String,Integer> boxA =
            new A12Box <>("abcde",new Integer(500));
        System.out.println(boxA.get1());
        System.out.println(boxA.get2());

        A12Box <Integer,String> boxB =
            new A12Box <>(new Integer(900),"fghijkl");
        System.out.println(boxB.get1());
        System.out.println(boxB.get2());
    }//end main
} //end class Q12
//=====//

```

Table 4.128**Figure 7 - Question 12.**

```

abcde
500
900
fghijkl

```

Table 4.129

Answer 12 (p. 1362)

4.3.3.3.13 Question 13

Given: When mixing legacy code with generic code, you may encounter messages similar to those shown in Figure 8 (p. 1359) .

Figure 8 - Question 13.

continued on next page

Note: Example.java uses unchecked or unsafe operations.
Note: Recompile with -Xlint:unchecked for details.

Table 4.130

True or False: In such cases, the term "unchecked" means that the compiler does not have enough type information to perform all type checks necessary to ensure type safety.

Answer 13 (p. 1362)

4.3.3.4 Figures

- Figure 1 (p. 1353) . Question 6.
- Figure 2 (p. 1354) . Question 7.
- Figure 3 (p. 1355) . Question 8.
- Figure 4 (p. 1356) . Question 9.
- Figure 5 (p. 1357) . Question 10.
- Figure 6 (p. 1358) . Question 11.

- Figure 8 (p. 1359) . Question 13.
- Figure 9 (p. 1363) . Answer 9.
- Figure 10 (p. 1364) . Answer 7.

4.3.3.5 Listings

- Listing 1 (p. 1353) . Question 6.
- Listing 2 (p. 1354) . Question 7.
- Listing 3 (p. 1355) . Question 8.
- Listing 4 (p. 1356) . Question 9.
- Listing 5 (p. 1357) . Question 10.
- Listing 6 (p. 1358) . Question 11.
- Listing 7 (p. 1359) . Question 12.
- Listing 8 (p. 1362) . Answer 12.
- Listing 9 (p. 1363) . Answer 11.
- Listing 10 (p. 1364) . Answer 8.

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

4.3.3.6 Answers

4.3.3.6.1 Answer 13

True.

Back to Question 13 (p. 1359)

4.3.3.6.2 Answer 12

One possible solution is provided in Listing 8 (p. 1362) below.

Listing 8 - Answer 12.

```

/*File A12Box.java
*****/
public class A12Box<T1,T2>{
    private T1 t1;
    private T2 t2;

    public A12Box(T1 t1,T2 t2){
        this.t1 = t1;
        this.t2 = t2;
    }//end constructor

    public T1 get1(){
        return t1;
    }//end get1

    public T2 get2(){
        return t2;
    }//end get2
} //end A12Box
//=====//

```

Table 4.131

Back to Question 12 (p. 1358)

4.3.3.6.3 Answer 11

One possible solution is provided in Listing 9 (p. 1363) below.

Listing 9 - Answer 11.

continued on next page

```

/*File A11Box.java
*****/
public class A11Box<T>{
    private T t;

    public A11Box(T t){
        this.t = t;
    }//end constructor

    public T get(){
        return t;
    }//end get
} //end A11Box
//=====//

```

Table 4.132

Back to Question 11 (p. 1357)

4.3.3.6.4 Answer 10

True.

Back to Question 10 (p. 1356)

4.3.3.6.5 Answer 9

False. This program produces the error message shown in Figure 9 (p. 1363) below.

Figure 9 - Answer 9.

```

Q09.java:8: error: illegal start of type
    Box <> box = new Box <Integer>();
        ^
1 error

```

Table 4.133

Back to Question 9 (p. 1355)

4.3.3.6.6 Answer 8

One possible solution is shown in Listing 10 (p. 1364) below.

Listing 10 - Answer 8.

```

/*File A08Box.java
*****
public class A08Box<T>{
    private T t;

    public void set(T t){
        this.t = t;
    }//end set

    public T get(){
        return t;
    }//end get
} //end A08Box
//=====//

```

Table 4.134

Back to Question 8 (p. 1354)

4.3.3.6.7 Answer 7

False. This program produces the compiler errors shown in Figure 10 (p. 1364) below.

Figure 10 - Answer 7.

```

Q07.java:8: error: type Box does not take parameters
    Box <Integer> box = new Box <Integer>();
    ^
Q07.java:8: error: type Box does not take parameters
    Box <Integer> box = new Box <Integer>();
    ^
2 errors

```

⁹³<http://docs.oracle.com/javase/tutorial/index.html>

⁹⁴<http://docs.oracle.com/javase/tutorial/java/generics/methods.html>

This module contains review questions and answers keyed to the material in the above document.

Once you study that material, you should be able to answer the review questions in this module.

Once you complete your study of all the material on generics ⁹⁵, you should be able to answer the review questions at Questions and Exercises ⁹⁶ on the Oracle site.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

4.3.4.3 Questions

4.3.4.3.1 Question 1 .

True or False: Generic methods are methods that introduce their own type parameters.

Answer 1 (p. 1375)

4.3.4.3.2 Question 2

True or False: Defining a generic method is similar to declaring a generic type. The type parameter's scope is limited to the class in which it is declared.

Answer 2 (p. 1375)

4.3.4.3.3 Question 3

True or False: Generic methods may be either static or non-static.

Answer 3 (p. 1375)

4.3.4.3.4 Question 4

True or False: Generic class constructors are not allowed.

Answer 4 (p. 1375)

4.3.4.3.5 Question 5

Design and write a class named A05Foo which, when combined with the class defined in Listing 1 (p. 1368) will compile, run, and produce the output shown in Figure 1 (p. 1368) .

⁹⁵<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

```

Table 4.139

Answer 6 (p. 1373)

4.3.4.3.7 Question 7

Design and write a class named A07Foo which, when combined with the class defined in Listing 3 (p. 1370) will compile, run, and produce the output shown in Figure 3 (p. 1370) .

Listing 3 - Question 7.

```

/*File Q07.java
*****
public class Q07{

    public static void main(String[] args){
        A07Foo <Integer,String>fooA =
            new A07Foo<>(" ijkl");
        fooA.set(new Integer(-300));
        System.out.println(
            fooA.cat("abcd "," efgh "));
        System.out.println(
            fooA.cat("abcd ",new Integer(500)));
        System.out.println(
            fooA.cat(new Integer(500)," abcd "));
    }//end main
} //end class Q07
//=====//

```

Table 4.140**Figure 3 - Question 7.**

```

abcd efgh -300 ijkl
abcd 500-300 ijkl
500 abcd -300 ijkl

```

Table 4.141

Answer 7 (p. 1372)

4.3.4.3.8 Question 8

True or False: The syntax for a generic method includes a type parameter, inside angle brackets, and appears after the method's return type

Answer 8 (p. 1372)

4.3.4.4 Figures

- Figure 1 (p. 1368) . Question 5.
- Figure 2 (p. 1369) . Question 6.
- Figure 3 (p. 1370) . Question 7.

4.3.4.5 Listings

- Listing 1 (p. 1368) . Question 5.
- Listing 2 (p. 1369) . Question 6.
- Listing 3 (p. 1370) . Question 7.
- Listing 4 (p. 1373) . Answer 7.
- Listing 5 (p. 1374) . Answer 6.
- Listing 6 (p. 1374) . Answer 5.

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

4.3.4.6 Answers

4.3.4.6.1 Answer 8

False. The statement should read:

"The syntax for a generic method includes a type parameter, inside angle brackets, and appears **before** the method's return type"

Back to Question 8 (p. 1370)

4.3.4.6.2 Answer 7

One possible solution is provided in Listing 4 (p. 1373) below.

Listing 4 - Answer 7.

```
/*File A07Foo.java
*****/
//A generic class
public class A07Foo<T3,T4>{
    private T3 tC;
    private T4 tD;

    //constructor
    public A07Foo(T4 tD){
        this.tD = tD;
    }//end constructor

    //A set method
    public void set(T3 tC){
        this.tC = tC;
    }//end cat

    //A generic concatenation method
    public <T1,T2> String cat(T1 tA,T2 tB){
        return tA.toString() + tB.toString()
            + tC.toString() + tD.toString();
    }//end cat

} //end A07Foo
//=====//
```

Table 4.142

Back to Question 7 (p. 1369)

4.3.4.6.3 Answer 6

One possible solution is provided in Listing 5 (p. 1374) below.

Listing 5 - Answer 6.

```

/*File A06Foo.java
*****/
public class A06Foo<T3>{
    private T3 tC;

    //A set method
    public void set(T3 tC){
        this.tC = tC;
    }//end cat

    //A generic concatenation method
    public <T1,T2> String cat(T1 tA,T2 tB){
        return tA.toString() + tB.toString()
                               + tC.toString();
    }//end cat
} //end A06Foo
//=====//

```

Table 4.143

Back to Question 6 (p. 1368)

4.3.4.6.4 Answer 5

One possible solution is provided in Listing 6 (p. 1374) below.

Listing 6 - Answer 5.

```

/*File A05Foo.java
*****/
public class A05Foo{
    //A generic concatenation method
    public <T1,T2> String cat(T1 tA,T2 tB){
        return tA.toString() + tB.toString();
    }//end cat
} //end A05Foo
//=====//

```

Table 4.144

Back to Question 5 (p. 1367)

4.3.4.6.5 Answer 4

False. Generic class constructors **are** allowed.

Back to Question 4 (p. 1367)

4.3.4.6.6 Answer 3

True.

Back to Question 3 (p. 1367)

4.3.4.6.7 Answer 2

False. The statement should read as follows:

"Defining a generic method is similar to declaring a generic type, but the type parameter's scope is limited to the **method** where it is declared."

Back to Question 2 (p. 1367)

4.3.4.6.8 Answer 1

True.

Back to Question 1 (p. 1367)

4.3.4.7 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

4.3.5.2 Preface

This module is one in a collection of modules on Java Generics designed for teaching *ITSE2317 - Java Programming (Intermediate)* at Austin Community College in Austin, TX.

This and future modules in this series will be based on the Generics (Updated) ¹⁰⁰ section of The Java Tutorials ¹⁰¹ from Oracle. (*In the event that these links become broken, you should have no difficulty finding the Oracle material with an online search.*)

You will find the learning resources for this module on the Oracle site at:

⁹⁷This content is available online at <<http://cnx.org/content/m47819/1.5/>>.

⁹⁸<http://cnx.org/contents/Rl23r3Lw>

⁹⁹http://cnx.org/contents/-2RmHFs_

¹⁰⁰<http://docs.oracle.com/javase/tutorial/java/generics/>

¹⁰¹<http://docs.oracle.com/javase/tutorial/index.html>

- Bounded Type Parameters ¹⁰²
 - Generic Methods and Bounded Type Parameters ¹⁰³

This module contains review questions and answers keyed to the material in the above listed documents.

Once you study that material, you should be able to answer the review questions in this module.

Once you complete your study of all the material on generics ¹⁰⁴, you should be able to answer the review questions at Questions and Exercises ¹⁰⁵ on the Oracle site.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

4.3.5.3 Questions

4.3.5.3.1 Question 1 .

True or False: Bounded type parameters are used to restrict the types that can be used as arguments in a parameterized type.

Answer 1 (p. 1390)

4.3.5.3.2 Question 2

True or False: To declare a bounded type parameter, list the type parameter's name, followed by the **extends** or **implements** keyword, followed by its upper bound class or interface.

Answer 2 (p. 1390)

4.3.5.3.3 Question 3

True or False: A type parameter can have multiple bounds as shown in Figure 1 (p. 1377) .

Figure 1 - Question 3.
<code><T extends B1 & B2 & B3></code>

Table 4.145

Answer 3 (p. 1390)

4.3.5.3.4 Question 4

True or False: The code shown in Listing 1 (p. 1377) will compile and run successfully producing the output shown in Figure 2 (p. 1378) .

Listing 1 - Question 4.

- Listing 9 (p. 1389) . Answer 5.

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

4.3.5.6 Answers**4.3.5.6.1 Answer 10**

False. This is an unsuccessful call to generic method with specified upper-bound of Object. The incoming reference is received as type Object and must be downcast to at least Frame to call the method named getTitle. The incoming parameter is received as the type of the specified upper-bound. This results in the compiler error shown in Figure 9 (p. 1387) .

Figure 9 - Answer 10.
<pre> Q10.java:36: error: cannot find symbol System.out.println(ref.getTitle()); ^ symbol: method getTitle() location: variable ref of type T where T is a type-variable: T extends Object declared in method <T>runIt(T) 1 error </pre>

Table 4.160

Back to Question 10 (p. 1384)

4.3.5.6.2 Answer 9

False. This is an unsuccessful call to generic method with default upper-bound of Object. The incoming reference is received as type Object and must be downcast to at least Frame to call the method named getTitle. The incoming parameter is received as the type of the specified upper-bound which is Object by default. This results in the compiler error shown in Figure 10 (p. 1387) .

Figure 10 - Answer 9.
<pre> Q09.java:36: error: cannot find symbol System.out.println(ref.getTitle()); ^ symbol: method getTitle() location: variable ref of type T where T is a type-variable: T extends Object declared in method <T>runIt(T) 1 error </pre>

Table 4.161

Back to Question 9 (p. 1383)

4.3.5.6.3 Answer 8

False. This is an unsuccessful call to a generic method where the type of the object passed to the method is above the upper bound on the specified generic type for the method. An attempt to compile the program results in the error shown in Figure 11 (p. 1388) below.

Figure 11 - Answer 8.
<pre> Q08.java:25: error: method runIt in class Foo cannot be applied to given types; aFoo.runIt(aFrame); ^ required: T found: Frame reason: inferred type does not conform to declared bound(s) inferred: Frame bound(s): JFrame where T is a type-variable: T extends JFrame declared in method <T>runIt(T) 1 error </pre>

Table 4.162

Back to Question 8 (p. 1382)

4.3.5.6.4 Answer 7

True. This is a successful call to a generic method where the generic type for the method is above (*in the inheritance hierarchy*) the type of object passed as a parameter.

Back to Question 7 (p. 1380)

4.3.5.6.5 Answer 6

One possible solution is shown in Listing 8 (p. 1389) below.

Listing 8 - Answer 6.

```

/*File A06Foo.java
*****/
import java.awt.*;

public class A06Foo<T extends Component>{
    private T param;

    public A06Foo(T param){
        this.param = param;
    }//end constructor

    public void runIt(){
        System.out.println("Object instantiated.");
        System.out.println(param.getClass());
    }//end runIt
} //end A06Foo
//=====//

```

Table 4.163

Back to Question 6 (p. 1379)

4.3.5.6.6 Answer 5

One possible solution is shown in Listing 9 (p. 1389) below where **T extends Component** . However, causing T to extend Window, Container, Component, or Object would all be valid solutions. The upper bound for T must be at or above the type being passed as a type parameter in the inheritance hierarchy.

Listing 9 - Answer 5.

```

/*File A05Foo.java
*****/
import java.awt.*;

public class A05Foo<T extends Component>{
    public void runIt(){
        System.out.println("Object instantiated.");
    }//end runIt
} //end A05Foo
//=====//

```

Table 4.164

Back to Question 5 (p. 1378)

4.3.5.6.7 Answer 4

False. This program produces the compiler error shown in Figure 12 (p. 1390) below. The problem is that the upper bound for the type parameter in the class named Foo (Frame) is below the type passed as a parameter (Window) in the attempt to instantiate an object of the class named Foo.

Figure 12 - Answer 4.

```
Q04.java:20: error: type argument Window is not within bounds
of type-variable T
    Foo <Window> aFoo = new Foo <>();
        ^
    where T is a type-variable:
      T extends Frame declared in class Foo
Q04.java:20: error: cannot infer type arguments for Foo<>;
    Foo <Window> aFoo = new Foo <>();
        ^
    reason: no instance(s) of type variable(s) T exist so that
    Foo<T> conforms to
    Foo<Window>
    where T is a type-variable:
      T extends Frame declared in class Foo
2 errors
```

Table 4.165

Back to Question 4 (p. 1377)

4.3.5.6.8 Answer 3

True. A type variable with multiple bounds is a subtype of all the types listed in the bound. If one of the bounds is a class, it must be specified first.

Back to Question 3 (p. 1377)

4.3.5.6.9 Answer 2

False. The correct statement is:

"To declare a bounded type parameter, list the type parameter's name, followed by the **extends** keyword, followed by its upper bound. Note that, in this context, extends is used in a general sense to mean either "extends" (as in classes) or "implements" (as in interfaces)."

Back to Question 2 (p. 1377)

4.3.5.6.10 Answer 1

True. There may be times when you want to restrict the types that can be used as type arguments in a parameterized type. For example, a method that operates on numbers might only want to accept instances of Number or its subclasses. This is what bounded type parameters are for.

Back to Question 1 (p. 1377)

4.3.5.7 Miscellaneous

This section contains a variety of miscellaneous information.

4.3.6.2 Preface

This module is one in a collection of modules on Java Generics designed for teaching *ITSE2317 - Java Programming (Intermediate)* at Austin Community College in Austin, TX.

This and future modules in this series will be based on the Generics (Updated) ¹⁰⁹ section of The Java Tutorials ¹¹⁰ from Oracle. (*In the event that these links become broken, you should have no difficulty finding the Oracle material with an online search.*)

You will find the learning resources for this module on the Oracle site at Generics, Inheritance, and Subtypes ¹¹¹.

This module contains review questions and answers keyed to the material in that document.

Once you study that material, you should be able to answer the review questions in this module.

Once you complete your study of all the material on generics ¹¹², you should be able to answer the review questions at Questions and Exercises ¹¹³ on the Oracle site.

4.3.6.3 Questions

4.3.6.3.1 Question 1 .

True or False: The code shown in Listing 1 (p. 1393) will compile and run successfully producing the output shown in Figure 1 (p. 1394) .

Listing 1 - Question 1.

```

/*File Q01.java
*****
/*
Integer and Double are both subclasses of
Number. Both classes define a method named
doubleValue that returns the encapsulated
numeric value as type double.
*/
public class Q01{

    public static void main(String[] args){
        Foo <Integer> iFoo = new Foo <Integer>(15);
        System.out.println(iFoo.get().doubleValue());

        Foo <Double> dFoo = new Foo <Double>(1.0/3);
        System.out.println(dFoo.get().doubleValue());

    }//end main
} //end class Q01
//=====//

class Foo<T extends Number>{
    private T obj;

    public Foo(T obj){
        this.obj = obj;
    } //end constructor

    public T get(){
        return obj;
    } //end get
} //end Foo
//=====//

```

Table 4.166

Table 4.167

Answer 1 (p. 1406)

4.3.6.3.2 Question 2

True or False: The code shown in Listing 2 (p. 1395) will compile and run successfully producing the output shown in Figure 2 (p. 1396) .

Listing 2 - Question 2.

```

/*File Q02.java
*****
import java.awt.Frame;
import javax.swing.JInternalFrame;
import java.awt.Container;
/*
Frame and JInternalFrame are both subclasses of
Container. Both classes define a constructor
that accepts a String as a title. Both classes
define a method named getTitle that returns the
title string.
*/
public class Q02{

    public static void main(String[] args){
        Foo <Frame> fFoo =
            new Foo <Frame>(
                new Frame("Frame title"));
        System.out.println(fFoo.get().getTitle());

        Foo <JInternalFrame> jFoo =
            new Foo <JInternalFrame>(
                new JInternalFrame(
                    "JInternalFrame title"));
        System.out.println(jFoo.get().getTitle());

    }//end main
} //end class Q02
//=====//

class Foo<T extends Container>{
    private T obj;

    public Foo(T obj){
        this.obj = obj;
    } //end constructor

    public T get(){
        return obj;
    } //end get
} //end Foo
//=====//

```

Table 4.168

Table 4.169

Answer 2 (p. 1406)

4.3.6.3.3 Question 3

True or False: The code shown in Listing 3 (p. 1397) will compile and run successfully producing the output shown in Figure 3 (p. 1398) .

Listing 3 - Question 3.

```

/*File Q03.java
*****/
public class Q03{
/*
Integer and Double are both subclasses of
Number. Both classes define a method named
doubleValue that returns the encapsulated
numeric value as type double.
*/
    public static void main(String[] args){
        Foo <Integer> iFoo = new Foo <Integer>(15);
        System.out.println(iFoo.get().doubleValue());

        Foo <Double> dFoo = new Foo <Double>(1.0/3);
        System.out.println(dFoo.get().doubleValue());

        displayClassI(iFoo);
        displayClassD(dFoo);
    }//end main
    //-----//

    static void displayClassI(Foo<Integer> obj){
        System.out.println(obj.getClass());
    }//end displayClassI
    //-----//

    static void displayClassD(Foo<Double> obj){
        System.out.println(obj.getClass());
    }//end displayClassD
} //end class Q03
//=====//

class Foo<T extends Number>{
    private T obj;

    public Foo(T obj){
        this.obj = obj;
    }//end constructor

    public T get(){
        return obj;
    }//end get
} //end Foo
//=====//

```

4.3.6.3.4 Question 4

True or False: The code shown in Listing 4 (p. 1398) will compile and run successfully producing the output shown in Figure 4 (p. 1399) .

Listing 4 - Question 4.

```

/*File Q04.java
*****
import java.awt.Frame;
import javax.swing.JFrame;
import java.awt.Container;
/*
Frame and JFrame are both subclasses of
Container. Both classes define a constructor
that accepts a String as a title. Both classes
define a method named getTitle that returns the
title string.
*/
public class Q04{

    public static void main(String[] args){
        Foo <Frame> fFoo =
            new Foo <Frame>(
                new Frame("Frame title"));
        System.out.println(fFoo.get().getTitle());

        Foo <JFrame> jFoo =
            new Foo <JFrame>(
                new JFrame(
                    "JFrame title"));
        System.out.println(jFoo.get().getTitle());

        displayClassF(fFoo);
        displayClassJ(jFoo);
    }//end main
    //-----//

    static void displayClassF(Foo<Frame> obj){

```

```

    System.out.println(obj.getClass());
} //end displayClassF
//-----//

static void displayClassJ(
    Foo<JInternalFrame> obj){
    System.out.println(obj.getClass());
} //end displayClassJ
} //end class Q04
//=====//

class Foo<T extends Container>{
    private T obj;

    public Foo(T obj){
        this.obj = obj;
    } //end constructor

    public T get(){
        return obj;
    } //end get
} //end Foo
//=====//

```

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

4.3.6.6 Answers

4.3.6.6.1 Answer 6

False. This program illustrates that you cannot pass an object of a parameterized class to a method that is designed to accept an incoming parameter of that class with a specific type of parameter that is a superclass of the actual type of parameter. An attempt to compile the program results in the error shown in Figure 7 (p. 1405) .

Figure 7 - Answer 6.

```
Q06.java:29: error: method displayClass in class Q06 cannot be
applied to given types;
    displayClass(fFoo);
    ^
   required: Foo<Container>
   found:    Foo<Frame>
   reason:   actual argument Foo<Frame> cannot be converted to
             Foo<Container> by method invocation conversion
1 error
```

Table 4.177

Back to Question 6 (p. 1401)

4.3.6.6.2 Answer 5

False. This program illustrates that you cannot pass an object of a parameterized class to a method that is designed to accept an incoming parameter of that class with a specific type of parameter that is a superclass of the actual type of parameter. An attempt to compile the program results in the error shown in Figure 8 (p. 1405) .

Figure 8 - Answer 5.

```
Q05.java:23: error: method displayClass in class Q05 cannot be
applied to given types;
    displayClass(iFoo);
    ^
   required: Foo<Number>
   found:    Foo<Integer>
   reason:   actual argument Foo<Integer> cannot be converted to
             Foo<Number> by method invocation conversion
1 error
```

Table 4.178

Back to Question 5 (p. 1399)

4.3.6.6.3 Answer 4

True. This program illustrates passing an object of a parameterized class to a method that is designed to accept an incoming parameter of that class with a specific type of parameter.

Back to Question 4 (p. 1398)

4.3.6.6.4 Answer 3

True. This program illustrates passing an object of a parameterized class to a method that is designed to accept an incoming parameter of that class with a specific type of parameter.

Back to Question 3 (p. 1396)

4.3.6.6.5 Answer 2

True. This program illustrates the successful use of bounded type parameters.

Back to Question 2 (p. 1394)

4.3.6.6.6 Answer 1

True. This program illustrates the successful use of bounded type parameters. It also illustrates the use of autoboxing to encapsulate primitive types `int` and `double` into objects of the wrapper classes `Integer` and `Double`.

Back to Question 1 (p. 1393)

4.3.6.7 Miscellaneous

This section contains a variety of miscellaneous information.

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

4.3.7.6 Answers**4.3.7.6.1 Answer 6**

False. This program illustrates incorrect use of the diamond for type inference and will not compile. In Java SE 7 and later, you can replace the type arguments required to invoke the constructor of a generic class with an empty set of matching angle brackets as long as the compiler can determine, or infer, the type arguments from the context. This pair of angle brackets, is informally called the diamond. However, in this case, the diamond is in the wrong location. This results in the errors shown in Figure 7 (p. 1418) .

Figure 7 - Answer 6.
<pre> Q06.java:18: error: illegal start of type Foo <> varA = ^ Q06.java:23: error: illegal start of type Foo <> varB = ^ 2 errors </pre>

Table 4.191

Back to Question 6 (p. 1414)

4.3.7.6.2 Answer 5

True. This program illustrates type inference. In Java SE 7 and later, you can replace the type arguments required to invoke the constructor of a generic class with an empty set of matching angle brackets as long as the compiler can determine, or infer, the type arguments from the context. This pair of angle brackets, is informally called the diamond.

Note that the Foo constructor requires two parameters and the types of those parameters are specified inside the angle brackets.

Also note that the order of the types of the two parameters is swapped between the instantiation of the first and second objects. The program also illustrates autoboxing.

Back to Question 5 (p. 1412)

4.3.7.6.3 Answer 4

True. This program illustrates generics without any obvious type inference. This is the style of programming that would have been used prior to the release of Java SE 7.

Note that the Foo constructor requires two parameters and the types of those parameters are specified inside the angle brackets.

Also note that the order of the types of the two parameters is swapped between the instantiation of the first and second objects. The program also illustrates autoboxing.

Back to Question 4 (p. 1410)

4.3.7.6.4 Answer 3

False. This program illustrates incorrect use of the diamond for type inference and will not compile. In Java SE 7 and later, you can replace the type arguments required to invoke the constructor of a generic class with

an empty set of matching angle brackets as long as the compiler can determine, or infer, the type arguments from the context. This pair of angle brackets, is informally called the diamond. However, in this case, the diamond is in the wrong location. Therefore, the program produces the error shown in Figure 8 (p. 1419) .

<p>Figure 8 - Answer 3.</p> <pre> Q03.java:26: error: illegal start of type Foo <> var = new Foo <Window>(); ^ 1 error </pre>
--

Table 4.192

[Back to Question 3 \(p. 1409\)](#)

4.3.7.6.5 Answer 2

True. This program illustrates bounded parameters along with type inference. In Java SE 7 and later, you can replace the type arguments required to invoke the constructor of a generic class with an empty set of matching angle brackets as long as the compiler can determine, or infer, the type arguments from the context. This pair of angle brackets, is informally called the diamond.

[Back to Question 2 \(p. 1409\)](#)

4.3.7.6.6 Answer 1

True. This program illustrates generics with bounded parameters but without any obvious type inference. This is the style of programming that would have been used prior to the release of Java SE 7.

[Back to Question 1 \(p. 1408\)](#)

4.3.7.7 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

4.3.8.2 Preface

This module is one in a collection of modules on Java Generics designed for teaching *ITSE2317 - Java Programming (Intermediate)* at Austin Community College in Austin, TX.

This and future modules in this series will be based on the Generics (Updated) ¹²⁵ section of The Java Tutorials ¹²⁶ from Oracle. (*In the event that these links become broken, you should have no difficulty finding the Oracle material with an online search.*)

You will find the learning resources for this module on the Oracle site at Wildcards ¹²⁷ .

This module contains review questions and answers keyed to the material in Wildcards ¹²⁸ .

Once you study that material, you should be able to answer the review questions in this module.

This is the final module in this series. This course does not cover the following topics:

- Type Erasure ¹²⁹

¹²²This content is available online at <<http://cnx.org/content/m47836/1.5/>>.

¹²³<http://cnx.org/contents/Rl23r3Lw>

¹²⁴http://cnx.org/contents/-2RmHFs_

¹²⁵<http://docs.oracle.com/javase/tutorial/java/generics/>

¹²⁶<http://docs.oracle.com/javase/tutorial/index.html>

¹²⁷<http://docs.oracle.com/javase/tutorial/java/generics/wildcards.html>

¹²⁸<http://docs.oracle.com/javase/tutorial/java/generics/wildcards.html>

¹²⁹<http://docs.oracle.com/javase/tutorial/java/generics/erasure.html>

- Restrictions on Generics ¹³⁰

However, once you complete your study of all the material on generics ¹³¹, (including the two topics listed above), you should be able to answer the review questions at Questions and Exercises ¹³² on the Oracle site.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

4.3.8.3 Questions

4.3.8.3.1 Question 1 .

True or False: The code shown in Listing 1 (p. 1422) will compile and run successfully producing the output shown in Figure 1 (p. 1423) .

Listing 1 - Question 1.

```

/*File Q01.java
*****/
import java.util.ArrayList;
import java.awt.Button;
import java.awt.Label;
import java.awt.Component;

public class Q01{
/*
Given:
Button and Label are subclasses of the Component
class.
The getClass method is defined in the Object
class. When called on a reference to an object,
the method returns the name of the class from
which the object was instantiated.
*/

public static void main(String[] args){
//Create and populate a list designed to
// store references to objects of type Button
// and display its contents.
ArrayList <Button> listA = new ArrayList<>();
listA.add(new Button("Button01"));
listA.add(new Button("Button02"));
display(listA);
System.out.println("");;//blank line

//Create and populate a list designed to
// store references to objects of type Label
// and display its contents.
ArrayList <Label> listB = new ArrayList<>();

```

¹³⁰<http://docs.oracle.com/javase/tutorial/java/generics/restrictions.html>

¹³¹<http://docs.oracle.com/javase/tutorial/java/generics/index.html>

¹³²<http://docs.oracle.com/javase/tutorial/java/generics/QandE/generics-questions.html>

```

    listB.add(new Label("Label01"));
    listB.add(new Label("Label02"));
    display(listB);
} //end main
//-----//

static void display(ArrayList<Component> list){
    for(Component n : list){
        System.out.println(n.getClass());
        if(n instanceof Button){
            System.out.println(
                ((Button)n).getLabel());
        }else if(n instanceof Label) {
            System.out.println(((Label)n).getText());
        } //end else
    } //end for loop
} //end display
} //end class Q01

```

4.3.8.6 Answers

4.3.8.6.1 Answer 6

False. This program attempts to illustrate the use of a lower bounded wildcard to define a generic method that will accept an incoming reference to an object of a generic class where the parameter type for the object is equal to or above the type of the wildcard in the inheritance hierarchy. The lower bounded wildcard type for the display method is `Frame`. Therefore, the display method will accept references to `ArrayList` objects for parameter types `Frame`, `Window`, `Container`, `Component`, or `Object`, but it will not accept a reference to an `ArrayList` object for parameter type `JFrame`. Therefore, the program will not compile, resulting in the error shown in Figure 7 (p. 1433) .

Figure 7 - Answer 6.
<pre> Q06.java:56: error: method display in class Q06 cannot be applied to given types; display(listC); ~ required: ArrayList<? super Frame> found: ArrayList<JFrame> reason: actual argument ArrayList<JFrame> cannot be converted to ArrayList<? super Frame> by method invocation conversion 1 error </pre>

Table 4.199

Back to Question 6 (p. 1429)

4.3.8.6.2 Answer 5

True. This program illustrates the use of a lower bounded wildcard to define a generic method that will accept an incoming reference to an object of a generic class where the parameter type for the object is equal to or above the type of the wildcard in the inheritance hierarchy. The lower bounded wildcard type for the display method is `JFrame`. Therefore, the display method will accept references to `ArrayList` objects for parameter types `JFrame`, `Frame`, `Window`, `Container`, `Component`, or `Object`

Back to Question 5 (p. 1428)

4.3.8.6.3 Answer 4

False. This program illustrates the fact that a parameter of type `Object` is not the same as an unbounded wildcard parameter. The program refuses to compile and produces the errors shown in Figure 8 (p. 1434) .

Figure 8 - Answer 4.
<i>continued on next page</i>

```

Q04.java:31: error: method display in class Q04 cannot be applied
to given types;
    display(listA);
    ^
    required: ArrayList<Object>
    found:    ArrayList<Button>
    reason:  actual argument ArrayList<Button> cannot be converted to
    ArrayList<Object> by method invocation conversion

Q04.java:40: error: method display in class Q04 cannot be applied
to given types;
    display(listB);
    ^
    required: ArrayList<Object>
    found:    ArrayList<Label>
    reason:  actual argument ArrayList<Label> cannot be converted to
    ArrayList<Object> by method invocation conversion
2 errors

```

Table 4.200

Back to Question 4 (p. 1426)

4.3.8.6.4 Answer 3

True. This program illustrates two scenarios where an unbounded wildcard is a useful approach:

1. When you are writing a method that can be implemented using functionality provided in the Object class. The getClass method that is called in the display method is defined in the Object class.
2. When the code in a generic method doesn't depend on the type parameter. An if-else statement along with specific casts is used in the display method to isolate the calls to the getText and getLabel methods from the type parameter.

Back to Question 3 (p. 1425)

4.3.8.6.5 Answer 2

True. This program illustrates the use of upper bounded wildcards. The method named display will accept and process a reference to an ArrayList object whose element types are Component or any subclass of Component. Methods that are defined in or inherited into the Component class can be called on the elements with no requirement for a cast. Methods that are not defined in or inherited into the Component class but are defined in the element classes can be called on the elements after casting to the element type.

Back to Question 2 (p. 1423)

4.3.8.6.6 Answer 1

False. This program will not compile. The method named display will only accept and process a reference to an ArrayList object whose element are of type Component. ArrayList objects whose element types are subclasses of Component do not satisfy that requirement. An attempt to compile the program produces the errors shown in Figure 9 (p. 1436) .

Figure 9 - Answer 1.

```

Q01.java:34: error: method display in class Q01
cannot be applied to given types;
    display(listA);
    ^
   required: ArrayList<Component>
   found:    ArrayList<Button>
   reason:  actual argument ArrayList<Button> cannot be converted to
           ArrayList<Component> by method invocation conversion

Q01.java:43: error: method display in class Q01 cannot be applied
to given types;
    display(listB);
    ^
   required: ArrayList<Component>
   found:    ArrayList<Label>
   reason:  actual argument ArrayList<Label> cannot be converted to
           ArrayList<Component> by method invocation conversion
2 errors

```

4.4 Event Handling

4.4.1 Jy0035: Java OOP: Preface to Event Handling¹³³

Revised: Thu May 12 10:35:00 CDT 2016

This page is included in the following Books:

- *ITSE2317 - Java Programming (Intermediate)* ¹³⁴
- *Object-Oriented Programming (OOP) with Java* ¹³⁵

4.4.1.1 Additional material

While most of the material required for success in the **Event Handling** portion of this course is contained in this book, other important material is contained in the section titled **Essence of OOP** in the book for the prerequisite course, ITSE 2321 - Object-Oriented Programming (Java) ¹³⁶.

In addition, the following material in the **Essence of OOP** section of this book is particularly germane to the **Event Handling** portion of this course:

- Javal636 Java OOP: Member Classes
- Javal638 Java OOP: Local Classes
- Javal640 Java OOP: Anonymous Classes

*(Note in particular that the page titled **Java1640 Java OOP: Anonymous Classes** contains quite a lot of material on event handling in addition to the material on anonymous classes. You will need to understand the material on anonymous classes as well as the material on event handling to succeed in the **Event Handling** portion of this course.)*

4.4.1.2 Miscellaneous

This section contains a variety of miscellaneous information.

4.4.2 Java Event Handling Basics

4.4.2.1 Java0073 Java OOP The AWT and Swing, A Preview¹³⁷

Revised: Thu May 12 10:07:20 CDT 2016

This page is included in the following Books:

- *ITSE2317 - Java Programming (Intermediate)* ¹³⁸
- *Object-Oriented Programming (OOP) with Java* ¹³⁹

4.4.2.1.1 Table of Contents

- Preface (p. 1438)
- Discussion (p. 1438)
- What's next? (p. 1440)
- Miscellaneous (p. 1440)

4.4.2.1.2 Preface

This module is part of a collection of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

(Editor's note: As you will see when you read this module, the original version was written about eighteen years ago. However, despite numerous improvements that have occurred in Java since then, most of what was true on this topic in 1998 is still true in 2012. A wise man once said, "If it ain't broke, don't fix it.")

*One of the changes that you will see in subsequent modules is that the name of the package that contains the **Swing** classes has been changed to **javax.swing** .)*

4.4.2.1.3 Discussion

This module provides a very brief preview of some of what you can expect to find in subsequent modules regarding the Abstract Windows Toolkit (**AWT**) and the **Swing** component set.

The user interface of a modern computer program often involves techniques to activate many of the human senses. We use *icons, text boxes, images, sound, boardroom graphics, etc.*

We weren't too concerned with these aspects of programming in the prerequisite course (*ITSE 2321*) because there was a lot that you needed to learn to prepare yourself for understanding material of this sort. That is about to change.

Much of the actual programming that you will do with Java will involve those aspects of the interface that we commonly refer to as the **Graphical User Interface (GUI)** .

As of 5/10/98, there are two primary packages that are used for **GUI** programming under JDK 1.1.6:

1. java. **awt** .*
2. com.sun.java. **swing** .*

There are, of course, numerous other packages that are used in support of these two packages.

The **AWT** material was made available to Java programmers early in the life of Java. This was the original material that was used to create graphical user interfaces. Major improvements to the **AWT** were introduced with the release of JDK 1.1.

¹³⁷This content is available online at <<http://cnx.org/content/m44331/1.5/>>.

¹³⁸<http://cnx.org/contents/Rl23r3Lw>

¹³⁹http://cnx.org/contents/-2RmHFs_

The **Swing** components became available in released form for use with JDK 1.1 around the beginning of 1998. These components added significantly to the ability of the programmer to create GUIs, both in terms of functionality and cosmetics.

The capability and cosmetics of the **AWT** were very limited but **Swing** made GUI programming in Java competitive in the real world. A Java programmer no longer need apologize for the quality of the GUIs that she can create.

We expect that these two packages may become more integrated (causing changes in your **import** directives) with the release of JDK 1.2, (*probably sometime in 1998*) but hopefully the concepts involved won't be greatly different.

As of 3/5/97, there were more than fifty classes defined in package **java.awt** . We will discuss some of the more important **AWT** classes in subsequent modules.

As of 5/10/98, the *com.sun.java.swing* package contains more than 75 classes and about 20 interfaces. You might expect, therefore, that learning to use this material effectively won't be a trivial task.

It is very important to understand that **Swing** is an extension of, and not a replacement for the **AWT** . While it is true that there is some overlap (*for example a **Swing JButton** component might be viewed as an improved functional replacement for an **AWT Button** component, and once you begin using **Swing** buttons you may choose to never again use an **AWT** button*) , the basic functionality of **Swing** is built upon the functionality of the **AWT** .

Therefore, as students, we cannot simply skip over an understanding of the **AWT** and move on to **Swing** . The **AWT** is the foundation for **Swing** .

We must first understand the **AWT** and then understand how **Swing** extends and improves on the **AWT** . I will attempt to integrate an understanding of both the **AWT** and **Swing** in the remaining modules in this collection.

We will begin by introducing you to a few simple components of each type and use these components to teach you about such topics as event-driven programming, layout, graphics, etc. Then, time permitting, we will dig a little deeper into the more complex aspects of both the **AWT** and **Swing** components and other features.

What I won't do is show you a lot of pictures of various **AWT** and **Swing** components as is the case with many books and other tutorials (*although such pictures can be important for an appreciation of GUI programming*) . (*Have you noticed how many Java books use copies of the JavaSoft documentation as filler material to make the book appear to contain more information than it actually contains? At least half of many of the books currently in print is nothing more than a reproduction of the documentation that you can download for free from JavaSoft. Oh well, enough of that!*)

If you want to see some pictures of **AWT** and **Swing** components (*which would be only natural*) , you can create them yourself on your own computer screen.

For examples of the **AWT** components, simply look in the folders in the software that you downloaded from JavaSoft. When you install JDK 1.1.6, a folder named "demo" will be created that contains about two-dozen sample programs. Many of these sample programs have graphical user interfaces that make use of the **AWT** . Just run the programs to see examples of the use of the **AWT** .

When you download and install **Swing** 1.0.1, a folder named "examples" will be created. This folder contains about nine folders, each of which contains a demonstration application or applet that makes use of **Swing** . You can run these programs to see the examples on your computer screen.

A particularly interesting demonstration application is the one named **SwingSet** . One of the new components in **Swing** is a tabbed pane that looks much like a common cardboard file folder with a labeled tab on the top, bottom, left, or right. The **AWT** doesn't contain such a component.

This demonstration starts with about twenty such tabbed panes on the screen, each one of which demonstrates one aspect of the use of **Swing** . By clicking on each of the labeled tabs, you can select and exercise one aspect of **Swing** . In addition, there are five menus that contain selections, some of which impact the behavior of some aspect of the demonstration.

While you are there, pay attention to the fact that virtually all of the **Swing** components are also containers, so it is possible to cause other items (*such as images*) to be contained in components such as

buttons and menus.

Take a look at the pane labeled *RadioButtons* and see how two different images of JavaSoft's little creature named Duke can be made to function as a radio button. In this case, the selected Duke is waving while the unselected Dukes aren't waving.

Duke shows up again under *ToggleButtons* where the button which has been toggled has Duke animated in a child's swing.

The *Checkboxes* pane uses light bulbs that either are or are not illuminated to illustrate selection of **Checkbox** items.

The examples on the *Slider* pane are truly impressive (*the AWT doesn't have a slider component, although it is possible to use a ScrollBar as a crude slider*).

Take a look at the *ListBox* pane to see another example of using images inside of a component.

The *DebugGraphics* pane demonstrates how to run your program in slow motion so that you can see how the components are assembled for debugging purposes. Note that a **Slider** is used to control the speed of assembly of the components.

And of course, every where you turn in this demo, you will see *tool tips* that are not a part of the **AWT**. For a little comic relief, take a look at the *ToolTips* pane.

Don't forget to pull down the *Options* menu and select the "look and feel" of the different panes as you view them.

Actually, words are inadequate to describe what you are going to find when you install and run the **SwingSet** demonstration. To use a corny phrase made famous by an old TV commercial (*which many of you are probably too young to remember*), "Try it, you'll like it."

4.4.2.1.4 What's next?

The next module in the collection will take a first look at *callbacks*.

4.4.2.1.5 Miscellaneous

This section contains a variety of miscellaneous information.

- Listing 8 (p. 1450) . Define the method named register.
- Listing 9 (p. 1451) . The unRegister method.
- Listing 10 (p. 1452) . Define the callTheRoll method.
- Listing 11 (p. 1452) . Define the class named Dog.
- Listing 12 (p. 1453) . Define the class named Callback02.
- Listing 13 (p. 1455) . Complete listing of program named Callback02.

4.4.2.2.3 Preview

Many processes in the standard Java API make use of a mechanism that might be referred to as a *callback* mechanism. Basically, this is a mechanism where a method in one object asks a method in another object to "call me back" or "notify me" when an interesting event happens.

An interesting event

For example, an interesting event might be that the price of a specified stock goes above its previous high value, or the toaster finishes toasting the bread.

Multicasting

In fact, many different objects may ask one object to notify them when the interesting event happens. This is sometimes referred to as *multicasting* . (*The one-to-one case is often referred to as unicasting.*)

Going further, many different objects may ask one object to notify them when any interesting event in a family of interesting events happens, and to identify the specific event that actually happened along with the notification.

Many examples

For example, we see different forms of callback activity in conjunction with

- the *Delegation Event Model* used with GUIs in JDK 1.1,
- the *Observer/Observable* concept used in the *Model-View-Controller* paradigm,
- the concept of *Bound Properties* and *Constrained Properties* in *Java Beans* , etc.

You can find examples of all of these in the pages of my online tutorial lessons.

Callback implementation

Callback capabilities are often implemented in other languages by passing a function pointer to another function. The receiving function uses the passed function pointer to call another function when an interesting event happens. However, Java doesn't support function pointers. In this module, we will learn how to implement the callback mechanism using **interfaces** instead.

From the simple to the more complex

As usual, our approach will be to learn the material by reviewing programs that progress from very simple to more complex. As mentioned earlier, this topic consumes all of this module and two additional lessons on my website as well.

Meaningful scenarios

It is usually easier to understand abstract concepts if they are explained in terms of meaningful scenarios. In this case, our scenario will consist of a *teacher* and some *students* . In the beginning there will only be one student. Ultimately there will be many students and there will also be some animals in the classroom as well.

Registration

The students (*and the animals*) register themselves on the teachers roll book to be notified of interesting events. Initially the interesting event will simply be the teacher taking the roll. Ultimately the interesting event will be notification that it is *either* time for recess, *or* it is time for lunch.

Unicast and multicast scenarios

Initially, only one student receives notification of the one type of event. Ultimately, all of the students and all of the animals receive notification of both types of event (*recess or lunch*) but some of those who are notified choose to ignore the notification.

We will refer to the case where only one student is on the list as the *unicast* program. We will refer to the case where many students (*and possibly animals as well*) are on the list as the *multicast* program. This terminology was selected because it matches the terminology used in the JDK 1.1 documentation for the Delegation Event Model.

Without further discussion, let's look at some code.

4.4.2.2.4 Discussion and sample code

4.4.2.2.4.1 Unicast sample program

The purpose of this program is to develop a *callback* capability using *Interfaces* . This version of the program is designed to emphasize the structure of the process. Therefore an effort was made to avoid the requirement for any extra code so it doesn't do anything fancy.

A Callback interface

This program defines a **Callback** interface (*interface named **Callback***) that can be used to establish a new type of object reference, and also to declare the interface to a method named **callBack** that will be contained in all objects of classes that implement the interface. This method will then be used to notify those objects whenever something interesting happens.

A Teacher class

The program defines a **Teacher** class that has the ability to

- create and maintain a list of (*only*) one object of the interface type (*multiple objects come later*) , and
- to notify that object that something interesting has happened by calling its **callBack** method.

(As mentioned earlier, the size of the list was constrained to only one object in order to emphasize callback structure and avoid getting bogged down in list processing. A subsequent version will implement list processing.)

A Student class

The program defines a class named **Student** that *implements* the **Callback** interface. Objects of the **Student** class can be *registered* on the list maintained by an object of the **Teacher** class, and can be *notified* by the object of the **Teacher** class whenever something interesting happens. Notification takes the form of calling the **callBack** method on the object.

The method named callBack

The body of the **callBack** method can be designed to do anything, but in this case, to keep things simple, it just announces that it has been called.

The controlling class

Finally, the program defines a controlling class named **Callback01** that ties all the pieces together and exercises them.

The program was originally tested using JDK 1.1.3 under Win95 and more recently tested using JDK 1.7 under Windows Vista.

The output from the program is shown in the complete program listing in a later section.

Interesting unicast code fragments

Listing 1 (p. 1444) defines an interface named **Callback** that creates a new type and declares a generic method named **callBack** that can be used to execute a callback on any object that is instantiated from a class that implements the interface.

Listing 1 . Define the Callback interface.

```

interface Callback{
public void callBack();
} //end interface Callback

```

Table 4.202**A class that can register and notify objects of type Callback**

Next we need a class whose objects can maintain a list of references to objects of type **Callback** (*objects whose class implements the **Callback** interface*).

We refer to the process of putting an object on the list is *registering* the object.

This class also needs to have the ability to notify all the objects on that list when something interesting happens. We will name this class **Teacher** in keeping with the scenario described earlier.

As mentioned earlier, to keep things simple, and emphasize the callback structure without getting bogged down in list processing, we will begin with a limitation of one object for the length of the list.

The unicast class named Teacher

The unicast **Teacher** class consists of one instance variable of type **Callback** (*the interface type*) and two instance methods.

One of the methods named **register** places an object on the list. The other method named **callTheRoll** calls the **callBack** method on the object that is on the list.

Note that the object on the list is guaranteed to have a method named **callBack** because it implements the **Callback** interface. Otherwise, it couldn't get on the list in the first place. This is because the **register** method requires the incoming object's reference to be of type **Callback**.

The Teacher class is defined in Listing 2 (p. 1444).

Listing 2 . Define the Teacher class.

```

class Teacher{
Callback obj; //list of objects of type Callback
//-----//

//Method to add objects to the list.
void register(Callback obj){
    this.obj = obj;
} //end register()
//-----//

//Method to notify all objects on the list
void callTheRoll(){
    obj.callBack();
} //end callTheRoll()
//-----//
} //end class Teacher

```

Table 4.203

A class that implements the Callback interface

Next, we need a class that *implements* the **Callback** interface. Objects of this class can be registered on the list maintained by an object of the **Teacher** class, and will be *notified* whenever that object calls the **callback** method on the registered objects on the list. In keeping with the scenario described earlier, we will name this class **Student** .

By claiming to implement the **Callback** interface, this class is required to provide a concrete definition for the method named **callback** that is declared in the interface. Otherwise, the program won't compile. In this case, that definition is rather simple. The **callback** method simply announces that it has been called.

The callback mechanism

As we saw above, an object of the **Teacher** class will call the **callback** method on all objects on its list when the interesting event occurs. It is important to note that the callback mechanism is to call this method.

The **Student** class is defined in Listing 3 (p. 1445) .

Listing 3 . Define the Student class.

```

class Student implements Callback{
String name;
//-----//

Student(String name){//constructor
    this.name = name; //save the name to identify the obj
} //end constructor
//-----//

public void callback(){
    System.out.println(name + " here");
} //end callback()
} //end class Student

```

Table 4.204

A controlling class named Callback01

Finally, we need a controlling class to tie all the pieces together and to exercise them. The **main** method in this class

- instantiates an object of the **Teacher** class named **missJones** ,
- instantiates an anonymous **Student** object named " **Joe** ",
- registers the object on the list maintained by **missJones** , and
- calls the **callTheRoll** method on **missJones** to cause the objects on the list to be notified (to cause their **callback** methods to be called).

This is not too complicated once you break the process into its component parts.

The class named **Callback01** is defined in Listing 4 (p. 1446) .

Listing 4 . A controlling class named Callback01.

```

class Callback01{
public static void main(String[] args){
  //Instantiate Teacher object
  Teacher missJones = new Teacher();
  //Instantiate and register a Student object with the
  // Teacher object
  missJones.register(new Student("Joe"));
  //Cause the Teacher object to do a callBack on the
  // Student object.
  missJones.callTheRoll();
} //end main()
} //end class Callback01

```

Table 4.205

There you have it. This simple program contains the sum and substance of one approach to callbacks in Java.

It is critical to note that the objects registered on the list are of the interface type **Callback** . This guarantees that there cannot be an object on the list that does not have an instance method named **callBack**

Unicast Program Listing

A complete listing of the program is provided in Listing 5 (p. 1446) so that you can view the code fragments in context.

Listing 5 . Complete listing of program named Callback01.

```

/*File Callback01.java Copyright 1997, R.G.Baldwin
The purpose of this program is to develop a callback
capability using Interfaces. This version of the
program is designed to emphasize the structure of
the process, and therefore an effort was made to
avoid the requirement for any extra code to do
anything fancy.

```

Tested using JDK 1.1.3 under Win95.

The output from the program is:

```

Joe here.
*****/
//First we define an interface that will create a new type
// and declare a generic method that can be used to
// callback any object that is of a class that implements
// the interface.
interface Callback{
  public void callBack();
} //end interface Callback
//=====//

```

```

//Next we need a class whose objects can maintain a
// registered list of objects of type Callback (whose
// class implements the Callback interface) and can
// notify all the objects on that list when something
// interesting happens.

//To keep things simple, and emphasize the structure of
// what we are doing, we will begin with a limitation
// of one object on the length of the list.

class Teacher{
    Callback obj; //list of objects of type Callback
    //-----//

    //Method to add objects to the list.
    void register(Callback obj){
        this.obj = obj;
    }//end register()
    //-----//

    //Method to notify all objects on the list that
    // something interesting has happened.
    void callTheRoll(){
        //Call the callBack() method on the object. The
        // object is guaranteed to have such a method because
        // it is of a class that implements the Callback
        // interface.
        obj.callBack();
    }//end callTheRoll()
    //-----//
}//end class Teacher
//=====//

//Class that implements the Callback interface. Objects
// of this class can be registered on the list maintained
// by an object of the Teacher class, and will be notified
// whenever that object calls the callBack method on the
// registered objects on the list.
class Student implements Callback{
    String name;
    //-----//

    Student(String name){//constructor
        this.name = name; //save the name to identify the obj
    }//end constructor
    //-----//

    //An object of the Teacher class will call this method
    // as the callback mechanism to notify an object of this
    // class that something interesting has happened.

```

```

    public void callBack(){
        System.out.println(name + " here");
    }//end overridden callBack()
}//end class Student
//=====//

//Controlling class that ties all the pieces together and
// exercises them.
class Callback01{
    public static void main(String[] args){
        //Instantiate Teacher object
        Teacher missJones = new Teacher();
        //Instantiate and register a Student object with the
        // Teacher object
        missJones.register(new Student("Joe"));
        //Cause the Teacher object to do a callBack on the
        // Student object.
        missJones.callTheRoll();
    }//end main()
}//end class Callback01
//=====/

```

4.4.2.2.4.2 Multicast sample program

The multicast version of this program does not modify the basic callback mechanism developed in the previous program. It simply enhances that mechanism to make it possible to maintain a *list of objects* registered for callback and to notify all the objects on that list when an interesting event happens.

In case you started reading at this point, this is an enhanced version of the program named **Callback01**. You should familiarize yourself with that program before trying to understand this program.

A list of registered objects

This program has the capability to create and maintain a list of objects that register for callback whereas the program named **Callback01** could only remember a single object for callback.

Multiple classes implement Callback interface

In addition, this program defines two different classes that implement the **Callback** interface. Mixed objects of those two types are maintained on the list and notified at callback time. This is a subtle but very important point. It is not necessary that all the objects that are registered on a callback list be of the same class type, only that they all be of a class that implements the **Callback** interface.

The Callback interface

As before, this program defines a **Callback** interface that establishes a new type of object, and also declares the interface to a method named **callBack** that is contained in all objects of classes that implement the interface. Because the **callBack** method is guaranteed to be contained in all of the objects on the list, it can be used to notify those objects whenever something interesting happens.

The Teacher class

The program defines a **Teacher** class that creates and maintains a list of objects of the **Callback** interface type, and notifies those objects that something interesting has happened by calling the **callBack** method on each of the objects on the list.

The size of the list is limited only to the largest **Vector** object that can be accommodated by the system. (*See the Java documentation or my online tutorials for information about the **Vector** class.*)

The Student and Dog classes

The program defines a class named **Student** that implements the **Callback** interface. The program also defines a class named **Dog** that implements the **Callback** interface as well. (*Back in the description*

of the scenario, I promised you that `missJones` was going to have to deal with animals in the classroom. I'm glad I don't have that problem.)

Registration and notification of Student and Dog objects

Objects of the `Student` and `Dog` classes can be *registered* on the list (of `CallBack` objects) maintained by an object of the `Teacher` class (because they both implement the `CallBack` interface), and can be *notified* by the object of the `Teacher` class whenever something interesting happens.

Addition and removal from the list

Note that objects can be added to the list and then removed from the list. One object is first added and later removed for demonstration purposes.

The callback mechanism

As before, notification takes the form of calling the `callBack` method on each of the objects on the list.

Behavior of the callBack methods

The behavior of the `callBack` methods in the classes that implement the interface can be designed to do anything. In this case, to keep things simple, they just announce that they have been called. However, they make the announcement in slightly different ways.

Text display statements

This program contains display statements in the registration and notification methods for demonstration purposes only, and to allow us to track what is happening as the program runs.

The controlling class

Finally, the program defines a controlling class named `Callback02` that ties all the pieces together and exercises them.

The program was originally tested using JDK 1.1.3 under Win95 and more recently tested using JDK 1.7 under Windows Vista.

The output from the program is shown following a discussion of the controlling class at the end of the next section.

Interesting multicast code fragments

Listing 6 (p. 1449) defines an interface that creates a new type and declares a generic method that can be used to call back any object that is of a class that implements the interface. There is nothing new here.

Listing 6 . Define the CallBack interface.

```
interface CallBack{
    public void callBack();
} //end interface CallBack
```

Table 4.206

A class that can register and notify objects of type CallBack

Next we need a class whose objects can maintain a registered list of objects of type `CallBack` (objects whose class implements the `CallBack` interface) and can *notify* all the objects on that list when something interesting happens. As before, we name this class `Teacher`.

The Teacher class

The `Teacher` class has grown to the point that we will break it into parts and discuss them separately.

There is quite a bit here that is new, due simply to the requirement for list processing. There is nothing new about the basic callback mechanism.

An object of type Vector

We start out by replacing the single instance variable of type `CallBack` by a reference to an object of type `Vector`. We will maintain our list in an object of type `Vector`.

Recall that a **Vector** object can only work with references to objects of type **Object** , so this will entail some down casting later.

*(Editor's note: Sometime around JDK 1.5, a concept known as generics was released into Java, which eliminated the restriction to objects of type **Object** mentioned in the previous paragraph. However, this code has not been updated to take advantage of that capability.)*

The constructor for our new **Teacher** class, which is shown in Listing 7 (p. 1450) , instantiates the **Vector** object.

Listing 7 . Define the Teacher class.

```
class Teacher{
Vector objList; //list of objects of type Callback
//-----//

Teacher(){//constructor
    objList = new Vector();
} //end constructor
```

Table 4.207

The method named register

Next we need a method to add objects to the list. We will synchronize it to protect against the possibility of two or more objects on different threads trying to register at the same time.

Note that the references to the objects are received as type **Callback** , which is the interface type, and stored as type **Object** , because the **Vector** class only accommodates references to objects of type **Object** . *(See the earlier editor's note.)* Again, this will lead to some down casting requirements later.

Listing 8 . Define the method named register.

```
synchronized void register(Callback obj){
this.objList.addElement(obj);
System.out.println(obj + " added");
} //end register()
```

Table 4.208

The unRegister method

To be general, we also need a method to remove objects from the list. Removal of an object from the list is a little more complicated than adding an object to the list due to the possibility of having two or more identical objects on the list. *(We could, and possibly should, guard against that possibility when constructing the list.)*

Figure 1 (p. 1451) contains a partial excerpt from the JDK 1.1.3 documentation, which describes the **removeElement** method of the **Vector** class that we are using to accomplish this *(three different methods are available to remove objects from a **Vector**)*.

Figure 1 . Documentation for the removeElement method.

```
public final synchronized boolean removeElement(Object obj)
```

This method removes the first occurrence of the argument from this vector. Indices beyond that point are adjusted appropriately

Parameters: obj - the component to be removed.

Returns: true if the argument was a component of this vector;
false otherwise.

Table 4.209**Registered object removal code**

Given that explanation, the code for removal of an object from the list is straightforward. The `unRegister` method is shown in Listing 9 (p. 1451) .

Listing 9 . The unRegister method.

```
synchronized void unRegister(CallBack obj){
if(this.objList.removeElement(obj))
System.out.println(obj + " removed");
else System.out.println(obj + " not in the list");
} //end register()
```

Table 4.210**The callTheRoll method**

Now we need a method to notify all of the objects on the list that something interesting has happened. We will name this method `callTheRoll` to adhere to our classroom scenario.

Maintain the integrity of the callback list

One of the potential problems with this type of callback mechanism is that when the callback method is called on an object, that method might take a while to finish.

(As an aside, when writing callback methods, if they do anything significant in terms of time, the code in the method should probably spawn another thread to do the actual work and return as quickly as possible.)

This leads to the possibility that additional objects might attempt to register during that time interval. To protect against this, we make a copy of the state of the list object as it existed at the point in time that the decision was made to do the callbacks, and then perform the callbacks using that copy. That way, the original list is free to be updated as needed during this interval.

So, we start out by creating a clone of the list. We also *synchronize* this process to prevent the list from being modified while we are creating the clone.

Following this, we use a `for` loop to access all the objects on the list, and call the `callback` method on those objects. *(Actually, the list contains references to objects, and not the actual objects, so we are calling the method on the references.)*

As promised earlier, we have to downcast from `Object` to `CallBack` to gain access to the `callback` method in the objects.

Listing 10 . Define the callTheRoll method.

```

void callTheRoll(){
    Vector tempList;//save a temporary copy of list here

    synchronized(this){
        tempList = (Vector)objList.clone();
    }//end synchronized block

    for(int cnt = 0; cnt < tempList.size(); cnt++){
        ((CallBack)tempList.elementAt(cnt)).callBack();
    }//end for loop
}//end callTheRoll()

```

Table 4.211**End of the class named Teacher**

That ends the discussion of the class named **Teacher** and brings us to the class named **Student** that implements the **CallBack** interface. This class hasn't changed. As indicated earlier, this version of the program also has a class named **Dog** that implements the interface. These two classes are essentially the same.

Define the class named Dog

Because of their similarity, and because they are essentially the same as in the previous program, I will simply show the class named **Dog** with no further discussion.

Listing 11 . Define the class named Dog.

```

class Dog implements CallBack{
String name; //store name here for later ID
//-----//

Dog(String name){//constructor
    this.name = name; //save the name to identify the obj
}//end constructor
//-----//

//An object of the Teacher class will call this method
// as the callback mechanism to notify an object of this
// class that something interesting has happened.

public void callBack(){//announce callBack

    System.out.println("Woof, Woof " + name);
}//end overridden callBack()
}//end class Dog

```

Table 4.212

The controlling class

That brings us to the controlling class named **Callback02** that ties all the pieces together and exercises them. This class is shown in Listing 12 (p. 1453) .

Listing 12 . Define the class named Callback02.

```
class Callback02{
    public static void main(String[] args){
        //Instantiate Teacher object
        Teacher missJones = new Teacher();

        //Instantiate some Student objects
        Student tom = new Student("Tom");
        Student sue = new Student("Sue");
        Student peg = new Student("Peg");
        Student bob = new Student("Bob");
        Student joe = new Student("Joe");

        //Instantiate some Dog objects.
        Dog spot = new Dog("Spot");
        Dog fido = new Dog("Fido");
        Dog brownie = new Dog("Brownie");

        //Register some Student and Dog objects with the
        // Teacher object.
        System.out.println("Register Tom");
        missJones.register(tom);
        System.out.println("Register Spot");
        missJones.register(spot);
        System.out.println("Register Sue");
        missJones.register(sue);
        System.out.println("Register Fido");
        missJones.register(fido);
        System.out.println("Register Peg");
        missJones.register(peg);
        System.out.println("Register Bob");
        missJones.register(bob);
        System.out.println("Register Brownie");
        missJones.register(brownie);

        //Remove a Student object from the list.
        System.out.println("Remove Peg");
        missJones.unregister(peg);

        //Try to remove an object that is not on the list.
        System.out.println("Try to remove Joe");
        missJones.unregister(joe);

        System.out.println();//blank line

        //Cause the Teacher object to do a callBack on all
```

```
    // the objects on the list.  
    missJones.callTheRoll();  
  }//end main()  
}//end class Callback02
```

Differences relative to Callback01

This program differs from the previous program primarily in terms of the volume of **Student** and **Dog** objects to be instantiated and registered on the **Teacher** object. There are also a lot of display statements to help us keep track of what is going on.

The ability to remove objects from the list is also illustrated.

Call the roll

Finally, the callback to the objects on the list is executed in Listing 12 (p. 1453) by calling the **callTheRoll** method on the **Teacher** object named **missJones** . The output from running this program is shown later.

Mixed object types

A subtle, but extremely important point is illustrated here. **Student** and **Dog** are different classes. Objects of both of those classes are registered on the single object of the **Teacher** class. The **Teacher** object doesn't care that they are different, so long as they are all instantiated from classes that implement the **CallBack** interface. The **register** method will only accept object references of type **CallBack** .

Program output

The output from running this program is shown in Figure 2 (p. 1455) . You can see the identification of each individual object as it is added to, or removed from the list.

Figure 2 . Output from Callback02.

```

    Register Tom
Student@1cc73e added
Register Spot
Dog@1cc74e added
Register Sue
Student@1cc741 added
Register Fido
Dog@1cc751 added
Register Peg
Student@1cc744 added
Register Bob
Student@1cc747 added
Register Brownie
Dog@1cc754 added
Remove Peg
Student@1cc744 removed
Try to remove Joe
Student@1cc74a not in the list

Tom here
Woof, Woof Spot
Sue here
Woof, Woof Fido
Bob here
Woof, Woof Brownie

```

Table 4.213

Note that the attempt to remove Joe from the list was not successful because he was never registered in the first place.

Finally, you see the output produced by calling `callTheRoll` which in turn calls the `callBack` method on each of the objects on the list.

Note that Peg didn't appear in the roll call because she was first added and then removed from the list before the roll call was taken.

The sum and substance

So there you have it, the sum and substance of multicast callbacks in Java. Obviously improvements could be made. You can see a couple of them in the remaining two tutorial lessons on callbacks that are published on my website.

Multicast Program Listing

A complete listing of the multicast program named `Callback02` is provided in Listing 13 (p. 1455) .

Listing 13 . Complete listing of program named Callback02.

```

/*File Callback02.java Copyright 1997, R.G.Baldwin
The purpose of this program is to develop a callback
capability using Interfaces.

```

This is an enhanced version of the program named

Callback01. You should familiarize yourself with the earlier program before getting into this program.

This version has the added capability to create and maintain a list of objects that register for callback whereas the program named Callback01 could only remember a single object for callback.

Tested using JDK 1.1.3 under Win95.

The output from the program was:

```
Register Tom
Student@1cc73e added
Register Spot
Dog@1cc74e added
Register Sue
Student@1cc741 added
Register Fido
Dog@1cc751 added
Register Peg
Student@1cc744 added
Register Bob
Student@1cc747 added
Register Brownie
Dog@1cc754 added
Remove Peg
Student@1cc744 removed
Try to remove Joe
Student@1cc74a not in the list
```

```
Tom here
Woof, Woof Spot
Sue here
Woof, Woof Fido
Bob here
Woof, Woof Brownie
```

Note that Peg didn't appear in the callBack list because she was first added to, and later removed from the list.

```
*****/
import java.util.*;
```

```
//First we define an interface that will create a new type
// and declare a generic method that can be used to
// callback any object that is of a class that implements
// the interface.
interface CallBack{
    public void callBack();
} //end interface CallBack
//=====//
```

```

//Next we need a class whose objects can maintain a
// registered list of objects of type Callback (whose
// class implements the Callback interface) and can
// notify all the objects on that list when something
// interesting happens.

class Teacher{
    Vector objList; //list of objects of type Callback
    //-----//

    Teacher(){//constructor
        //Instantiate a Vector object to contain the list
        // of registered objects.
        objList = new Vector();
    }//end constructor
    //-----//

    //Method to add objects to the list. Synchronize to
    // protect against two or more objects on different
    // threads trying to register at the same time. Note
    // that the objects are received as type Callback which
    // is the interface type, and stored as type Object,
    // because the Vector class only accommodates objects of
    // type Object.
    synchronized void register(Callback obj){
        this.objList.addElement(obj);
        System.out.println(obj + " added");
    }//end register()
    //-----//

    //Method to remove objects from the list.
    synchronized void unregister(Callback obj){
        if(this.objList.removeElement(obj))
            //true when successfully found and removed
            System.out.println(obj + " removed");
        else//false on failure to find and remove
            System.out.println(obj + " not in the list");
    }//end register()
    //-----//

    //Method to notify all objects on the list that
    // something interesting has happened.
    void callTheRoll(){
        Vector tempList;//save a temporary copy of list here

        //Make a copy of the list to avoid the possibility of
        // the list changing while objects are being notified.
        // Synchronize to protect against list changing while
        // making the copy.
        synchronized(this){

```

```

    tempList = (Vector)objList.clone();
} //end synchronized block

//Call the callBack() method on each object on
// the list. The object are guaranteed to have such
// a method, even if they are of different types,
// because they are all of a class that implements
// the Callback interface. If not, they could not
// have been registered on the list in the first
// place. Note the requirement to downcast to
// type Callback.
for(int cnt = 0; cnt < tempList.size(); cnt++){
    ((Callback)tempList.elementAt(cnt)).callBack();
} //end for loop
} //end callTheRoll()
//-----//
} //end class Teacher
//=====//

//Class that implements the Callback interface. Objects
// of this class can be registered on the list maintained
// by an object of the Teacher class, and will be notified
// whenever that object calls the callBack method on the
// registered objects on the list. This program will not
// compile if this class fails to implement the Callback
// interface

class Student implements Callback{
    String name; //store the object name here for later ID
    //-----//

    Student(String name){ //constructor
        this.name = name; //save the name to identify the obj
    } //end constructor
    //-----//

    //An object of the Teacher class will call this method
    // as the callback mechanism to notify an object of this
    // class that something interesting has happened.

    public void callBack(){ //announce callBack
        System.out.println(name + " here");
    } //end overridden callBack()
} //end class Student
//=====//

//Another Class that implements the Callback interface.
// Objects of this class can also be registered on the list
// maintained by an object of the Teacher class, and will
// also be notified whenever that object calls the
// callBack() method on the registered objects on the

```

```

// list. This program will not compile if this class
// fails to implement the Callback interface.

class Dog implements Callback{
    String name; //store name here for later ID
    //-----//

    Dog(String name){//constructor
        this.name = name; //save the name to identify the obj
    }//end constructor
    //-----//

    //An object of the Teacher class will call this method
    // as the callback mechanism to notify an object of this
    // class that something interesting has happened.

    public void callBack(){//announce callBack
        System.out.println("Woof, Woof " + name);
    }//end overridden callBack()
}//end class Dog
//=====//

//Controlling class that ties all the pieces together and
// exercises them.
class Callback02{
    public static void main(String[] args){
        //Instantiate Teacher object
        Teacher missJones = new Teacher();

        //Instantiate some Student objects
        Student tom = new Student("Tom");
        Student sue = new Student("Sue");
        Student peg = new Student("Peg");
        Student bob = new Student("Bob");
        Student joe = new Student("Joe");

        //Instantiate some Dog objects.
        Dog spot = new Dog("Spot");
        Dog fido = new Dog("Fido");
        Dog brownie = new Dog("Brownie");

        //Register some Student and Dog objects with the
        // Teacher object.
        System.out.println("Register Tom");
        missJones.register(tom);
        System.out.println("Register Spot");
        missJones.register(spot);
        System.out.println("Register Sue");
        missJones.register(sue);
        System.out.println("Register Fido");
        missJones.register(fido);
    }
}

```

```

System.out.println("Register Peg");
missJones.register(peg);
System.out.println("Register Bob");
missJones.register(bob);
System.out.println("Register Brownie");
missJones.register(brownie);

//Remove a Student object from the list.
System.out.println("Remove Peg");
missJones.unregister(peg);

//Try to remove an object that is not on the list.
System.out.println("Try to remove Joe");
missJones.unregister(joe);

System.out.println();//blank line

//Cause the Teacher object to do a callBack on all
// the objects on the list.
missJones.callTheRoll();
} //end main()
} //end class Callback02
//=====//

```

4.4.2.2.5 Run the program

I encourage you to copy the code from Listing 5 (p. 1446) and Listing 13 (p. 1455) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.2.2.6 Summary

In this module, you learned the fundamentals of callbacks using interfaces in Java.

4.4.2.2.7 What's next?

In the next module, you will learn about something that goes by the name Delegation Event Model along with a few other names as well.

4.4.2.2.8 Miscellaneous

This section contains a variety of miscellaneous information.

4.4.2.3.2 Preface

This is a page from the Event Handling ¹⁴⁶ section of the book titled ITSE2317 - Java Programming (Intermediate) ¹⁴⁷. The **Event Handling** section explains how to write programs that handle events in Java.

This is the second in a series of three consecutive lessons on *Callbacks* in Java. The three lessons are named Callbacks - I, Callbacks - II, and Callbacks - III. Students in Prof. Baldwin's **ITSE 2317 Intermediate Java Programming** classes at ACC are responsible for knowing and understanding all of the material in this lesson.

- Listing 5 (p. 1466) . The program named Callback03.

4.4.2.3.3 Introduction

Many processes in the standard Java API make use of a mechanism that in other programming environments might be referred to as a *callback* mechanism. Basically, this is a mechanism where a method in one object asks a method in another object to "*call me back*" or "*notify me*" when an interesting event happens. For example, an interesting event might be that the price of a specified stock goes above its previous high value, or the toaster finishes toasting the bread.

A previous lesson introduced you to the basic Java callback mechanism using interfaces and walked you through the development of a set of classes that implement a simple multicast form of callback. In that lesson, the definition of the **Callback** interface was limited to a single method declaration. In a real program involving callbacks, many different objects may ask one object to notify them when any interesting event in a family of interesting events happens, and to identify the specific event that actually happened along with the notification.

This lesson will enhance our previous program to accommodate this possibility. As mentioned in the earlier lesson, it is usually easier to understand abstract concepts if they are explained in terms of a meaningful scenario. For that reason, we have conjured up a scenario in which to develop and explain our callback programs.

Our scenario consists of a teacher and some students. In the beginning there was only one student. Then we expanded the scenario to include many students and some animals in the classroom as well. The students (*and the animals*) register themselves on the teachers roll book to be notified of interesting events. Initially the interesting event was simply the teacher taking the roll. In this lesson, we expand that scenario to include notification that it is either time for recess, or it is time for lunch.

Initially, only one student received notification of one type of event. In this lesson, all of the students and all of the animals receive notification of both types of event (*recess or lunch*) but some of those who are notified choose to ignore the notification. Without further discussion, let's look at some code.

4.4.2.3.4 Sample program

In case you just started reading at this point, this program named **Callback03** is an enhanced version of the program named **Callback02** that you learned about in an earlier ¹⁴⁸ lesson. You should familiarize yourself with the earlier program before trying to understand this program.

The earlier version of the program defined two different classes that implemented the **Callback** interface. In order to give us more to work with, this version defines three different classes named **Student** , **Dog**

¹⁴⁸<http://cnx.org/contents/Rl23r3Lw:0pd-9uyZ>

, and **Cat** that implement the **CallBack** interface. Mixed objects of those three types are registered and maintained on a list and notified at callback time.

As before, this program defines a **CallBack** interface. However, this version of the interface declares two different methods that can be invoked as callback methods instead of just one. In other words, in this case, the objects register to be notified whenever an interesting event from a family of interesting events occurs (*the family has two members*) .

When notified, the objects also need to be advised as to which interesting event actually happened. The methodology for differentiating between the two different kinds of interesting events is to invoke one callback method in the case of one event, and to invoke the other callback method in the case of the other event.

All classes that implement the **CallBack** interface must define both methods, but it is allowable to define the method as an empty method. The net effect of defining a callback method as an empty method is to simply ignore the callback associated with that method. Note however, there is some overhead associated with the invocation of an empty method. (*Although we haven't discussed the topic yet, I believe that this overhead is the reason that JavaSoft chose to separate the **MouseListener** and **MouseMotionListener** interfaces. Perhaps someone will remember to remind me to discuss that when we get to the topic of **MouseMotionListener** interface in the classroom lecture.*)

One of the callback methods in this version of our program is named **recess** and the other callback method is named **lunch** . Thus, registered objects can be notified either of a **recess** event, or of a **lunch** event.

The **Dog** class ignores the recess callback by defining an empty **recess** method, and the **Cat** class ignores the lunch callback by defining an empty **lunch** method. The **Student** class responds to both types of callbacks with fully- defined methods.

The program defines a **Teacher** class that has the ability to create and maintain a list of objects of the interface type, and to notify those objects that something interesting has happened by invoking either the **recess** method or the **lunch** method on all the objects on the list. It is important to note that every object on the list will be notified of both types of callbacks, although as mentioned above, a particular type of callback can be ignored by a class simply by leaving the callback method empty when it is defined.

As before, objects can be added to the list and then removed from the list. However, removal of objects from the list was demonstrated in the previous program, so removal is not demonstrated in this program.

Notification takes the form of invoking either the **recess** method or the **lunch** method on all the objects on the list.

Finally, the program defines a controlling class that ties all the pieces together and exercises them. The program was originally tested using JDK 1.1.3 under Win95. The program was more recently retested using JDK 8 and Win7. The output from the program is shown later.

4.4.2.3.4.1 Interesting code fragments

The code in Listing 1 (p. 1463) defines an interface named **CallBack** that will create a new type and that declares two generic methods that can be used to call back any object that is of a class that implements the interface.

Listing 1 . The CallBack interface.

```
interface CallBack{
    public void recess();
    public void lunch();
} //end interface CallBack
```

Listing 2 (p. 1464) defines a class whose objects can maintain a list of registered objects (*registration is the process of placing an object on the list*) of type **CallBack** and can notify all the objects on that list when something interesting happens. This class differs from the one in the earlier lesson in that it has the ability to notify for two different types of callbacks: **recess** and **lunch** .

The name of this class is **Teacher** . The code to construct the **Teacher** object, add objects to the list, and remove objects from the list hasn't changed in a significant way, so we will skip over that code and go straight to the code that is new and different.

Basically what we now have is two different methods in place of one. One of the methods is named **callRecess** and the other is named **callLunch** . Except for their names, these methods are almost identical to the single method named **callTheRoll** in the earlier lesson, so a lot of discussion isn't needed. The code in the method makes a copy of the list and then uses a **for** loop along with some **Vector** methods to access each object reference. Then the callback method is invoked on each object reference. We will show one of the methods below for reference.

Listing 2 . The callRecess method in the Teacher class.

```
void callRecess(){
    Vector tempList;//save a temporary copy of list here

    //Make a copy of the list.
    synchronized(this){
        tempList = (Vector)objList.clone();
    }//end synchronized block

    //Invoke the recess() method on each object on
    // the list.
    for(int cnt = 0; cnt < tempList.size(); cnt++){
        ((CallBack)tempList.elementAt(cnt)).recess();
    }//end for loop
}//end callRecess()
```

That concludes the discussion of the class named **Teacher** . The **Teacher** class is followed by three class definitions that implement the **CallBack** interface: **Student**, **Dog** , and **Cat**. These class definitions differ from the ones in the earlier lesson in that they define two callback methods instead of just one: **recess** and **lunch** .

Recall that I said that a class can ignore a particular type of callback simply by defining the callback method as an empty method. Recall also that I said that the **Dog** class ignores the **recess()** callback in just this way.

Because of the similarity of these three classes, I am only going to show one of them below. Listing 3 (p. 1464) shows the **Dog** class to illustrate how it defines an empty method to ignore the **recess** callback.

Listing 3 . The Dog class.

```
class Dog implements CallBack{
    String name; //store name here for later ID
    //-----//

    Dog(String name){//constructor
        this.name = name; //save the name to identify the obj
    }//end constructor
    //-----//

    //An object of the Teacher class can invoke this method
    // as the callback mechanism.
```

```

public void recess(){//announce recess
    //ignore this callback with an empty method
} //end overridden recess()
//-----//

//An object of the Teacher class can also invoke this
// method as a callback mechanism.
public void lunch(){//announce recess
    System.out.println(name + " lunch");
} //end overridden lunch()
} //end class Dog

```

That brings us to the controlling class that ties all the pieces together and exercises them (see *Listing 4 (p. 1465)*). Except for the fact that the **main** method triggers two callbacks instead of just one, and the code to remove an object from the list was deleted for brevity, this code is essentially the same as the code in the earlier lesson. Therefore, I am going to delete some of the redundant code from this fragment and primarily show only the new code.

The code in the **main** method of the controlling class instantiates a **Teacher** object named **missJones**, and then instantiates some objects of the three types: **Student**, **Dog**, and **Cat**. These objects are registered for callback by invoking the **register** method on the **Teacher** object.

Then the code triggers a **recess** callback and a **lunch** callback.

Listing 4. The controlling class named `Callback03`.

```

class Callback03{
    public static void main(String[] args){
        //Instantiate Teacher object
        Teacher missJones = new Teacher();

        //Instantiate some Student objects
        //... code deleted for brevity

        //Instantiate some Dog objects.
        //... code deleted for brevity

        //Instantiate some Cat objects
        //... code deleted for brevity

        //Register some Student, Dog, and Cat objects with
        // the Teacher object.
        missJones.register(tom);
        missJones.register(spot);
        missJones.register(sue);
        missJones.register(cleo);
        missJones.register(fido);
        missJones.register(peg);
        missJones.register(kitty);
        missJones.register(bob);
        missJones.register(brownie);
    }
}

```

```

    //Cause the Teacher object to call recess on all
    // the objects on the list.
    missJones.callRecess();
    //Cause the Teacher object to call lunch on all
    // the objects on the list.
    missJones.callLunch();
  }//end main()
} //end class Callback03

```

The output produced by this program is shown in Figure 1 (p. 1466) .

Figure 1. Output from the program named Callback03.

```

Tom recess
Sue recess
CleoCat recess
Peg recess
KittyKat recess
Bob recess
Tom lunch
SpotDog lunch
Sue lunch
FidoDog lunch
Peg lunch
Bob lunch
BrownieDog lunch

```

4.4.2.3.5 Summary

In summary then, we have objects of different classes registered on a common callback list where every object on the list receives a callback for every different type of callback event associated with the list.

The different types of callbacks are established by the method declarations in the **Callback** interface.

Each class of object that registers for callbacks can either respond to all of the different types of callbacks by providing full definitions for all of the callback methods, or can selectively ignore some types of callbacks by defining those callback methods as empty methods.

4.4.2.3.6 Complete program listing

A complete listing of the program named Callback03 is shown in Listing 5 (p. 1466) .

Listing 5 . The program named Callback03.

```

/*File Callback03.java Copyright 1997, R.G.Baldwin
The purpose of this program is to develop a callback
capability using Interfaces.

```

```

This is an enhanced version of the program named
Callback02. You should familiarize yourself with
the earlier program before getting into this program.

```

This version defines three different classes named Student, Dog, and Cat that implement the Callback interface. Mixed objects of those three types are maintained on a list and notified at Callback time.

As before, this program defines a Callback interface that can be used to establish a new type of object.

This version of the interface declares two different methods that can be invoked as callback methods instead of just one. All classes that implement the interface must define both methods, but it is allowable to define the method as an empty method and ignore the callback associated with a particular method.

One of the callback methods is now called recess() and the other is called lunch().

The Dog class ignores the recess() callback by defining an empty method, and the Cat class ignores the lunch() callback by defining an empty method. The Student class responds to both types of callbacks with fully-defined methods.

The program defines a Teacher class that has the ability to create and maintain a list of objects of the interface type, and to notify those objects that something interesting has happened by invoking either the recess() method or the lunch() method on all the objects on the list. It is important to note that every object on the list will be notified of both types of callback, although as mentioned above, a particular type of callback can be ignored simply by leaving the method empty when it is defined.

Note that objects can be added to the list and then removed from the list. However, removal of objects from the list was demonstrated in the previous program, so removal is not demonstrated in this program.

As always, notification takes the form of invoking either the recess() method or the lunch() method on all the objects on the list.

Finally, the program defines a controlling class that ties all the pieces together and exercises them.

Tested using JDK 1.1.3 under Win95.

The output from the program was:

```

Tom recess
Sue recess
CleoCat recess
Peg recess
KittyKat recess
Bob recess
Tom lunch
SpotDog lunch
Sue lunch
FidoDog lunch
Peg lunch
Bob lunch
BrownieDog lunch
*****/
import java.util.*;

//First we define an interface that will create a new type
// and declare two generic methods that can be used to
// callback any object that is of a class that implements
// the interface.
interface Callback{
    public void recess();
    public void lunch();
}//end interface Callback
//=====//

//Next we need a class whose objects can maintain a
// registered list of objects of type Callback and can
// notify all the objects on that list when something
// interesting happens. This class has the ability to
// notify of two different types of callbacks, recess()
// and lunch().

class Teacher{
    Vector objList; //list of objects of type Callback
    //-----//

    Teacher(){//constructor
        //Instantiate a Vector object to contain the list
        // of registered objects.
        objList = new Vector();
    }//end constructor
    //-----//

    //Method to add objects to the list.
    synchronized void register(Callback obj){
        this.objList.addElement(obj);
    }//end register()
    //-----//

    //Method to remove objects from the list.

```

```

synchronized void unRegister(CallBack obj){
    if(this.objList.removeElement(obj))
        System.out.println(obj + " removed");
    else
        System.out.println(obj + " not in the list");
} //end register()
//-----//

//Method to notify all objects on the list that
// something interesting has happened regarding recess.
void callRecess(){
    Vector tempList;//save a temporary copy of list here

    //Make a copy of the list.
    synchronized(this){
        tempList = (Vector)objList.clone();
    } //end synchronized block

    //Invoke the recess() method on each object on
    // the list.
    for(int cnt = 0; cnt < tempList.size(); cnt++){
        ((CallBack)tempList.elementAt(cnt)).recess();
    } //end for loop
} //end callRecess()
//-----//

//Method to notify all objects on the list that
// something interesting has happened regarding lunch.
void callLunch(){
    Vector tempList;//save a temporary copy of list here

    //Make a copy of the list.
    synchronized(this){
        tempList = (Vector)objList.clone();
    } //end synchronized block

    //Invoke the lunch() method on each object on
    // the list.
    for(int cnt = 0; cnt < tempList.size(); cnt++){
        ((CallBack)tempList.elementAt(cnt)).lunch();
    } //end for loop
} //end callRecess()
//-----//
} //end class Teacher
//=====//

//Class that implements the CallBack interface. Objects
// of this class can be registered on the list maintained
// by an object of the Teacher class, and will be notified
// whenever that object invokes either the recess() method
// or the lunch() method on the registered objects on
// the list. This method provides a full definition for

```

```

// both methods.

class Student implements CallBack{
    String name; //store the object name here for later ID
    //-----//

    Student(String name){//constructor
        this.name = name; //save the name to identify the obj
    }//end constructor
    //-----//

    //An object of the Teacher class can invoke this method
    // as a callback mechanism.
    public void recess(){//announce recess
        System.out.println(name + " recess");
    }//end overridden recess()
    //-----//

    //An object of the Teacher class can also invoke this
    // method as a callback mechanism.
    public void lunch(){//announce recess
        System.out.println(name + " lunch");
    }//end overridden lunch()

}//end class Student

//=====//

//Another Class that implements the CallBack interface.
// See description above. This class defines the recess()
// method as an empty method.

class Dog implements CallBack{
    String name; //store name here for later ID
    //-----//

    Dog(String name){//constructor
        this.name = name; //save the name to identify the obj
    }//end constructor
    //-----//

    //An object of the Teacher class can invoke this method
    // as the callback mechanism.

    public void recess(){//announce recess
        //ignore this callback with an empty method
    }//end overridden recess()
    //-----//

    //An object of the Teacher class can also invoke this
    // method as a callback mechanism.

```

```

    public void lunch(){//announce recess
        System.out.println(name + " lunch");
    }//end overridden lunch()
}//end class Dog
//=====================================================//

//A third Class that implements the Callback interface,
// similar to the other two classes. This class defines
// the lunch() method as an empty method.

class Cat implements Callback{
    String name; //store name here for later ID
    //-----//

    Cat(String name){//constructor
        this.name = name; //save the name to identify the obj
    }//end constructor
    //-----//

    //An object of the Teacher class can invoke this method
    // as the callback mechanism.

    public void recess(){//announce recess
        System.out.println(name + " recess");
    }//end overridden recess()
    //-----//

    //An object of the Teacher class can also invoke this
    // method as a callback mechanism.
    public void lunch(){//announce recess
        //ignore this callback with an empty method
    }//end overridden lunch()
}//end class Cat
//=====================================================//

//Controlling class that ties all the pieces together and
// exercises them.
class Callback03{
    public static void main(String[] args){
        //Instantiate Teacher object
        Teacher missJones = new Teacher();

        //Instantiate some Student objects
        Student tom = new Student("Tom");
        Student sue = new Student("Sue");
        Student peg = new Student("Peg");
        Student bob = new Student("Bob");
        Student joe = new Student("Joe");

        //Instantiate some Dog objects.
        Dog spot = new Dog("SpotDog");

```

```

Dog fido = new Dog("FidoDog");
Dog brownie = new Dog("BrownieDog");

//Instantiate some Cat objects
Cat cleo = new Cat("CleoCat");
Cat kitty = new Cat("KittyKat");

//Register some Student, Dog, and Cat objects with
// the Teacher object.
missJones.register(tom);
missJones.register(spot);
missJones.register(sue);
missJones.register(cleo);
missJones.register(fido);
missJones.register(peg);
missJones.register(kitty);
missJones.register(bob);
missJones.register(brownie);

//Cause the Teacher object to call recess on all
// the objects on the list.
missJones.callRecess();
//Cause the Teacher object to call lunch on all
// the objects on the list.
missJones.callLunch();
} //end main()
} //end class Callback03
//=====//

```

4.4.2.4.2 Preface

This is a page from the Event Handling ¹⁵² section of the book titled ITSE2317 - Java Programming (Intermediate) ¹⁵³. The **Event Handling** section explains how to write programs that handle events in Java.

This is the third in a series of three lessons on Callbacks in Java. The three lessons are named Callbacks - I, Callbacks - II, and Callbacks - III. Students in Prof. Baldwin's **ITSE 2317 Intermediate Java Programming** classes at ACC are responsible for knowing and understanding all of the material in this lesson.

4.4.2.4.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Listings while you are reading about them.

¹⁴⁹This content is available online at <<http://cnx.org/content/m59592/1.4/>>.

4.4.2.4.2.1.1 Listings

- Listing 1 (p. 1475) . The interface named `CallBack`.
- Listing 2 (p. 1476) . The class named `CallBackObjectClass`.
- Listing 3 (p. 1476) . The class named `CallBackAdapter`.
- Listing 4 (p. 1477) . Abbreviated version of the `Teacher` class.
- Listing 5 (p. 1477) . The class named `Dog`.
- Listing 6 (p. 1478) . The program named `Callback04`.

4.4.2.4.3 Introduction

Hopefully, by this point, you are familiar with the *callback* material in the earlier lessons. Therefore, I will avoid, insofar as practical, repeating the introductory material from those lessons.

In a real program involving callbacks, many different objects may ask one object to notify them when any interesting event in a family of interesting events happens, and to identify the specific event that actually happened along with the notification.

In addition, it is often desirable to encapsulate information in an object and to pass that object as a parameter when the callback method is invoked. This lesson will enhance the previous program by providing this capability.

Also, sometimes the interfaces used to implement callbacks declare many callback methods, and some classes are interested in only a few of those methods. It can become burdensome to have to provide large numbers of empty methods in all the classes that implement such an interface. For this reason, a mechanism known in Java terms as an **adapter** class is used to reduce the burden.

This lesson will show you how to create and use such **adapter** classes.

We will continue with our earlier scenario consisting of a *teacher* and some *students* . At this point, we have expanded our scenario to include many students and some animals in the classroom.

The students (*and the animals*) register themselves on the teachers roll book to be notified when it is time for recess, or it is time for lunch.

In this lesson, as in the earlier lesson, all of the students and all of the animals receive notification of both types of events (*recess* or *lunch*) but some of those who are notified choose to ignore the notification. However, in this lesson, the methodology for ignoring the notification is different than it was in the previous lesson.

4.4.2.4.4 Sample program

In case you just started reading at this point, this program named **Callback04** is an enhanced version of the earlier program named **Callback03** . You should familiarize yourself with the earlier program before trying to understand this program.

This version of the program makes two unrelated enhancements to the program named **Callback03** .

- First, a new class is defined in conjunction with the **CallBack** interface that makes it possible for the **Teacher** class to encapsulate information into an object and pass that object as a parameter whenever a callback is made.
- Second, a new class is defined in conjunction with the **CallBack** interface which, in Java terminology, is often called an **adapter** class.

An **adapter** class, as defined here, is a convenience class that implements the interface and defines all the methods declared in the interface with empty methods. Then any class that needs to implement the interface can **extend** the adapter class without a requirement to define those methods that are not of interest.

In this version of the program, the **CallBack** interface is expanded to declare several dummy methods to emphasize this benefit of the use of an **adapter** class.

Note that objects of a class that *extends* the adapter class can be referred to by the interface type. Thus, interface type is an inherited attribute that results from *extending* a class that *implements* an interface.

Using an **adapter** class also makes it possible to expand the interface later, by declaring new methods, without breaking code that already **implements** the interface, provided that the **adapter** class is appropriately redefined. In this sense, the **adapter** class is a little more than a convenience class.

This version of the program defines three different classes named **Student** , **Dog** , and **Cat** , that *implement* the **CallBack** interface *indirectly* by extending the adapter class.

Mixed objects of these three types are maintained in a common list and notified at callback time.

As in the previous version of the program, the **Dog** class ignores the **recess** callback and the **Cat** class ignores the **lunch** callback. In this program, these classes simply don't bother to override methods of the interface that are not of interest.

The **Student** class responds to both types of callbacks with fully- defined methods.

The program defines a **Teacher** class that has the ability to create and maintain a list of objects of the interface type, and to notify those objects that something interesting has happened by invoking either the **recess** method or the **lunch** method on all the objects on the list. An object is instantiated and passed as a parameter whenever one or the other of these methods is invoked.

Finally, the program defines a controlling class that ties all the pieces together and exercises them.

The program was originally tested using JDK 1.1.3 under Win95. More recently it was tested using Java 8 and Windows 7.

4.4.2.4.4.1 Interesting code fragments

4.4.2.4.4.1.1 The interface named CallBack

We begin by defining an interface named **CallBack** that will create a new type and will declare two generic methods that can be used to callback any object that is of a class that implements the interface. The interface named **CallBack** is shown in Listing 1 (p. 1475) .

Listing 1 . The interface named CallBack.

```
interface CallBack{
    public void recess(CallBackObjectClass obj);
    public void lunch(CallBackObjectClass obj);

    public void dummy1(CallBackObjectClass obj);
    public void dummy2(CallBackObjectClass obj);
    public void dummy3(CallBackObjectClass obj);
    public void dummy4(CallBackObjectClass obj);
    public void dummy5(CallBackObjectClass obj);
    public void dummy6(CallBackObjectClass obj);

} //end interface CallBack
```

Note that in addition to two methods mentioned above, the interface also declares several additional dummy methods to emphasize the benefit of extending the adapter class that is defined later.

Note also that the methods now require a parameter, which was not the case in earlier lessons. The class for this parameter will be defined soon next.

4.4.2.4.4.1.2 The class named `CallBackObjectClass`

Listing 2 (p. 1476) defines a class from which we can instantiate an object to pass as a parameter in the callback methods. This class can be as simple or as elaborate as needed to convey the amount and type of information needed with the callback. In our case, it contains a single **String** object.

Listing 2 . The class named `CallBackObjectClass`.

```
class CallBackObjectClass{
    String data;

    CallBackObjectClass(String data){//constructor
        this.data = data;
    }//end constructor
}//end CallBackObjectClass
```

4.4.2.4.4.1.3 The class named `CallBackAdapter`

Listing 3 (p. 1476) shows the definition of the adapter class for the **CallBack** interface. This class defines all the interface methods with empty methods.

Listing 3 . The class named `CallBackAdapter`.

```
class CallBackAdapter implements CallBack{
    public void recess(CallBackObjectClass obj){};
    public void lunch(CallBackObjectClass obj){};

    public void dummy1(CallBackObjectClass obj){};
    public void dummy2(CallBackObjectClass obj){};
    public void dummy3(CallBackObjectClass obj){};
    public void dummy4(CallBackObjectClass obj){};
    public void dummy5(CallBackObjectClass obj){};
    public void dummy6(CallBackObjectClass obj){};
}//end class CallBackAdapter
```

Classes that need to *implement* the **CallBack** interface can now

- *extend* the **CallBackAdapter** class,
- *override* only the empty methods of interest, and
- ignore the other methods.

It is important to note that the existence of the **adapter** does not prevent another class from *implementing* the interface instead of *extending* the **adapter** class.

Objects of a class that *extends* the **CallBackAdapter** class can be referenced as the interface type **CallBack** .

4.4.2.4.4.1.4 The class named `Teacher`

Next we need a class whose objects can maintain a list of registered objects of type **CallBack** and can notify all the objects on that list when something interesting happens. This class has the ability to invoke two different callback methods: **recess** and **lunch** .

Obviously, if you have been following this development, you will know by now that this is the class named **Teacher** .

The only thing significantly different about this version of the **Teacher** class is the fact that it instantiates and passes an object of type **CallbackObjectClass** whenever it makes a callback.

Since you have seen this method several times before, and should be very familiar with it by now, I am going to delete most of the code in the class and show you only that portion of the code that invokes the **recess** callback method on all the objects on the list, instantiating and passing an object of type **CallbackObjectClass** as a parameter in each case. The abbreviated version of the **Teacher** class is shown in Listing 4 (p. 1477) .

Listing 4 . Abbreviated version of the Teacher class.

```
class Teacher{
    //code deleted

    void callRecess(){
        //code deleted

        for(int cnt = 0; cnt < tempList.size(); cnt++){
            ((Callback)tempList.elementAt(cnt)).recess(
                new CallbackObjectClass(" Recess"));
        }//end for loop
    }//end callRecess()
    //code deleted

} //end class Teacher
```

4.4.2.4.4.1.5 The class named Dog

That brings us to the three classes that implement the **Callback** interface *indirectly* by *extending* the **CallbackAdapter** class.

Objects of these three classes can be registered on the list maintained by an object of the **Teacher** class, and will be notified whenever that object invokes either the **recess** method or the **lunch** method on the registered objects on the list.

Part of the notification will be an object passed as a parameter to the callback method. Code in the callback method can either ignore that object, or can extract the information from the object and use it.

These three classes are very similar, so I will show you only one of them here. To be consistent with the previous lesson, I will show you the definition for the **Dog** class that ignores the **recess** callback. This class, which is shown in Listing 5 (p. 1477) , also ignores all of the *dummy* methods that were declared in the **Callback** interface in this program.

Listing 5 . The class named Dog.

```
class Dog extends CallbackAdapter{
    String name; //store name here for later ID
    //-----//

    Dog(String name){//constructor
        this.name = name; //save the name to identify the obj
    }//end constructor
```

```

//-----//

//An object of the Teacher class can invoke this
// method as a callback mechanism passing an object
// as a parameter.
public void lunch(CallBackObjectClass obj){//announce
    System.out.println(name + obj.data);
} //end overridden lunch()
//-----//
} //end class Dog

```

Note first that this class *extends* the **CallBackAdapter** class and does not *implement* any interfaces.

Note also that it only overrides the **lunch** method from the **adapter** class, ignoring all of the other empty methods defined in that class. Were it not for the **adapter** class in this case, this **Dog** class definition would have to define the six dummy methods and the **recess** method with empty methods. Therefore, the availability of an adapter class can be a real convenience for the programmer.

Finally, note that code in the **lunch** method extracts the instance variable named **data** and displays that information instead of a literal string as was the case in the earlier versions of this program.

4.4.2.4.4.1.6 The controlling class named Callback04

That brings us to the controlling class that ties all the other pieces together and exercises them. The controlling class in this version of the program is no different from that of the earlier version named **Callback03** .

Also, the output from running this version of the program is almost the same as the earlier version, with the main difference being that the callback methods display information encapsulated in an object passed to the method which was not the case in the earlier versions. The output can be seen in the complete program listing shown in Listing 6 (p. 1478) .

Therefore, there should be no need to provide any further discussion regarding the testing of this version of the program.

4.4.2.4.5 Summary

We have objects of different classes registered on a common callback list where every object on the list receives a callback for every different type of callback event associated with the list.

Whenever a callback occurs, an object is instantiated to contain information and passed as a parameter to the callback method. The code in the callback method can either ignore that object, or extract the information from the object and use it. In this program, the code in the callback methods extracts and displays the information encapsulated in the object.

The different types of callbacks are established by the method declarations in the **CallBack** interface.

An **adapter** class is defined that implements the **CallBack** interface and defines all of its methods as empty methods.

Each class of object that registers for callbacks can either respond to all of the different types of callbacks by overriding all of the callback methods in the **adapter** class, or can selectively ignore some types of callbacks simply by not overriding those methods.

Such a class can also ignore the **adapter** class and *implement* the interface directly as in the earlier lessons.

4.4.2.4.6 Complete program listings

A complete listing of the program is shown in Listing 6 (p. 1478) .

Listing 6 . The program named Callback04.

```
/*File Callback04.java Copyright 1997, R.G.Baldwin  
The purpose of this program is to develop a callback  
capability using Interfaces.
```

This is an enhanced version of the program named Callback03. You should familiarize yourself with the earlier program before getting into this program.

This version of the program makes two unrelated enhancements to the program named Callback03.

First, a new class is defined in conjunction with the Callback interface that makes it possible for the Teacher class to encapsulate information into an object and pass that object whenever a callback is made.

Second, a new class is defined in conjunction with the Callback interface which, in Java terminology, is often called an adapter class. This is a convenience class that implements the interface and defines all the methods declared in the interface with empty methods. Then any class that needs to implement the interface can extend the adapter class without a requirement to define those methods that are not of interest.

In this case, the interface is expanded to declare several dummy methods to emphasize this benefit of the use of an adapter class.

Note that objects of classes that extend the adapter class that implements the interface can be referred to by the interface type. Thus, interface type is an inherited attribute that results from extending a class.

Using an adapter class also makes it possible to expand the interface later by declaring new methods without breaking code that already implements the interface.

This version defines three different classes named Student, Dog, and Cat, that implement the Callback interface indirectly by extending the adapter class. These classes simply don't bother to define methods of the interface that are not of interest.

Mixed objects of these three types are maintained on a list and notified at Callback time.

The Dog class ignores the recess() callback and the Cat class ignores the lunch() callback. The Student class responds to both types of callbacks with fully-

defined methods.

The program defines a Teacher class that has the ability to create and maintain a list of objects of the interface type, and to notify those objects that something interesting has happened by invoking either the recess() method or the lunch() method on all the objects on the list.

Finally, the program defines a controlling class that ties all the pieces together and exercises them.

Tested using JDK 1.1.3 under Win95.

The output from the program was:

```
Tom Recess
Sue Recess
CleoCat Recess
Peg Recess
KittyKat Recess
Bob Recess
Tom Lunch
SpotDog Lunch
Sue Lunch
FidoDog Lunch
Peg Lunch
Bob Lunch
BrownieDog Lunch
```

```

import java.util.*;

//First we define an interface that will create a new type
// and declare two generic methods that can be used to
// callback any object that is of a class that implements
// the interface. Note that the methods now require a
// parameter. Note also that we have declared several
// additional dummy methods to emphasize the benefit of
// extending the adapter class that is defined later.
interface CallBack{
    public void recess(CallBackObjectClass obj);
    public void lunch(CallBackObjectClass obj);

    public void dummy1(CallBackObjectClass obj);
    public void dummy2(CallBackObjectClass obj);
    public void dummy3(CallBackObjectClass obj);
    public void dummy4(CallBackObjectClass obj);
    public void dummy5(CallBackObjectClass obj);
    public void dummy6(CallBackObjectClass obj);
}

//end interface CallBack
```

```

//=====//

//Now we need a class that can be instantiated to
// pass an object in the callback methods.
class CallBackObjectClass{
    String data;

    CallBackObjectClass(String data){//constructor
        this.data = data;
    }//end constructor
}//end CallBackObjectClass
//=====//

//Now we need an adapter class for the CallBack interface.
// This class defines all the interface methods with
// empty methods. Classes that need the interface can
// now extend this class and override only the empty
// methods of interest, and ignore the others. Note that
// objects of a class that extends this class can be
// referenced as the interface type CallBack.
class CallBackAdapter implements CallBack{
    public void recess(CallBackObjectClass obj){};
    public void lunch(CallBackObjectClass obj){};

    public void dummy1(CallBackObjectClass obj){};
    public void dummy2(CallBackObjectClass obj){};
    public void dummy3(CallBackObjectClass obj){};
    public void dummy4(CallBackObjectClass obj){};
    public void dummy5(CallBackObjectClass obj){};
    public void dummy6(CallBackObjectClass obj){};
}//end class CallBackAdapter
//=====//

//Next we need a class whose objects can maintain a
// registered list of objects of type CallBack and can
// notify all the objects on that list when something
// interesting happens. This class has the ability to
// notify two different types of callbacks, recess()
// and lunch().

class Teacher{
    Vector objList; //list of objects of type CallBack
    //-----//

    Teacher(){//constructor
        //Instantiate a Vector object to contain the list
        // of registered objects.
        objList = new Vector();
    }//end constructor
    //-----//

```

```

//Method to add objects to the list.
synchronized void register(CallBack obj){
    this.objList.addElement(obj);
} //end register()
//-----//

//Method to remove objects from the list.
synchronized void unregister(CallBack obj){
    if(this.objList.removeElement(obj))
        System.out.println(obj + " removed");
    else
        System.out.println(obj + " not in the list");
} //end register()
//-----//

//Method to notify all objects on the list that
// something interesting has happened regarding
// recess and to pass information to the object
// encapsulated in an object as a parameter.
void callRecess(){
    Vector tempList;//save a temporary copy of list here

    //Make a copy of the list.
    synchronized(this){
        tempList = (Vector)objList.clone();
    } //end synchronized block

    //Invoke the recess() method on each object on
    // the list, passing an object as a parameter.
    for(int cnt = 0; cnt < tempList.size(); cnt++){
        ((CallBack)tempList.elementAt(cnt)).recess(
            new CallBackObjectClass(" Recess"));
    } //end for loop
} //end callRecess()
//-----//

//Method to notify all objects on the list that
// something interesting has happened regarding
// lunch and to pass an object containing information
// as a parameter to the callback method.
void callLunch(){
    Vector tempList;//save a temporary copy of list here

    //Make a copy of the list.
    synchronized(this){
        tempList = (Vector)objList.clone();
    } //end synchronized block

    //Invoke the lunch() method on each object on
    // the list, passing an object as a parameter.
    for(int cnt = 0; cnt < tempList.size(); cnt++){
        ((CallBack)tempList.elementAt(cnt)).lunch(

```

```

        new CallBackObjectClass(" Lunch"));
    }//end for loop
} //end callRecess()
//-----//
} //end class Teacher
//=====//

//Class that implements the CallBack interface indirectly
// by extending the CallBackAdapter class. Objects
// of this class can be registered on the list maintained
// by an object of the Teacher class, and will be notified
// whenever that object invokes either the recess() method
// or the lunch() method on the registered objects on
// the list. This method provides a full definition for
// both methods.

class Student extends CallBackAdapter{
    String name; //store the object name here for later ID
    //-----//

    Student(String name){//constructor
        this.name = name; //save the name to identify the obj
    } //end constructor
    //-----//

    //An object of the Teacher class can invoke this method
    // as a callback mechanism. Note that this method
    // displays the data encapsulated in the incoming
    // object.
    public void recess(CallBackObjectClass obj){//announce
        System.out.println(name + obj.data);
    } //end overridden recess()
    //-----//

    //An object of the Teacher class can also invoke this
    // method as a callback mechanism passing an object
    // as a parameter.
    public void lunch(CallBackObjectClass obj){//announce
        System.out.println(name + obj.data);
    } //end overridden lunch()
    //-----//
} //end class Student

//=====//

//Another Class that implements the CallBack interface
// indirectly by extending the CallBackAdapter class.
// See description above. This class ignores the recess()
// method as well as the dummy methods.

class Dog extends CallBackAdapter{

```

```

String name; //store name here for later ID
//-----//

Dog(String name){//constructor
    this.name = name; //save the name to identify the obj
}//end constructor
//-----//

//An object of the Teacher class can invoke this
// method as a callback mechanism passing an object
// as a parameter.
public void lunch(CallBackObjectClass obj){//announce
    System.out.println(name + obj.data);
}//end overridden lunch()
//-----//
}//end class Dog
//=====//

//A third Class that implements the Callback interface
// indirectly by extending the CallbackAdapter class,
// similar to the other two classes. This class ignores
// the lunch() method as well as the dummy methods.

class Cat extends CallbackAdapter{
    String name; //store name here for later ID
    //-----//

    Cat(String name){//constructor
        this.name = name; //save the name to identify the obj
    }//end constructor
    //-----//

    //An object of the Teacher class can invoke this method
    // as the callback mechanism, passing an object as a
    // parameter.
    public void recess(CallBackObjectClass obj){//announce
        System.out.println(name + obj.data);
    }//end overridden recess()
    //-----//
}//end class Cat
//=====//

//Controlling class that ties all the pieces together and
// exercises them.
class Callback04{
    public static void main(String[] args){
        //Instantiate Teacher object
        Teacher missJones = new Teacher();

        //Instantiate some Student objects
        Student tom = new Student("Tom");
    }
}

```

```

Student sue = new Student("Sue");
Student peg = new Student("Peg");
Student bob = new Student("Bob");
Student joe = new Student("Joe");

//Instantiate some Dog objects.
Dog spot = new Dog("SpotDog");
Dog fido = new Dog("FidoDog");
Dog brownie = new Dog("BrownieDog");

//Instantiate some Cat objects
Cat cleo = new Cat("CleoCat");
Cat kitty = new Cat("KittyKat");

//Register some Student, Dog, and Cat objects with
// the Teacher object.
missJones.register(tom);
missJones.register(spot);
missJones.register(sue);
missJones.register(cleo);
missJones.register(fido);
missJones.register(peg);
missJones.register(kitty);
missJones.register(bob);
missJones.register(brownie);

//Cause the Teacher object to call recess on all
// the objects on the list.
missJones.callRecess();
//Cause the Teacher object to call lunch on all
// the objects on the list.
missJones.callLunch();
} //end main()
} //end class Callback04
//=====//

```

4.4.2.5.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

(Editor's note: As you read this module, you will see that it was originally written in 1997. However, despite many improvements in Java since 1997, most of what was true in 1997 is still true in 2012.)

This module makes several references to my website, which is located at <http://www.dickbaldwin.com/toc.htm>¹⁵⁵. A copy of the original html version of this module is available here¹⁵⁶.

4.4.2.5.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

4.4.2.5.2.1.1 Figures

- Figure 1 (p. 1493) . Program output.
- Figure 2 (p. 1504) . Screen output from Event09.

4.4.2.5.2.1.2 Listings

- Listing 1 (p. 1490) . The main method for Event08.
- Listing 2 (p. 1490) . Beginning of the constructor.
- Listing 3 (p. 1491) . Instantiate two Listener objects.
- Listing 4 (p. 1491) . Register the listener objects.
- Listing 5 (p. 1492) . Make the Frame visible.
- Listing 6 (p. 1492) . Beginning of the class named WProc1.

- Listing 15 (p. 1507) . The class named WProc1.
- Listing 16 (p. 1508) . Complete listing of Event09.

4.4.2.5.3 Introduction

This module provides a description of the Delegation Event Model as defined in JDK 1.1 along with sample programs that illustrate some aspects of the model. I describe how the event model maps to the AWT API.

Much of this information was taken from the documentation released with the various versions of JDK 1.1, and is the intellectual property of Sun Microsystems. The material is being reproduced here for the sole purpose of assisting students in learning how to use the event model.

¹⁵⁵<http://www.dickbaldwin.com/toc.htm>

¹⁵⁶<http://cnx.org/content/m45597/latest/Java080.htm>

4.4.2.5.4 Design Goals of the JDK 1.1 Delegation Model

According to Sun, the primary design goals of the event model in the AWT are the following:

Design goals:

- Simple and easy to learn
- Support a clean separation between application and GUI code
- Facilitate the creation of robust event handling code which is less error-prone (strong compile-time checking)
- Flexible enough to enable varied application models for event flow and propagation
- For visual tool builders, enable run-time discovery of both events that a component generates as well as the events it may observe
- Support backward binary compatibility with the old model

It will be up to you to decide if they have met their goals.

4.4.2.5.5 Simplified Overview of the New Delegation Model

First, I will provide a simplified overview of the model including a sample program. Following that, I will embark on a detailed discussion of the model. Hopefully the simplified discussion and the sample program will help you to understand the material in the detailed discussion.

Also, the earlier module on callbacks ¹⁵⁷ should have given you considerable background to help you understand this material. If you are not familiar with the callback material, you should go back and review that material.

Event sources and listeners

Events are now organized into a hierarchy of event classes. The model makes use of **event sources** and **event listeners** .

An event **source** is an object that has the ability

- to determine when an interesting event has occurred, and
- to notify listener objects of the occurrence of the event.

Although you as the programmer establish the framework for such notification, the actual notification takes place automatically behind the scenes.

A **listener** object is an instance of a class (*or instance of a subclass of a class*) that

- implements a specific listener interface.

A number of listener interfaces are defined where each interface declares the methods appropriate for a specific class of events. Thus, there is natural pairing of classes of events and interface definitions.

For example, there is a class of mouse events that includes most of the events normally associated with mouse action. There is a matching interface definition, which is used to define a listener class for those events (*actually this is the one case where two interfaces are defined to match up with a single event class*) .

Registration

A listener object can be *registered* on a source object to be notified of the occurrence of all events of the specific class for which the listener object is designed.

Once a listener object is registered to be notified of those events, the occurrence of an event defined by the specified class will automatically call the matching method in the listener object. The code in the body of the method is designed by the programmer to perform the desired action when the event occurs.

Multiple notification methods

¹⁵⁷<http://cnx.org/content/m44333/latest/?collection=col11441/latest>

Some event classes (*such as the mouse events, for example*) involve a number of different possible event types (*notification methods*) . A listener class that implements the matching interface for that event class must implement or define (*provide a body for*) all the methods declared in the interface.

Adapter classes

An intermediate set of classes, known as *Adapter* classes, is provided to prevent this from becoming burdensome. These *Adapter* classes implement the listener interfaces, and define the matching interface methods with empty methods.

A listener class can then be defined that *extends* the *Adapter* class instead of *implementing* the corresponding listener interface. With this approach, the listener class need only override those methods of interest since the requirement to define all of the interface methods has already been satisfied by the *Adapter* class.

An example

For example, in the sample program that follows, two different listener objects instantiated from two different listener classes are registered to receive all events involving the manipulation of a **Frame** object (*opening, closing, minimizing, etc.*) .

One of the listener classes *implements* the **WindowListener** interface and hence must define all six methods of that interface.

The other listener class *extends* the **WindowAdapter** class, which in turn *implements* the **WindowListener** interface. The **WindowAdapter** class defines all six methods as empty methods. Thus, this listener class can get by with overriding only two of the six methods of the interface.

4.4.2.5.5.1 Sample Program

This program named Event08 (p. 1495) was designed for simplicity. In this program, the code in each of the methods is simple. In all cases but one, the code simply displays a message indicating that the method has been called. Obviously, in order for a program to be of much value, the body of code in the methods would have to be much more substantive, or at least would have to call other methods that are more substantive.

This program illustrates the use of *Event Sources* , *Event Listeners* , and *Adapters* in the *Delegation Event Model* .

Description

Briefly, this program (p. 1495) instantiates an object that creates a user interface consisting of a simple **Frame** object. This object is an *Event Source* that notifies two different *Event Listener* objects of **Window** events.

One of the **Listener** objects *implements* the **WindowListener** interface and defines all of the methods declared in that interface. The other **Listener** object *extends* the **Adapter** class named **WindowAdapter** .

As explained earlier, the purpose of **Adapter** classes (*as used in this context*) is to implement the **Listener** interfaces and to define all of the methods with empty methods.

Classes that *extend* the **Adapter** classes can then selectively override only those methods of interest. This **Listener** object overrides only two of the methods.

(*Note that this program does not terminate and return control to the operating system. You must forcefully terminate it.*)

This program was originally tested using JDK 1.1.3 under Win95. More recently it was tested using JDK 1.7 under Windows Vista.

The output produced by running the program is presented later in this module.

4.4.2.5.5.2 Interesting Code Fragments

Listing 1 (p. 1490) shows the **main** method of the controlling class that instantiates a Graphical User Interface (GUI) object. There are more compact (*and more cryptic*) ways to accomplish this objective, but for the time being, in order to achieve clarity, I will use this approach.

Listing 1 - The main method for Event08.

```

    public class Event08 { //controlling class
    public static void main(String[] args){
        GUI gui = new GUI();//instantiate a GUIInterface object
    } //end main
} //end class Event08

```

Table 4.214

The **GUI** class is rather long, so I will break it up and discuss it in parts. This class is used

- to instantiate and display a user interface object,
- to instantiate two **Listener** objects, and
- to register those two objects for notification whenever a **Window** event occurs.

The class begins by defining its own constructor. The first interesting code in the constructor is the code to instantiate an object of type **Frame** , set its size, and give it a title, as shown in Listing 2 (p. 1490) .

Listing 2 - Beginning of the constructor.

```

    class GUI{
    public GUI(){ //constructor
        //Create a new Frame object
        Frame displayWindow = new Frame();
        displayWindow.setSize(300,200);
        displayWindow.setTitle("Copyright 1997, R.G.Baldwin");
    }

```

Table 4.215**What is a Frame?**

The JDK documentation describes a **Frame** as follows:

Description of a Frame: A **Frame** is a top-level window with a title and a border. The default layout for a frame is **BorderLayout** . (*We will learn more about layout managers later*)

Frames are capable of generating the following types of window events:

- WindowOpened
- WindowClosing
- WindowClosed
- WindowIconified
- WindowDeiconified
- WindowActivated
- WindowDeactivated.

Stated differently, a **Frame** object is the type of **GUI** object that we might refer to as a window or a form in a typical **GUI** environment.

Instantiate two Listener objects

Listing 3 (p. 1491) instantiates two **Listener** objects that will process **Window** events.

The class definitions, named **WProc1** and **WProc2**, for these two classes will follow the discussion of the **GUI** class.

*(Note that I am passing a reference to the **Frame** object to the constructor for one of these classes. There is a better (and more cryptic) way to achieve the same objective without the need to pass the reference. Again, since this program was designed for clarity, I am doing it the obvious way.)*

Listing 3 - Instantiate two Listener objects.

```
WProc1 winProcCmd1 = new WProc1(displayWindow);
WProc2 winProcCmd2 = new WProc2();
```

Table 4.216

Register the listener objects

The code in Listing 4 (p. 1491) is extremely important. This is the code by which we register the listener objects for notification of **Window** events where the **Frame** object named **displayWindow** is the source of the events.

Pay close attention to the syntax of these two statements, because you will be using this syntax often. In subsequent modules, we will dig deeper into the *Delegation Event Model* and I will teach you what is going on behind the scenes when you execute statements of this sort.

Listing 4 - Register the listener objects .

```
displayWindow.addWindowListener(winProcCmd1);
displayWindow.addWindowListener(winProcCmd2);
```

Table 4.217

Interpretation

The interpretation of the code in Listing 4 (p. 1491) is that the two listener objects named **winProcCmd1** and **winProcCmd2** are added to a list of listener objects that are to be automatically notified

- whenever an event of the **WindowEvent** class occurs
- with respect to the **Frame** object named **displayWindow** .

These listener objects are notified by calling the methods in the objects that match the specific type of the event (*open window, close window, closing window, minimize window, etc.*) .

Make the Frame visible

We wrap up the definition of our **GUI** class with the statement shown in Listing 5 (p. 1492) that causes the **Frame** object to become visible on the screen. Note that this statement also causes the **windowActivated** and **windowOpened** events to be generated. (*Current jargon would say that those events are "fired".*)

Listing 5 - Make the Frame visible.

```

        displayWindow.setVisible(true);
    }//end constructor
} //end GUI class definition

```

Table 4.218**Code for the Listener objects**

At this point, we have examined the code that will create a **Frame** object and display it on the screen. Also we have examined the code that *registers* two **Listener** objects on the **Frame** object. However, at this point, the program cannot be compiled because the classes from which the two **Listener** objects are to be instantiated have not yet been defined. That will be our next assignment.

Beginning of the class named WProc1

Listing 6 (p. 1492) begins the definition of the classes that can be used to instantiate **Listener** objects.

The first class definition that we will look at *implements* the **WindowListener** interface. This requires that all the methods declared in the interface be defined in this class. This class defines all of the methods. Each of the methods displays a descriptive message whenever it is called.

I will begin the discussion with the constructor as shown in Listing 6 (p. 1492) .

Listing 6 - Beginning of the class named WProc1.

```

class WProc1 implements WindowListener{
    Frame displayWindowRef;

    WProc1(Frame windowIn){ //constructor
        this.displayWindowRef = windowIn;
    } //end constructor
}

```

Table 4.219

*(Note that the constructor for this class requires a reference to the **Source** object to be passed as a parameter. As mentioned earlier, this is not the preferred way to accomplish our objective, but it is the most straightforward and easy to understand. That is why I elected to use it here. The code in the constructor saves a reference to the **Source** object in an instance variable named **displayWindowRef** .)*

Implementing the WindowListener interface

It is important to note that this class *implements* the **WindowListener** interface. This means that it must define all of the methods that are declared in that interface.

If you examine the complete program listing that is presented later, you will see that there is one method definition in this class definition for each of the methods that are declared in the **WindowListener** interface.

The definition of all the interface methods are very similar, so I am not going to show all of them here. However, I will show the one that requires the reference to the source object that was discussed above, which is the most complicated one of the set.

The windowClosing event handler

The methods that are declared in the listener interfaces are often referred to as *event handler* methods or *event handlers* for short. The **windowClosing** event handler method is shown in Listing 7 (p. 1493)

. As you can see, this method starts out by displaying a message. Then it calls the **dispose** method on the **Frame** object. That is the reason that a reference to the **Frame** object was required to be passed in as a parameter.

Calling the **dispose** method causes a **WindowClosed** event to be fired. (*As far as I know, that is the only way to cause a WindowClosed event to be fired.*)

Listing 7 - The windowClosing event handler.

```
public void windowClosing(WindowEvent e){
    System.out.println("WProc1 windowClosing test msg");
    displayWindowRef.dispose();//generate WindowClosed
} //end windowClosing()
```

Table 4.220

The class named WProc2

The class definition shown in Listing 8 (p. 1493) does not *implement* the **WindowListener** interface. Instead, it *extends* the **WindowAdapter** class. Therefore, it can selectively override only those methods that are of interest.

In this case, only two of the methods of the **WindowListener** interface are overridden. These overridden methods display a message whenever they are called.

Listing 8 - Definition for the class named WProc2.

```
class WProc2 extends WindowAdapter{

    public void windowIconified(WindowEvent e){
        System.out.println(
            "***** WProc2 windowIconified test msg");
    } //end windowIconified()

    public void windowDeiconified(WindowEvent e){
        System.out.println(
            "***** WProc2 windowDeiconified test msg");
    } //end windowDeiconified()

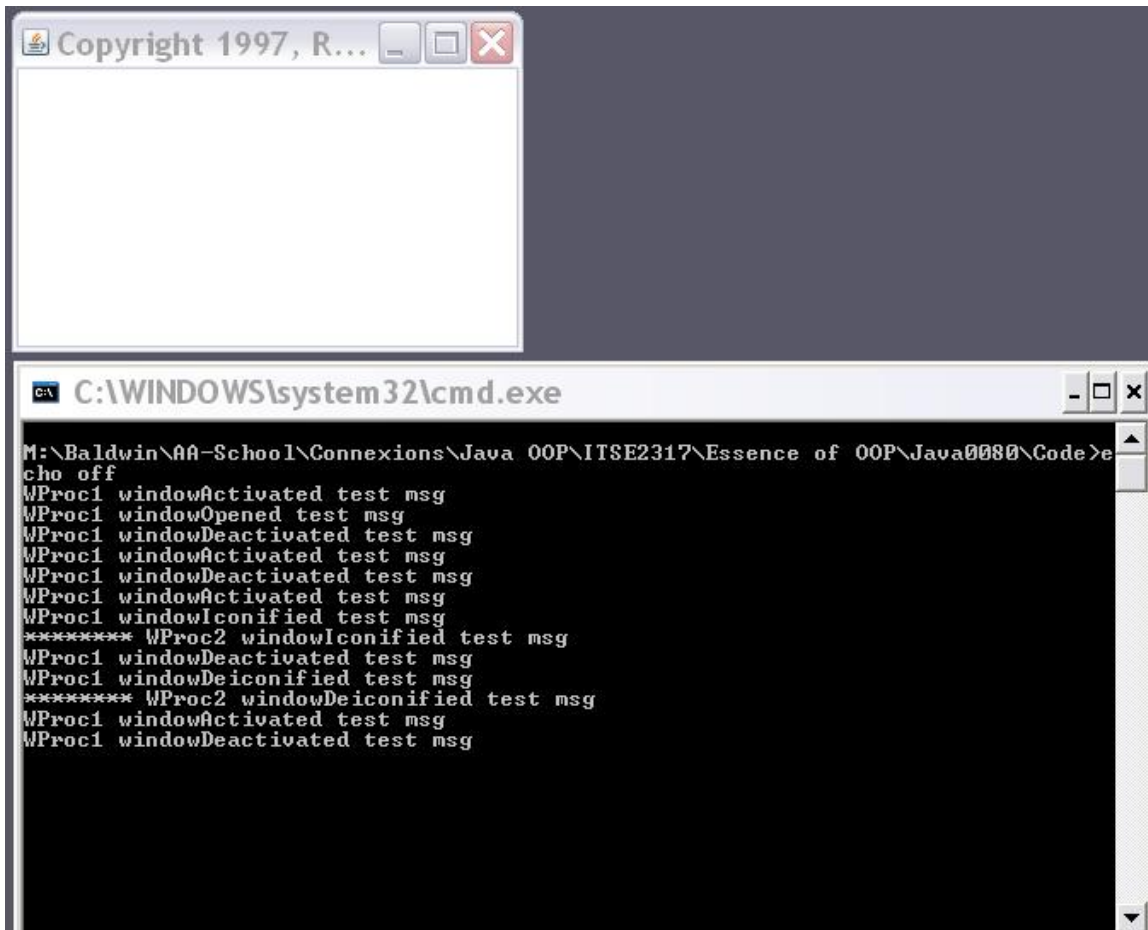

} //end class WProc2
```

Table 4.221

Program output

Figure 1 (p. 1493) shows a sample output from this program. The small **Frame** in the upper-left corner is the graphic **Frame** object. A command-line screen with text output is shown immediately below the Frame.

Figure 1 - Program output.

```

M:\Baldwin\AA-School\Connexions\Java OOP\ITSE2317\Essence of OOP\Java0080\Code>e
cho off
WProc1 windowActivated test msg
WProc1 windowOpened test msg
WProc1 windowDeactivated test msg
WProc1 windowActivated test msg
WProc1 windowDeactivated test msg
WProc1 windowActivated test msg
WProc1 windowIconified test msg
***** WProc2 windowIconified test msg
WProc1 windowDeactivated test msg
WProc1 windowDeiconified test msg
***** WProc2 windowDeiconified test msg
WProc1 windowActivated test msg
WProc1 windowDeactivated test msg

```

The text output

The output from running this program for a variety of user actions is shown below. You should be able to correlate the messages shown in the output with the event handler methods discussed above and the user actions that caused those event handlers to be called.

Text output from Event08

This program was tested using JDK 1.1.3 under Win95.

When executed, this application places a simple empty Frame object on the screen.

Starting the program produces the following output:

```

WProc1 windowActivated test msg
WProc1 windowOpened test msg

```

Pressing the minimize button on the Frame produces the following output:

```

WProc1 windowIconified test msg
***** WProc2 windowIconified test msg
WProc1 windowDeactivated test msg

```

Restoring the Frame after minimization produces the following output:

```
WProcl windowActivated test msg
WProcl windowDeiconified test msg
***** WProc2 windowDeiconified test msg
WProcl windowActivated test msg
```

Closing the Frame by pressing the X-icon in the upper right of the Frame produces the following output.

```
WProcl windowClosing test msg
WProcl windowDeactivated test msg
WProcl windowClosed test msg
```

4.4.2.5.5.3 Program Listing for Event08

A complete listing of the program is provided in Listing 9 (p. 1495) . You can view the code that was not shown above in this listing.

Listing 9 - Complete listing for Event08.

```
/*File Event08.java Copyright 1997, R.G.Baldwin
Rev 01/10/98
```

Illustrates the use of Event Sources, Event Listeners, and Adapters in the Delegation Event Model.

Briefly, this application instantiates an object that creates a user interface consisting of a simple Frame object. This object is an Event Source that notifies two different Event Listener objects of Window events.

One of the Listener objects implements the WindowListener interface and overrides all of the methods declared in that interface.

The other Listener object extends the Adapter class named WindowAdapter. The purpose of Adapter classes is to implement the Listener interfaces and to define all of the methods with empty methods. Classes that extend the Adapter classes can then selectively override only those methods of interest. This Listener object overrides only two of the methods.

Note that this application does not terminate and return control to the operating system. You must forcefully terminate it.

This program was tested using JDK 1.1.3 under Win95.

When executed, this application places a simple empty Frame object on the screen.

Starting the program produces the following output:

```
WProc1 windowActivated test msg
WProc1 windowOpened test msg
```

Pressing the minimize button on the Frame produces the following output:

```
WProc1 windowIconified test msg
***** WProc2 windowIconified test msg
WProc1 windowDeactivated test msg
```

Restoring the Frame after minimization produces the following output:

```
WProc1 windowActivated test msg
WProc1 windowDeiconified test msg
***** WProc2 windowDeiconified test msg
WProc1 windowActivated test msg
```

Closing the Frame by pressing the X-icon in the upper right of the Frame produces the following output.

```
WProc1 windowClosing test msg
WProc1 windowDeactivated test msg
WProc1 windowClosed test msg
*****/
```

```
import java.awt.*;
import java.awt.event.*;

public class Event08 {
    public static void main(String[] args){
        GUI gui = new GUI();//instantiate a GUIInterface object
    }//end main
}//end class Event08
//=====//

//The following class is used to instantiate a user
// interface object, to instantiate two Listener objects,
// and to register those two objects for notification
// whenever a Window event occurs.
class GUI{
    public GUI(){//constructor
        //Create a new Frame object
        Frame displayWindow = new Frame();
        displayWindow.setSize(300,200);
        displayWindow.setTitle("Copyright 1997, R.G.Baldwin");
```

```

//Instantiate two Listener objects that will process
// Window events
WProc1 winProcCmd1 = new WProc1(displayWindow);
WProc2 winProcCmd2 = new WProc2();

//Register the Listener objects for notification of
// Window events. This object is the Event Source.
displayWindow.addWindowListener(winProcCmd1);
displayWindow.addWindowListener(winProcCmd2);

//windowActivated and windowOpened test messages
// are produced here
displayWindow.setVisible(true);

} //end constructor
} //end class GUI definition
//=====//

//The following two classes can be used to instantiate
// Listener objects. Note that this class implements the
// WindowListener interface. This requires that all the
// methods declared in the interface be overridden in this
// class. This class overrides all of the methods and
// displays a descriptive message whenever one of the
// methods is called.
class WProc1 implements WindowListener{
//used to save a reference to the Frame object
Frame displayWindowRef;

WProc1(Frame windowIn){ //constructor
// save ref to Frame object
this.displayWindowRef = windowIn;
} //end constructor

public void windowClosed(WindowEvent e){
System.out.println("WProc1 windowClosed test msg");
} //end windowClosed()

public void windowIconified(WindowEvent e){
System.out.println("WProc1 windowIconified test msg");
} //end windowIconified()

public void windowOpened(WindowEvent e){
System.out.println("WProc1 windowOpened test msg");
} //end windowOpened()

public void windowClosing(WindowEvent e){
System.out.println("WProc1 windowClosing test msg");
displayWindowRef.dispose();//generate WindowClosed
} //end windowClosing()

```

```

public void windowDeiconified(WindowEvent e){
    System.out.println(
        "WProc1 windowDeiconified test msg");
} //end windowDeiconified()

public void windowActivated(WindowEvent e){
    System.out.println("WProc1 windowActivated test msg");
} //end windowActivated()

public void windowDeactivated(WindowEvent e){
    System.out.println(
        "WProc1 windowDeactivated test msg");
} //end windowDeactivated()
} //end class WProc1
//=====//

//This and the previous class can be used to instantiate
// Listener objects. Note that this class extends an
// Adapter class that can be used to avoid the
// requirement to define all of the methods of the
// actual Listener class named WindowListener. This class
// overrides only two of the methods declared in the
// interface. It displays a message whenever one of the
// methods is called.
class WProc2 extends WindowAdapter{

    public void windowIconified(WindowEvent e){
        System.out.println(
            "***** WProc2 windowIconified test msg");
    } //end windowIconified()

    public void windowDeiconified(WindowEvent e){
        System.out.println(
            "***** WProc2 windowDeiconified test msg");
    } //end windowDeiconified()

} //end class WProc2

```

4.4.2.5.6 More Detailed Overview of the Delegation Model

JDK 1.1 encapsulates events in a class hierarchy with the root class named `java.util.EventObject` .

The propagation of an event from a **Source** object to a **Listener** object involves calling a method on the **Listener** object and passing an object that contains encapsulated information about the event. Note that each event class may include more than one actual type of event (*as determined by the methods declared in the listener interface*) .

An event listener

A **Listener** object is an instance of a class that *implements* a specific **EventListener** interface extended from the generic `java.util.EventListener` .

An **EventListener** interface declares one or more methods that must be defined in the **Listener** class. Those methods are called by the event source in response to each specific event type handled by the interface.

The calling of these methods is the mechanism by which the **Source** notifies the **Listener** of the occurrence of an event of a specific type.

An event source

An **Event Source** is an object that "originates" or "fires" events by calling the methods of one or more **Listener** objects. The **Source** maintains a list containing a reference to all of the **Listener** objects that have *registered* to be notified of events of that class.

Registration of event listener objects

The programmer causes **Listener** objects to be added to this list using **add (EventType) Listener** method calls.

Placing references to **Listener** objects on the list is often referred to as *registering* specific **Listeners** to receive notification of specific events.

Notifying listener objects

Once the list is populated (*Listener objects are registered*), the **Source** object uses that list to notify each **Listener** of the occurrence of an event of the specified type without further effort on the part of the programmer.

Event sources and listeners

The **Event Source** is often a **GUI** component and the **Listener** is commonly an object of a class that implements the appropriate listener interface, but this is not a requirement. For example we will learn later how to cause a program to generate events without any physical involvement on the part of a user and a **GUI** component.

The **Listener** object could also be another AWT component that implements one or more **Listener** interfaces for the purpose of hooking **GUI** objects up to each other.

4.4.2.5.6.1 Event Hierarchy

As mentioned earlier, each specific event type is a member of a class of event types and these classes form a hierarchy of event classes.

Since a single event class may be used to represent more than one event type (i.e. *MouseEvent* represents *mouse up*, *mouse down*, *mouse drag*, *mouse move*, etc.) , some event classes may also contain an "id" (*unique within that class*) that maps to its specific event types.

Setter and getter methods

There are no public fields in the event classes. Rather the data in the event is encapsulated and available only through the use of appropriate *setter* and *getter* methods.

The *setter* methods only exist for attributes on an event that can be modified by a listener. If you continue with your studies in Java, you will learn that the *setter* and *getter* methods match a *design pattern* for Java Beans.

A concrete set of event classes is defined by the AWT. In addition, programmers may define their own event types by subclassing either **java.util.EventObject** or one of the AWT event classes.

4.4.2.5.6.2 Low-level vs. Semantic Events

The AWT provides two conceptual types of events:

- low-level events
- semantic events

Low-level events

A *low-level* event is one that represents a low-level input or window-system occurrence on a visual component on the screen. As of February 1997, JDK 1.1 defined the following low-level event classes:

Low-level event classes

- java.util.EventObject

- java.awt.AWTEvent
 - *java.awt.event.ComponentEvent (component resized, moved,etc.)
 - java.awt.event.FocusEvent (component got focus, lost focus)
 - java.awt.event.InputEvent
 - java.awt.event.KeyEvent (component got key-press, key-release,etc.)
 - java.awt.event.MouseEvent (component got mouse-down, mouse-move,etc.)
 - java.awt.event.ContainerEvent
 - java.awt.event.WindowEvent

As indicated earlier, some of the event classes encompass several different event types. Generally, there are corresponding **Listener** interfaces for each of the event classes, and corresponding interface methods for each of the different event types in each event class.

Semantic events

Semantic events are defined at a higher-level to encapsulate the semantics of a user interface component's model. As of February 1997, the semantic event classes defined by the JDK 1.1 version of the AWT were as follows:

Semantic event classes

- java.util.EventObject
 - java.awt.AWTEvent
 - *java.awt.event.ActionEvent ("do a command")
 - *java.awt.event.AdjustmentEvent ("value was adjusted")
 - *java.awt.event.ItemEvent ("item state has changed")
 - *java.awt.event.TextEvent ("the value of the text object changed")

A more general event type

The *semantic* events are not tied to specific screen-based component classes, but may apply across a set of components that implement a similar semantic model. For example, a **Button** object will fire an *"action"* event when it is pressed and a **List** object will fire an *"action"* event when an item is double-clicked.

Not tied to user actions

Even though the above discussion seems to tie these event classes to user actions on screen components (*because that is the norm*), you need to remember that there is nothing to prevent you from having your code generate events of these types completely independent of such user actions. For example, you can easily cause an **ActionEvent** to be generated and attributed to some component whenever a software timer expires. We will learn how to do this sort of thing in subsequent modules.

4.4.2.5.6.3 Event Listeners

An **EventListener** interface will typically have a separate method for each distinct event type that the event class represents. For example, the **FocusEventListener** interface defines two methods, **focusGained** and **focusLost**, one for each event type that the **FocusEvent** class represents.

Low-level listener interfaces

As of February 1997, the low-level listener interfaces defined by the JDK 1.1 version of the AWT were as follows:

Low-level listener interfaces

- java.util.EventListener
 - java.awt.event.ComponentListener

- java.awt.event.ContainerListener
- java.awt.event.FocusListener
- java.awt.event.KeyListener
- java.awt.event.MouseListener
- java.awt.event.MouseMotionListener
- java.awt.event.WindowListener

If you match this up with the previous list of *low-level* event classes, you will see that there is a listener interface defined for each of the "leaf" classes in the hierarchy of event classes. (*In fact, there are two different listener interfaces defined for the **MouseEvent** class. This will be discussed further at the appropriate point in time.*)

Semantic listener interfaces

As of February 1997, the semantic listener interfaces defined by the AWT were as follows:

Semantic event listener interfaces

- java.util.EventListener
 - java.awt.event.ActionListener
 - java.awt.event.AdjustmentListener
 - java.awt.event.ItemListener
 - java.awt.event.TextListener

There is a one-to-one correspondence between *semantic* listener interfaces and *semantic* event classes.

4.4.2.5.6.4 Event Sources

All AWT event sources support a *multicast* model for listeners. This means that multiple listeners can be added and removed from a single source. In other words, notification of the occurrence of the same event can be sent to one or more listener objects.

According to JDK 1.1 documentation,

"The API makes no guarantees about the order in which the events are delivered to a set of registered listeners for a given event on a given source. Additionally, any event which allows its properties to be modified (via setXXX() methods) will be explicitly copied such that each listener receives a replica of the original event. If the order in which events are delivered to listeners is a factor for your program, you should chain the listeners off a single listener which is registered on the source (the fact that the event data is encapsulated in a single object makes propagating the event extremely simple)."

Low-level event sources

As before, a distinction is drawn between *low-level* and *semantic* events. The source for *low-level* events will often be one of the visual component classes (**Button** , **Scrollbar** , etc.) because the event is bound to the actual component on the screen (*but counterfeit events can be generated*) .

As of February 1997, JDK 1.1 defined low-level listeners on the following components.

Low-level listener components

- java.awt.Component
 - addComponentListener(ComponentListener l)
 - addFocusListener(FocusListener l)
 - addKeyListener(KeyListener l)
 - addMouseListener(MouseListener l)
 - addMouseMotionListener(MouseMotionListener l)
- java.awt.Container

- addContainerListener(ContainerListener l)
- java.awt.Dialog
 - addWindowListener(WindowListener l)
- java.awt.Frame
 - addWindowListener(WindowListener l)

Must take inheritance into account

To determine all of the specific event types that can be communicated from a source object to a listener object, you must take inheritance into account.

For example, as you will see in a sample program later in this module, a source object can detect **mouse events** on a **Frame** object and notify a **MouseListener** object of the occurrence of those events even though the above list does not show a **MouseListener** on a **Frame**. This is possible because a **Frame** object indirectly extends the **Component** class, and **MouseListener** is defined for the **Component** class.

Semantic event sources

As of February 1997, JDK 1.1 defined the following semantic listeners for AWT components:

Semantic listener components

- java.awt.Button
 - addActionListener(ActionListener l)
- java.awt.Choice (implements java.awt.ItemSelectable)
 - addItemListener(ItemListener l)
- java.awt.Checkbox (implements java.awt.ItemSelectable)
 - addItemListener(ItemListener l)
- java.awt.CheckboxMenuItem (implements java.awt.ItemSelectable)
 - addItemListener(ItemListener l)
- java.awt.List (implements java.awt.ItemSelectable)
 - addActionListener(ActionListener l)
 - addItemListener(ItemListener l)
- java.awt.MenuItem
 - addActionListener(ActionListener l)
- java.awt.Scrollbar (implements java.awt.Adjustable)
 - addAdjustmentListener(AdjustmentListener l)
- java.awt.TextArea
 - addTextListener(TextListener l)
- java.awt.TextField
 - addActionListener(ActionListener l)
 - addTextListener(TextListener l)

The nature of semantic events

The nature of *semantic* event types can be inferred by noticing that in some cases, different types of components support the same type of *semantic* event. For example, four different types of components are identified in the above list that can register and service *action events*.

A single **ActionEvent** listener object could be registered to be notified of *action events* on one or more components of all of these types. Of course, it would then be necessary for the code in that event handler to determine which source was responsible for generating the event if such identification is important.

An important difference between *low level* events and *semantic* events has to do with where the classes that define those events plug into the class hierarchy. *Low level* events plug in further down the class hierarchy and inherit more methods that can be used to process the event object than is the case with *semantic* events.

4.4.2.5.6.5 Adapters

Many **EventListener** interfaces are designed to listen to multiple event classes. For example, the **MouseListener** listens to *mouse-down*, *mouse-up*, *mouse-enter*, etc. The **MouseListener** interface declares a method for each of these subtypes.

When you implement an interface, you are required to define all of the methods that are declared in the interface, even if you define them with empty methods. In some cases, the requirement to define all the methods declared in an interface can be burdensome.

For this reason (and possibly for some other reasons as well), the AWT provides a set of abstract *adapter* classes that match up with the defined interfaces. Each adapter class implements one interface and defines all of the methods declared by that interface as empty methods, thus satisfying the requirement to define all of the methods.

You can then define your listener classes by *extending* the adapter classes instead of *implementing* the listener interfaces.. This allows you the freedom to override only those methods of the interface that interest you.

Again, recall that the methods declared within an interface correspond to the individual event types contained within a corresponding event class, and the **Source** object notifies your **Listener** object of the occurrence of an event of a specific type by calling your interface method.

As of February 1997, the Adapter classes provided by the JDK 1.1 version of the AWT were as follows:

Adapter classes

- java.awt.event.ComponentAdapter
- java.awt.event.FocusAdapter
- java.awt.event.KeyAdapter
- java.awt.event.MouseAdapter
- java.awt.event.MouseMotionAdapter
- java.awt.event.WindowAdapter

4.4.2.5.6.6 Filtering for Performance

Since listeners are registered to handle specific event types, they are notified only of the occurrence of those event types and are not required to deal with event types for which they are not registered. That was not the case in JDK 1.0.2 where all events passed through a common set of event handler code whether those events were of interest or not.

This filtering of events should improve performance, especially with high frequency events, such as mouse-moves.

According to the JDK 1.1 documentation,

"All platforms should see some performance improvement from reduced event traffic, but the Solaris implementation should gain exceptional improvement since it's a network-based window system."

4.4.2.5.7 Another Sample Program

The previous program did not terminate when the user closed the window. The following program does terminate when the user closes the window by executing a `System.exit(0)` statement in the *closing* event handler..

The previous program implemented an **Event Source** object that notified two different **Listener** objects of the occurrence of an event in the **Window** class.

The following program implements an **Event Source** object that notifies one **Listener** object of the occurrence of an event in the **Window** class and notifies another **Listener** object of the occurrence of an event in the **Mouse** class.

This program implements a **MouseListener** interface on a **Frame** object, which is possible because the **Frame** class indirectly extends the **Component** class, and `addMouseListener` is defined on the **Component** class.

Program output

If you compile and execute this program, whenever you click the mouse inside the **Frame**, you should see the coordinates of the mouse pointer displayed above the mouse pointer as shown in Figure 2 (p. 1504) below.

Figure 2 - Screen output from Event09.

4.4.2.5.7.1 Event09 Interesting Code Fragments

The first interesting code fragment is the definition of the controlling class. The **main** method for this class instantiates a **GUI** object where all the real work is done. Listing 10 (p. 1505) shows the class named **Event09** including the **main** method.

Listing 10 - Beginning of the class named Event09.

```

    public class Event09 {
    public static void main(String[] args){
        GUI gui = new GUI();//instantiate a GUI
    }//end main
} //end class Event09

```

Table 4.222**The paint and repaint methods**

Various tutorial lessons on my website discuss the relationship between the **paint** method and the **repaint** method. If you are unfamiliar with that relationship, you may need to go back and review it.

In this program, we are going to override the **paint** method to make it possible for us to draw coordinate information on the screen.

In order to override the **paint** method, we need to extend the **Frame** class. By doing so, we can define our own version of the **Frame** class where we have the ability to override the **paint** method. Listing 11 (p. 1505) *extends* **Frame** into **MyFrame** and overrides the **paint** method.

Listing 11 - The class named MyFrame.

```

    class MyFrame extends Frame{
    int clickX;
    int clickY;

    public void paint(Graphics g){
        g.drawString(
            "" + clickX + ", " + clickY, clickX, clickY);
    } //end paint()
} //end class MyFrame

```

Table 4.223**Storing and using coordinate information**

For future reference, note that this class contains a couple of instance variables that will be used to store X and Y coordinate information.

The overridden version of the **paint** method causes the coordinate values stored in **clickX** and **clickY** to be displayed in the client area of the **Frame** object at the location specified by the values of those two instance variables.

The drawString method

The **drawString** method requires three parameters. The first parameter is the string to draw on the screen. The next two parameters are the coordinate values in pixels where the string is to be drawn.

As is normally the case, coordinate values are specified relative to the upper left corner of the object being drawn on. The above overridden version of the **drawString** method converts the coordinate values to a **String**, and draws that string at the location specified by the coordinate values.

The class named GUI

As before, the **GUI** class is rather long. Therefore, I will break it up and discuss it in fragments.

The first fragment that I will discuss is the constructor that begins in Listing 12 (p. 1506) . The important thing to note here is that we are not instantiating an object of type **Frame** . Instead, we are instantiating an object of type **MyFrame** that is our extended version of **Frame** .

Other than that, you should be familiar with the code in Listing 12 (p. 1506) by now.

Listing 12 - Beginning of the class named GUI.

```
class GUI {
public GUI(){//constructor
//Create a new Frame object, set size, title, etc.
MyFrame displayWindow = new MyFrame();
displayWindow.setSize(300,300);
displayWindow.setTitle("Copyright 1997, R.G.Baldwin");
displayWindow.setVisible(true);
```

Table 4.224

Register two listener objects

Listing 13 (p. 1506) uses standard syntax to instantiate and register two different **Listener** objects on the **MyFrame** object. The first is a **WindowListener** object that will terminate the program when the user closes the **MyFrame** object.

The second is a **MouseListener** object that will process *mouse events* on the **MyFrame** object.

It is typical to register listener objects as *anonymous objects* in those cases where a specific reference to the listener object is not otherwise needed. (*Don't confuse anonymous objects with anonymous classes, which is the topic of a future module.*)

Listing 13 - Register two listener objects.

```
displayWindow.addWindowListener(new WProc1());
displayWindow.addMouseListener(
new MouseProc(displayWindow));
} //end constructor
} //end class GUI definition
```

Table 4.225

Listing 13 (p. 1506) ends the definition of the **GUI** class. That brings us to the definition of **Listener** classes for the **WindowListener** and the **MouseListener** interfaces.

The MouseListener class

I will begin with the **MouseListener** class named **MouseProc** (p. 1507) . This class *extends* the **MouseAdapter** class and does not directly *implement* the *MouseListener* interface. This saves us the trouble of having to create empty methods for event types that we are not interested in.

Objects of this class that are registered on the **Source** will be notified whenever a **mousePressed()** event occurs on the **Source**. This will cause the **mousePressed** method to be called. The **mousePressed** method will display the coordinates of the mouse pointer when the mouse is pressed on the source object.

The mousePressed method

When the `mousePressed` method is called, it receives a reference to an object of type `MouseEvent` as a parameter. Different types of events encapsulate different types of information in the object that is passed as a parameter to the event handler method. This particular object contains a variety of information, including the coordinates of the mouse pointer when the event occurred.

Extract and save mouse pointer coordinates

The code in the overridden `mousePressed()` method extracts that coordinate information from the object and stores it in the instance variables named `clickX` and `clickY` of the `Source` object.

Then it calls the `repaint` method on the source object, causing the source object to be repainted on the screen. This in turn causes the overridden `paint` method discussed earlier to be called, which displays the new coordinate information on the screen in the proper location.

The class named MouseProc

Listing 14 (p. 1507) contain the definition of the `MouseProc` class, including the overridden `mousePressed` method.

Listing 14 - The class named MouseProc.

```

class MouseProc extends MouseAdapter{
    MyFrame refToWin; //save a reference to the source here

    MouseProc(MyFrame inWin){//constructor
        refToWin = inWin;//save ref to window
    }//end constructor

    public void mousePressed(MouseEvent e){
        refToWin.clickX = e.getX();
        refToWin.clickY = e.getY();

        refToWin.repaint();
    }//end mousePressed()
}//end class MouseProc

```

Table 4.226**The class named WProc1**

Finally, we come to the class that is used to instantiate a listener object that terminates the program when the user closes the `MyFrame` object (see Listing 15 (p. 1507)). You will be seeing this class over and over as you review the sample programs in upcoming modules.

Listing 15 - The class named WProc1.

```

class WProc1 extends WindowAdapter{
    public void windowClosing(WindowEvent e){
        System.exit(0);
    }//end windowClosing()
}//end class WProc1

```

Table 4.227

The **WProc1** class extends the **WindowAdapter** class and overrides the method named **windowClosing** .

The **windowClosing** method is called when the user clicks the red X in the upper right corner of Figure 2 (p. 1504) .That causes the static **exit** method of the **System** class to be called, which in turn causes the program to terminate.

4.4.2.5.7.2 Event09 Program Listing

A complete listing of the program named **Event09** is provided in Listing 16 (p. 1508) .

Listing 16 - Complete listing of Event09.

```

/*File Event09.java Copyright 1997, R.G.Baldwin
This program is designed to be compiled under JDK 1.1

Illustrates the use of Event Sources, Event Listeners, and
Adapters in the Delegation Event Model.

This program instantiates a Listener object to process
mouse events. When a mouse press occurs in a Frame object,
the program gets the coordinates and then displays those
coordinates near the point of the mouse press.

This program was tested using JDK 1.1.3 under Win95.

```

```

        System.exit(0);
    }//end windowClosing()
} //end class WProc1
//=====//

```

4.4.2.5.8 Summary

In the simplest case, you can handle events as defined in JDK 1.1 with the following steps.

4.4.2.5.8.1 Step 1

Define a **Listener** class for a specific class of events by either *implementing* the listener interface that matches that class of events, or *extending* the corresponding adapter class.

4.4.2.5.8.2 Step 2

Define or override the interface methods in the **Listener** class, for each specific event type in the event class, to implement the desired behavior of the program upon occurrence of an event.

If you *implement* the listener interface, you must define all interface methods. If instead you *extend* the corresponding adapter class, you can override only those methods that tie to event types of interest.

4.4.2.5.8.3 Step 3

Write code that instantiates objects of the **Source** class and the **Listener** class and *registers* the listener object on the source object for notification of events generated by the source object.

You can use code such as the following for registration:
`displayWindow.addMouseListener (mouseProcCmd);`
 In this code fragment,

- **displayWindow** is a reference to the object that fires the event,
- **mouseProcCmd** is the name of a reference to the listener object, and
- **addMouseListener** is the method that registers the listener object to receive mouse events from the object referred to by **displayWindow** .

This statement will cause the object named **mouseProcCmd** to be notified of all events generated by **displayWindow** which are part of the class of *mouse* events.

The notification takes the form of calling a method in the **mouseProcCmd** object where there must be a corresponding method for each specific event type in the class of *mouse* events. (*Some of those methods can be empty shells if you have no interest in some of the event types*).

4.4.2.5.8.3.1 Comments

As mentioned earlier, this is the procedure for the simplest cases. It is possible to make the situation more complicated. For example, a single **Source** object can be required to notify two or more different **Listener** objects of the occurrence of an event of the same class on a single screen object.

The **Source** object can also be required to notify two or more different **Listener** objects of the occurrence of events of two different classes on a single screen object.

A single **Listener** object can be registered to receive notification of the occurrence of events of a given class on more than one source object. In that case, it is normally necessary for the code in the **Listener** object to crack open the event object to determine which screen object was responsible for the event (*if it matters*) .

Also, the JDK 1.1 documentation indicates that it is possible to have event-style communication between objects that are not screen objects. Subsequent modules will investigate a number of these possibilities.

4.4.2.5.9 Review

The original HTML version ¹⁵⁸ of this module contains a number of review questions with answers. If interested, you can take a look at those review questions ¹⁵⁹.

4.4.2.5.10 Run the program

I encourage you to copy the code from Listing 9 (p. 1495) and Listing 16 (p. 1508). Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.2.5.11 Miscellaneous

This section contains a variety of miscellaneous information.

4.4.2.6.2 Preface

This module is one in a collection of modules designed for teaching *ITSE2317 - Java Programming (Intermediate)* at Austin Community College in Austin, TX.

(Editor's note: As you read this module, you will see that it was originally written around 1997. However, despite many improvements in Java since then, most of what was true then is still true in 2013.)

This module makes several references to my website, which is located at <http://www.dickbaldwin.com/toc.htm>¹⁶¹. A copy of the original html version of this module is available here¹⁶².

4.4.2.6.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the listings while you are reading about them.

4.4.2.6.2.1.1 Listings

- Listing 1 (p. 1516) . Beginning of the constructor for the GUI class.
- Listing 2 (p. 1516) . Complete listing of the program named SwingEvent08.
- Listing 3 (p. 1520) . The class named MyFrame.
- Listing 4 (p. 1520) . Complete listing of the program named SwingEvent09.

4.4.2.6.3 Introduction

To begin with, what is Swing?

Swing is the name given to a new set of lightweight components developed by Sun to supplement (and possibly replace) the components in the AWT. (*The general topic of lightweight components is covered in a separate module.*) With the exception of top-level containers, Swing components are developed completely using Java and don't depend on the *peer* component rendering provided by the operating system.

Swing components have several advantages over AWT components, and probably some disadvantages as well.

One of the advantages is that because the components are not rendered on the screen by the operating system, the look and feel of a component does not change as the application or applet is executed on different platforms running under different operating systems.

¹⁶¹<http://www.dickbaldwin.com/toc.htm>

¹⁶²<http://cnx.org/content/m45597/latest/Java081.htm>

Furthermore, it is possible to cause Swing components to mimic the look and feel of a specific platform no matter what platform the program is running on. This is known as *pluggable look and feel*. (A complete module is dedicated to *pluggable look and feel*.)

In any event, Swing components are here to stay, and from this point forward in these tutorial modules, we will attempt to incorporate Swing into the modules in a meaningful way.

Swing components support the JDK 1.1 Delegation Event Model¹⁶³. They do not support the JDK 1.0 event model, so if you want to use Swing components, you must program using the Delegation Event Model.

In some cases, conversion of an application or applet from AWT components to Swing components involves nothing more complex than replacing the AWT components with corresponding Swing components. For example, the Swing component that corresponds to the AWT **Button** component is the Swing **JButton** component.

In all cases that you use Swing you will need to import, or otherwise recognize the package that contains the Swing classes so that the compiler and interpreter will have access to those classes. Note that the way to do this will probably change between JDK 1.1.x and JDK 1.2, but hopefully the change won't be too great.

(*Rumor has it that Swing will be more tightly integrated into JDK 1.2 than is the case with JDK 1.1.*)

This module is designed as a follow-on to the earlier module titled "Event Handling in JDK 1.1, A First Look, Delegation Event Model"¹⁶⁴. As such, material presented in that module will not be repeated here.

The two AWT sample programs in that module were converted to Swing programs for presentation in this module using the simple substitution procedure described above. As you will see, the Swing version of one of the sample program behaves essentially the same as its AWT counterpart. The Swing version of the other sample program does not behave the same as its AWT counterpart.

So, where does that leave us? Well, fortunately, from an event handling viewpoint, Swing components operate the same as AWT components (*except that Swing provides a number of new event types*). From other viewpoints, Swing components may or may not behave the same as their AWT counterparts.

In addition, many Swing components don't have an AWT counterpart. A number of new and exciting components are included in the Swing library that don't exist in the AWT (*tooltips, progress bars, trees, etc.*).

Since this module is primarily concerned with event handling, we will pursue the Swing components from an event-handling viewpoint in this module and leave other considerations surrounding Swing components for subsequent modules. As you will see, this module will raise some interesting questions regarding the behavior of Swing components, but won't provide the answers to those questions.

4.4.2.6.4 Sample Program

The sample program in this section, named `SwingEvent08` (p. 1516), was created by replacing each instance of **Frame** in the program named **Event08**, with an instance of **JFrame**. In addition, an import declaration was added to cause the Swing classes to be accessible to the compiler and the interpreter.

(*Note that as of JDK 1.7.x, the import declaration must read `import javax.swing.*;` instead of `import com.sun.java.swing.*;` as shown in Listing 2 (p. 1516).*)

The event handling in this program is exactly the same as in **Event08** from the earlier module. If you haven't reviewed that program, and the module on the Delegation Event Model, you should probably go back and review it now.

This program illustrates the use of *Event Sources*, *Event Listeners*, and *Adapters* in the *Delegation Event Model* for Swing components.

Briefly, this application instantiates an object that creates a user interface consisting of a simple **JFrame** object. This object is an *Event Source* that notifies two different *Event Listener* objects of **Window** events.

One of the **Listener** objects *implements* the **WindowListener** interface and defines all of the methods declared in that interface.

¹⁶³<http://cnx.org/content/m44340/latest/?collection=col11441/latest>

¹⁶⁴<http://cnx.org/content/m44340/latest/?collection=col11441/latest>

The other **Listener** object *extends* the **Adapter** class named **WindowAdapter** . As explained in the earlier module, the purpose of **Adapter** classes (*as used in this context*) is to implement the **Listener** interfaces and to define all of the methods with empty methods. (*Adapter classes are viewed in a broader context in the advanced modules on the Reflection API.*)

Classes that *extend* the **Adapter** classes can then selectively override only those methods of interest. This Listener object overrides only two of the methods.

Note that this application does not terminate and return control to the operating system. You must forcefully terminate it.

This program was tested using JDK 1.1.6 and Swing 1.0.1 under Win95. (*Also, it was recently tested using JDK 1.7 running under Windows Vista after modifying the import directive mentioned above.*)

The output produced by running the program is presented in the comments at the beginning of the program listing.

4.4.2.6.4.1 Interesting Code Fragments

Listing 1 (p. 1516) provides the first and only code fragment, that I am going to show and discuss. This fragment shows the beginning of the constructor for the **GUI** class. The fragment illustrates that this program uses the **JFrame** class to instantiate a top-level container for the graphical user interface instead of a **Frame** object as in the earlier module ¹⁶⁵ .

If you compile and run this program, you will see that it behaves essentially the same as its AWT counterpart named **Event08** that was discussed extensively in the earlier module ¹⁶⁶ .

4.4.2.6.4.2 Program Listing

A complete listing of the program is provided in Listing 2 (p. 1516) .

4.4.2.6.5 Another Sample Program

This is a Swing version of the program named **Event09** from the earlier module ¹⁶⁷ .

The purpose of this program is to illustrate that in some cases, conversion of an AWT program to a Swing program isn't as simple as importing the Swing package and replacing the AWT components with their Swing counterparts.

That is what was done with this program. This program is identical to the AWT program named **Event09** except that all instances of **Frame** were replaced by **JFrame** and the Swing package was imported.

The intended behavior of this program (*go back and review **Event09** if necessary*) is to display the coordinates of the mouse pointer each time the mouse is clicked inside the client area of the **JFrame** .

Initially, this program appears to work correctly. As each new click occurs on the client area of the **JFrame** , a new pair of coordinate values is displayed. However, the previous pairs of coordinate values does not disappear as is the case with the program named **Event09** . Thus, the behavior is significantly different under JDK 1.1.6 and Swing 1.0.1 under Win95. (*The behavior is similarly different under JDK 1.7x and Windows Vista.*)

Furthermore, in some cases, while this GUI is on the screen, if focus is transferred to a different application, all of the coordinate values except the last one that was created will disappear.

It will be left as an exercise for the student to dig into the documentation on Swing in order to understand and explain this behavior.

As explained earlier, this module is concerned with event handling in Swing and this program is adequate to illustrate the use of the Delegation Event Model with Swing. We will leave the subtle behavior of the Swing components for discussion in subsequent modules.

¹⁶⁵<http://cnx.org/content/m44340/latest/?collection=col11441/latest>

¹⁶⁶<http://cnx.org/content/m44340/latest/?collection=col11441/latest>

¹⁶⁷<http://cnx.org/content/m44340/latest/?collection=col11441/latest>

If you compile and execute this program, whenever you click the mouse inside the **JFrame** , you should see the coordinates of the mouse pointer displayed above the mouse pointer.

4.4.2.6.5.1 Interesting Code Fragments

Listing 3 (p. 1520) shows the only code fragment that will be highlighted for this program in this module. This fragment illustrates how this program extends **JFrame** into a new class named **MyFrame** to make it possible to override the **paint()** method of the **JFrame** class. Recall that in the program named **Event09** , the **Frame** class was extended in a similar way.

4.4.2.6.5.2 Program Listing

A complete listing of this program is provided in Listing 4 (p. 1520) .

4.4.2.6.6 Summary

Swing provides a new set of lightweight components that can be programmed using the Delegation Event Model first introduced in JDK 1.1.

The Swing components cannot be programmed using the event model from JDK 1.0.

In some cases, all that is necessary to convert a program built around AWT components to a program built around Swing components is to import the Swing classes and replace all instances of AWT components with their Swing counterparts.

In other cases, a simple substitution as described above will not produce the same behavior.

Many of the Swing components do not have an AWT counterpart. The Swing classes contain a number of components that were never added to the AWT component library.

This module has dealt exclusively with the use of the Delegation Event Model for programming Swing components and has left some unanswered questions regarding how the behavior of Swing components does, and in some cases does not, mirror that of their AWT counterparts.

4.4.2.6.7 Run the programs

I encourage you to copy the code from Listing 2 (p. 1516) and Listing 4 (p. 1520) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.2.6.8 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

4.4.2.6.9 Listings

Listing 1 . Beginning of the constructor for the GUI class.

```
class GUI{
public GUI(){//constructor
//Create a new JFrame object
JFrame displayWindow = new JFrame();
displayWindow.setSize(300,200);
displayWindow.setTitle("Copyright 1998, R.G.Baldwin");
```

Table 4.228

Listing 2 . Complete listing of the program named SwingEvent08.

```
/*File SwingEvent08.java Copyright 1998, R.G.Baldwin
Rev 05/09/98
```

This is a Swing version of the program named Event08.

The purpose of this program is to illustrate that in many respects, programming with Swing components is no different from programming with AWT components.

Conversion of this program from AWT to Swing involved nothing more complex than using the search and replace feature of an editor to replace all instances of Frame with JFrame and to import the swing package.

Illustrates the use of Event Sources, Event Listeners, and Adapters in the Delegation Event Model for Swing components.

Briefly, this application instantiates an object which; creates a user interface consisting of a simple JFrame; object. This object is an Event Source which notifies two different Event Listener objects of Window events.

One of the Listener objects implements the WindowListener

interface and overrides all of the methods declared in;
that interface.

The other Listener object extends the Adapter class named;
WindowAdapter. The purpose of Adapter classes is to
implement the Listener interfaces and to define all of
the methods with empty methods. Classes which extend the
Adapter classes can then selectively override only those
methods of interest. This Listener object overrides only
two of the methods.

Note that this application does not terminate and return
control to the operating system. You must forcefully
terminate it.

Tested using JDK 1.1.6 and Swing 1.0.1 under Win95.

When executed, this application places a simple empty;
JFrame object on the screen.

Starting the program produces screen output similar to
the following:

```
WProc1 windowActivated test msg
Wproc1 windowOpened test msg
```

Pressing the minimize button on the JFrame produces the;
output similar to the following:

```
WProc1 windowIconified test msg
***** WProc2 windowIconified test msg
WProc1 windowDeactivated test msg
```

Restoring the JFrame after minimization produces the;
output similar to the following:

```
WProc1 windowActivated test msg
WProc1 windowDeiconified test msg
***** WProc2 windowDeiconified test msg
WProc1 windowActivated test msg
```

Closing the JFrame by pressing the X-icon in the upper;
right of the JFrame produces output similar to the;
following:

```
WProc1 windowClosing test msg
WProc1 windowDeactivated test msg
WProc1 windowClosed test msg
*****/
```

```
import java.awt.*;
```

```

import java.awt.event.*;
import com.sun.java.swing.*;

public void windowClosing(WindowEvent e){
    System.out.println("WProc1 windowClosing test msg");
    displayWindowRef.dispose();//generate WindowClosed
} //end windowClosing()

public void windowDeiconified(WindowEvent e){
    System.out.println(
        "WProc1 windowDeiconified test msg");
} //end windowDeiconified()

public void windowActivated(WindowEvent e){
    System.out.println("WProc1 windowActivated test msg");
} //end windowActivated()

public void windowDeactivated(WindowEvent e){
    System.out.println(
        "WProc1 windowDeactivated test msg");
} //end windowDeactivated()
} //end class WProc1
//=====//

//This and the previous class can be used to instantiate;
// Listener objects. Note that this class extends an;
// Adapter class which can be used to avoid the;
// requirement to define all of the methods of the
// actual Listener class named WindowListener. This class
// overrides only two of the methods declared in the;
// interface. It displays a message whenever one of the
// methods is invoked.
class WProc2 extends WindowAdapter{

    public void windowIconified(WindowEvent e){
        System.out.println(
            "***** WProc2 windowIconified test msg");
    } //end windowIconified()

```

```

public void windowDeiconified(WindowEvent e){
    System.out.println(
        "***** WProc2 windowDeiconified test msg");
} //end windowDeiconified()

} //end class WProc2

```

Listing 3 . The class named MyFrame.

```

class MyFrame extends JFrame{
    int clickX;
    int clickY;

    public void paint(Graphics g){
        g.drawString(
            "" + clickX + ", " + clickY, clickX, clickY);
    } //end paint()
} //end class MyFrame

```

Table 4.229

Listing 4 . Complete listing of the program named SwingEvent09.

```

/*File SwingEvent09.java Copyright 1998, R.G.Baldwin
Rev 5/9/98 by RGB
This is a Swing version of the program named Event09.

```

The purpose of this program is to illustrate that in some cases, conversion of an AWT program to a Swing program isn't as simple as importing the Swing package and replacing the AWT components with Swing components.

That is what was done with this program. In other words, this program is identical to the AWT program named Event09 except that all instances of Frame were replaced by JFrame and the Swing package was imported.

At the surface, the program appears to work correctly. However, as each new click occurs on the client area of the JFrame, a new pair of coordinate values is displayed, but the previous pairs of coordinate values don't disappear as is the case with the program named Event09.

Furthermore, in some cases, while this GUI is on the screen, if focus is transferred to a different application, all of the coordinate values except the last one created will disappear.

It will be left as an exercise for the student to dig into the (currently very sparse) documentation on Swing in order to understand and explain this behavior.

Illustrates the use of Event Sources, Event Listeners, and; Adapters in the Delegation Event Model for Swing.

This program instantiates a Listener object to process; mouse events. When a mouse press occurs in a JFrame object, the program gets the coordinates and then displays those coordinates near the point of the mouse press.

Tested using JDK 1.1.6 and Swing 1.0.1 under Win95.

```

*****/
import java.awt.*;
import java.awt.event.*;
import com.sun.java.swing.*;

4.4.2.7.3 Introduction

Earlier lessons discussed the sharing of a single event *source* object among two or more *listener* objects for *low-level* events.

This lesson discusses the sharing of a single listener object among two or more visual components for *low-level events* generated by any of the visual components.

The event-handling method of the listener object

- responds to each event,
- determines which visual component generated the event, and
- takes the appropriate action.

The primary issue in this type of operation boils down to determining which component generated the event.

This can be accomplished by assigning a unique name to each visual component when it is instantiated and using that name to distinguish among the visual components when an event occurs.

This approach is completely straightforward and intuitive. An improved approach to accomplishing the same objective is illustrated in some sample programs near the end of the lesson. While possibly less intuitive, the improved approach is more object-oriented and probably easier to maintain.

4.4.2.7.4 First sample program

This program illustrates the sharing of a single listener object among two different visual components of the same type.

The program detects mouse events occurring on either of two different **Frame** objects. It distinguishes between the two objects on the basis of the component name, and displays the coordinates of a mouse click on whichever object experienced the mouse click.

This program was originally tested using JDK 1.1.3 under Win95. More recently it was tested using Java 8 and Windows 7.

Note that when the program starts, the two visual components overlay one another. It is necessary to physically move one of them in order to access the other as shown in Figure 1 (p. 1525) .

Figure 1. Screen output from Event10.

4.4.2.7.4.1 Interesting code fragments

This program is really quite simple. The only new code involves cracking the event object to obtain the name of the visual component that generated the `mousePressed` event.

The `main` method instantiates an object of type `GUI` (named `gui`) which serves the purpose of providing the visual interface.

The `Frame` class is *extended* into a new class named `MyFrame` to make it possible to override the `paint` method of the class. This is necessary to display the coordinates of mouse clicks on the interior of the frame using the graphics method named `drawString` .

4.4.2.7.4.1.1 The Event Source Objects

The constructor of the `GUI` class instantiates two objects of type `MyFrame` and makes them visible. This is accomplished using code such as that shown in Listing 1 (p. 1525) .

Listing 1. An event source object.

```
MyFrame myFrame1 = new MyFrame("Frame1");
myFrame1.setVisible(true);
```

The reference variables for the two objects are named `myFrame1` and `myFrame2` .

4.4.2.7.4.1.2 Unique names

When they are instantiated, unique names (`Frame1` and `Frame2`) are given to the objects using code in the constructor (see Listing 2 (p. 1525)) for the extended `Frame` objects (the `MyFrame` class extends the `Frame` class in order to override its `paint` method).

Listing 2. Give the source objects unique names.

```

MyFrame(String name){//constructor
    setTitle("Copyright 1997, R.G.Baldwin");
    setSize(300,200);
    //Name used to distinguish between the two objects
    setName(name);
} //end constructor

```

The unique names are used later by the listener object to determine which object generated a mouse event.

4.4.2.7.4.1.3 Instantiate and register mouse listener object

The constructor in the **GUI** class also uses the code in Listing 3 (p. 1526) to instantiate a single listener object which will process low-level mouse events on either of the two visual objects.

Listing 3. Instantiate and register mouse listener object.

```

MouseProc mouseProcCmd = new MouseProc(myFrame1,myFrame2);
myFrame1.addMouseListener(mouseProcCmd);
myFrame2.addMouseListener(mouseProcCmd);

```

The first statement in Listing 3 (p. 1526) instantiates the new listener object named **mouseProcCmd** passing references to the two visual components as parameters.

The next two statements add that listener object (*register* the listener object) to a list of listener objects that are automatically notified whenever mouse events occur on the visual objects referred to as **myFrame1** and **myFrame2** , respectively.

You will recall that once the programmer causes the name of a listener object to be added to the list, no further programming effort is required to cause the notification to occur.

The notifications are carried out by invoking specific overridden instance methods of the listener object upon the occurrence of a specific types of mouse events.

The declarations for all of the methods that match up with all of the possible mouse event types are defined by the **MouseListener** interface that matches the **MouseEvent** class.

The class from which the listener object is instantiated must define, either directly or indirectly, all the methods declared in the **MouseListener** interface.

4.4.2.7.4.1.4 Instantiate and register window listener object

In addition to the *registration* of the **MouseListener** object to receive mouse events, the program also instantiates and *registers* a listener object that monitors for **Window** events and terminates the program whenever the user closes either of the two visual objects. In this case, the code in the listener object makes no attempt to distinguish between the two visual objects. The instantiation and registration code is shown in Listing 4 (p. 1526) .

Listing 4. Instantiate and register window listener object.

```

WProc1 winProcCmd1 = new WProc1();
myFrame1.addWindowListener(winProcCmd1);
myFrame2.addWindowListener(winProcCmd1);

```

4.4.2.7.4.1.5 The `MouseListener` object

Most of the programming complexity is tied up in the `MouseListener` object, and even that isn't very complicated.

The central issue for the code in the listener object is how to determine which one of several visual components generated an event.

This particular listener object only responds to `mousePressed` events, but the following information applies to all of the different types of mouse events, and probably to most or all of the low-level events as well.

The `MouseProc` (*listener*) class in this program

- extends the `MouseAdapter` class and
- overrides the `mousePressed` method that is declared in the `MouseListener` interface.

You will recall that the `MouseAdapter` class overrides all of the methods of the `MouseListener` interface with empty methods, thus freeing our code from the requirement to override all of those methods.

When the `mousePressed` method is invoked, an object of type `MouseEvent` (*known locally as `e`*) is passed in as a parameter.

4.4.2.7.4.1.6 Identify the event source

The statement in Listing 5 (p. 1527) was used in the `MouseListener` object to determine if the name of the object that generated the event is `Frame1`.

Listing 5. Identify the event source.

```
if( e.getComponent().getName().compareTo("Frame1") == 0 ){
```

If it is determined that the name of the component that generated the event is `Frame1`, code is executed to display the coordinates of the mouse pointer on the visual object named `Frame1`.

Otherwise, an `else` clause is used to display the coordinate information on the visual object named `Frame2`. (*No provisions were made for the event to have been generated by any visual objects other than these two.*)

The code to display the coordinate information is essentially the same as was discussed in a similar program in an earlier lesson, so it won't be discussed again here.

4.4.2.7.4.1.7 Cracking the `MouseEvent` object

Now let's take a look at the details of cracking the `MouseEvent` object to obtain the name of the visual component that generated the event.

The `getComponent` method is a method of the `java.awt.event.ComponentEvent` class which, according to the JDK 1.1 documentation, "*Returns the component where this event originated.*" It is returned as an object of type `Component` which is acted upon by the `getName` method in Listing 5 (p. 1527).

The `getName` method was added to the `java.awt.Component` class by JDK 1.1. This method "*Gets the name of the component*" and returns it as a `String` object. The `String` object is acted upon by the `compareTo` method in Listing 5 (p. 1527).

The `compareTo` method is a standard method of the `String` class, carried forward from JDK 1.0.2, that can be used to compare two `String` objects. It is used to determine if the name of the component matches the String "`Frame1`".

Note that it is also possible to perform tests directly on the `MouseEvent` object to match it to a component name. The procedure for doing this will be included in a future lesson.

By the way, in case you haven't noticed, the `java.awt.event` package is different from the `java.awt` package. The `java.awt.event` package was added in JDK 1.1. It can be very confusing if you drop into the `java.awt` package of the documentation when you really need to be in `java.awt.event`.

4.4.2.7.4.1.8 The WindowListener Object

This program also contains a `WindowListener` object, which terminates the program whenever the user closes either of the `Frame` objects. Except for the fact that this object is registered to receive `Window` events from either of the two `Frame` objects, it is no different from similar listeners used in an earlier sample program, and therefore, won't be discussed further here.

Note that an improved version of this program is presented at the end of this lesson. The improved version does not require the establishment of source object names, and does not require the passing of references to the constructor for the `WindowListener` in order to distinguish between the two sources. You should become familiar with the methodology used in the improved version as well as the methodology used in the following version.

4.4.2.7.4.2 Complete program listing for Event10

A complete listing of the program named `Event10` is provided in Listing 6 (p. 1528).

Listing 6. The program named `Event10`.

```

/*File Event10.java Copyright 1997, R.G.Baldwin
This program is designed to be compiled and run under
JDK 1.1

The program illustrates the sharing of a single listener
object among two different visual components of the same
type.

The program detects mouse events occurring on either of two
different Frame objects. It distinguishes between the two
objects on the basis of the component name, and displays
the coordinates of a mouse click on whichever object
experienced the mouse click.

This program was tested using JDK 1.1.3 under Win95.

Note that when the program starts, the two visual
components overlay one another. It is necessary to move
one of them in order to access the other.

//=====//

```

4.4.2.7.5 Second sample program

A single listener object can be registered to process events of a given class generated by two or more different visual objects.

Unique names can be assigned to the objects when they are instantiated.

When an event occurs, the code in the listener object can obtain the name of the visual object that generated the event and use it to distinguish among the objects.

The name of the object that generated the event can be determined using the statement shown in Listing 5 (p. 1527) where

- `e` is the local name of the object passed into the low-level event-handling method, and
- `"Frame"` is a string being tested against the component name of a visual object that may have generated the event.

4.4.2.7.5.1 Changes relative to Event10

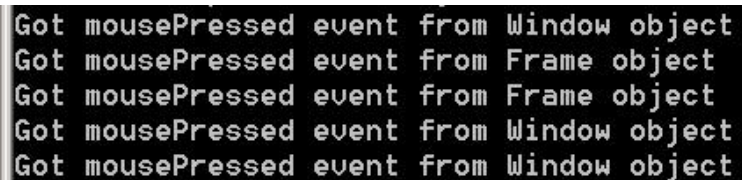

Although the program named `Event10` discussed above used two visual objects of the same type, there is no reason that the visual objects have to be of the same type, as long as all of the visual objects that share the `listener` object are capable of generating events of the event class for which the listener is designed.

This is illustrated by the program named `Event11` (see Listing 7 (p. 1532)) that modifies the program named `Event10` to use

- a visual `Frame` object and
- a visual `Window` object,

instead of two `Frame` objects.

The screen output is shown in Figure 2 (p. 1531) .

```
Got mousePressed event from Window object
Got mousePressed event from Frame object
Got mousePressed event from Frame object
Got mousePressed event from Window object
Got mousePressed event from Window object
```

Figure 2. Screen output from Event11.

Note that the **Window** object, shown as the white square in the upper left of Figure 2 (p. 1531) , doesn't have a banner that allows it to be physically moved with the mouse. Therefore, I called the **setBounds** method on both objects to separate them and to place them in a location on the screen where I could display the white **Window** object against the black background of the command-line window.

The ability to display the coordinates of mouse clicks was also removed for simplification of the program. Information about mouse clicks is displayed in the command-line window as shown in Figure 2 (p. 1531) . The operation of the program is discussed in the comments in Listing 7 (p. 1532) .

Note that an improved version of this program is also presented at the end of this lesson. The improved version does not require the establishment of source object names, and does not require the passing of references to the constructor for the Window listener in order to distinguish between the two sources. You should become familiar with the methodology used in the improved version as well as the methodology used in the version shown in Listing 7 (p. 1532) .

4.4.2.7.5.2 Complete program listing for Event11

A complete listing of the program named **Event11** is shown in Listing 7 (p. 1532) .

Listing 7. The program named Event11.

```

/*File Event11.java Copyright 1997, R.G.Baldwin
This program is designed to be compiled and run under
JDK 1.1

The program illustrates the sharing of a single listener
object between two different visual components of
different types.

The program detects mouse events occurring on either a
visual Frame object or on a visual Window object. It
distinguishes between the two objects on the basis of the
component name, and displays a message indicating which
object generated the event.

Clicking inside the Frame object but outside the Window
object produces the following message:

Got mousePressed event from Frame object

Clicking inside the Window object produces the following
message:

Got mousePressed event from Window object

Closing the Frame object produces the following message
and terminates the program:

Got windowClosing event from Frame object

These results were produced using JDK 1.1.3, running under
Windows 95.

4.4.2.7.6 Review

4.4.2.7.6.1 Question 1

Write a Java application that displays two **Frame** objects on the screen. Each object has a width of 300 pixels and a height of 200 pixels.

One object is located in the upper left-hand corner of the screen. The top left-hand corner of the other object barely touches the bottom right-hand corner of the first object as shown in Figure 3 (p. 1535) .

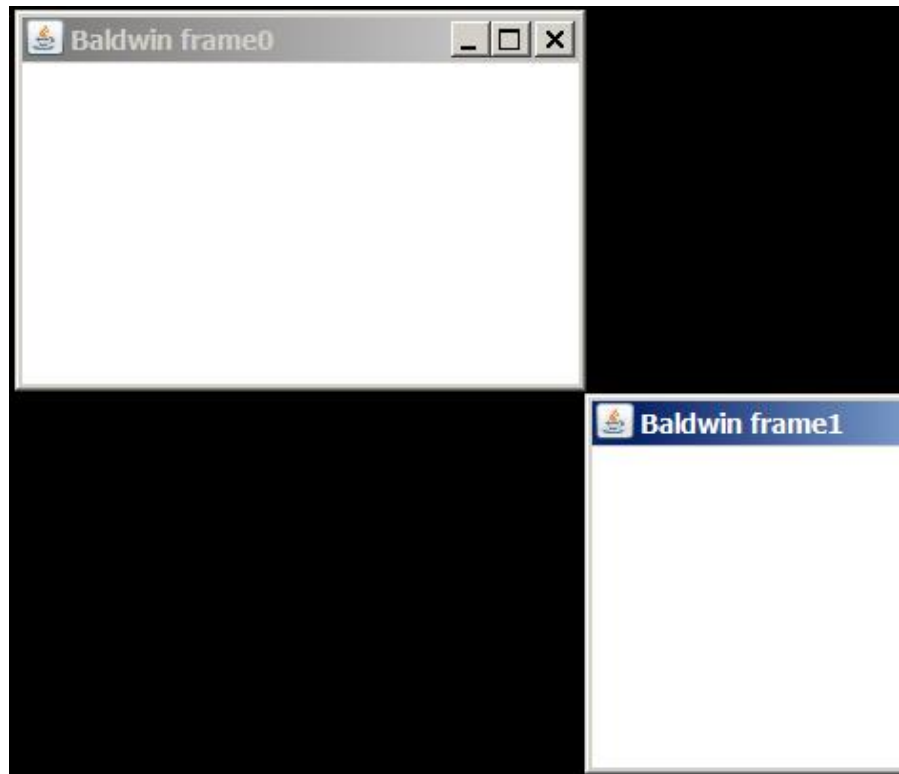

Figure 3. Screen output for Question 1.

Make your name and the name of each object appear in the banner at the top of each object. Do not assign names to the objects.

Cause the two objects to share a single listener object to respond to mouse events.

Whenever the mouse is pressed internal to either object, the coordinates of the mouse pointer are displayed near the pointer on that object with the horizontal coordinate being displayed first followed by the vertical coordinate. The two coordinate values are separated by a comma and a space.

Also cause the two objects to share a single listener object that will terminate the program whenever the user clicks the "close" button on either object.

Make certain that your application terminates and returns control to the operating system when the user clicks on the "close" button in the upper right-hand corner of the object.

Solution - See the program in Listing 8 (p. 1535) .

Listing 8. Solution to Question 1.

4.4.2.7.6.2 Question 2

Write a Java application that displays two **Frame** objects on the screen. Place a red **Panel** object in the upper-left quadrant of the second **Frame** object as shown in Figure 4 (p. 1539) . (Note that the red **Panel** is partially covered by the blue banner at the top of the **Frame** .)

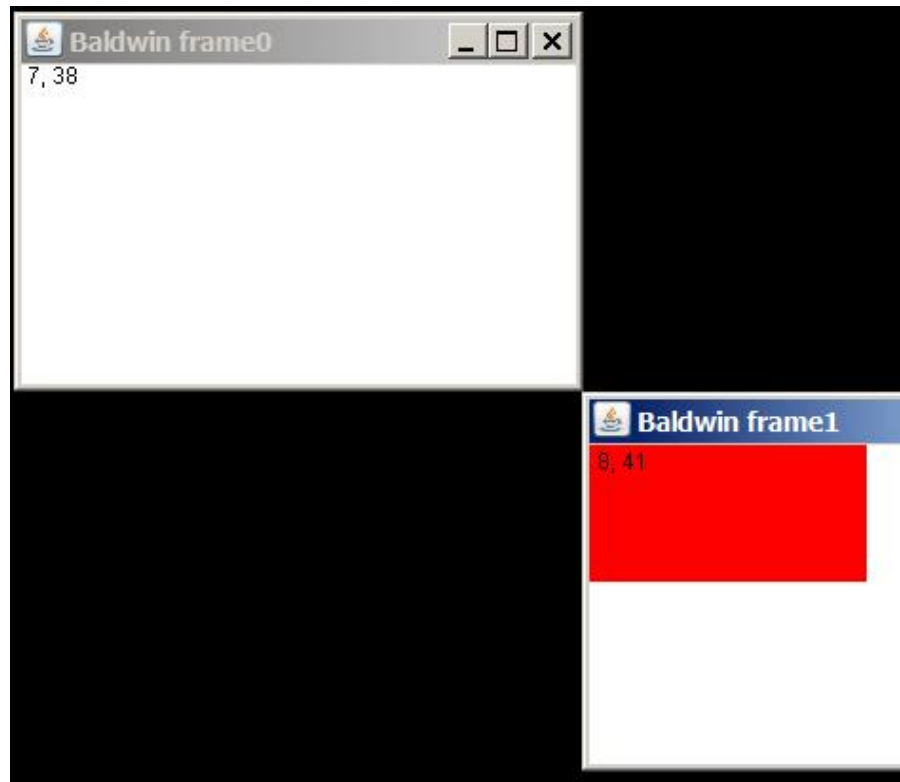

Figure 4. Screen output for Question 2.

Each **Frame** object has a width of 300 pixels and a height of 200 pixels.

One **Frame** object is located in the upper left-hand corner of the screen. The top left-hand corner of the second **Frame** object barely touches the bottom right-hand corner of the first **Frame** object.

Make your name and the name of each **Frame** object appear in the banner at the top of each **Frame** object.

Cause the first **Frame** object and the **Panel** object to share a single listener object to respond to mouse events. Do not allow the second **Frame** object (*which contains the **Panel** object*) to share the listener object for mouse events.

Whenever the mouse is pressed internal to the first **Frame** object, or on the red portion of the **Panel** object, the coordinates of the mouse pointer are displayed near the pointer on that object with the horizontal coordinate being displayed first followed by the vertical coordinate. The two coordinate values are separated by a comma and a space.

Whenever the mouse is pressed internal to the second **Frame** object, but not on the red **Panel** object, coordinate values are not displayed.

Also cause the two **Frame** objects to share a single listener object that will terminate the program whenever the user clicks the "close" button on either **Frame** object.

Make certain that your application terminates and returns control to the operating system when the user clicks on the "close" button in the upper right-hand corner of either **Frame** object.

Solution - See the program in Listing 9 (p. 1539) .

Listing 9. Solution to Question 2.

```
/*File SampProg121.java from lesson 82

4.4.2.7.6.3 Question 3

Rewrite the program named **Event10** and eliminate the requirement to pass parameters to the constructors for the event listener objects.

Solution - See the program in Listing 10 (p. 1543) .

Listing 10. Solution to Question 3.

```

/*File Event10A.java Copyright 1997, R.G.Baldwin
Rewrite the program named Event10 and eliminate the
requirement to pass parameters to the constructors for the
event Listener objects.

```

This program is designed to be compiled and run under
JDK 1.1

The program illustrates the sharing of a single listener
object among two different visual components of the same
type.

The program detects mouse events occurring on either of two
different Frame objects. It distinguishes between the two
objects and displays the coordinates of a mouse click on
whichever object experienced the mouse click.

These results were produced using JDK 1.1.3 running under
Windows 95.

```

Note that when the program starts, the two visual
components overlay one another. It is necessary to move
one of them in order to access the other.

// displays the coordinates of the mouse pointer when the
// mouse is pressed. The listener object distinguishes
// between two different visual objects and displays the
// coordinate information on the visual object which
// generated the mouse event.

class MouseProc extends MouseAdapter{
//Override the mousePressed() method to respond whenever
// the mouse is pressed on one of the frame objects.
public void mousePressed(MouseEvent e){
//Get X and Y coordinates of mouse pointer and store in
// the Frame object. Distinguish between the two
// components on the basis of the source of the event.
// Note that the following two formulations for X and Y
// can be used to produce the same results in this
// situation.
((MyFrame)e.getComponent()).xCoor = e.getX();
((MyFrame)e.getSource()).yCoor = e.getY();

//display coordinate information
e.getComponent().repaint();
} //end mousePressed()
} //end class MouseProc
//=====//

//The following listener is used to terminate the program
// when the user closes either frame object.
class WProc1 extends WindowAdapter{
public void windowClosing(WindowEvent e){
System.exit(0);
} //end windowClosing()
} //end class WProc1
//=====//

```

4.4.2.7.6.4 Question 4

Rewrite the program named **Event11** and eliminate the requirement to pass parameters to the constructor for the listener objects.

Solution - See the program in Listing 11 (p. 1546) .

Listing 11. Solution to Question 4.

```
/*File Event11A.java Copyright 1997, R.G.Baldwin
Rewrite the program named Event11 and eliminate the
requirement to pass parameters to the constructor for the
listener objects.
```

This program is designed to be compiled and run under
JDK 1.1

The program illustrates the sharing of a single listener
object between two different visual components of different
types.

The program detects mouse events occurring on either a
visual Frame object or on a visual Window object. It
distinguishes between the two objects and displays a
message indicating which object generated the event.

Clicking inside the Frame object but outside the Window
object produces the following message:

```
Got mousePressed event from Frame object
```

Clicking inside the Window object produces the following
message:

```
Got mousePressed event from Window object
```

Closing the Frame object produces the following message and
terminates the program:

```
Got windowClosing event from Frame object
```

These results were produced using JDK 1.1.3 running under
Windows 95.

```
*/
//=====//

import java.awt.*;
import java.awt.event.*;

public class Event11A {
    public static void main(String[] args){
        //instantiate a Graphical User Interface object
        GUI gui = new GUI();
    }//end main
}//end class Event11A
//=====//
```

```

//The following class is used to instantiate a graphical
// user interface object.
class GUI {
    public GUI(){//constructor
        //Create a visual Frame object
        Frame myFrame = new Frame();
        myFrame.setSize(200,300);
        myFrame.setTitle("Copyright 1997, R.G.Baldwin");
        myFrame.setVisible(true);

        //Create a visual Window object inside the Frame object
        Window myWindow = new Window(myFrame);
        myWindow.setSize(100,100);
        myWindow.setVisible(true);

        //Instantiate and register a Listener object which will
        // process mouse events on either the Frame object or
        // the Window object.
        MouseProc mouseProcCmd = new MouseProc();
        myFrame.addMouseListener(mouseProcCmd);
        myWindow.addMouseListener(mouseProcCmd);

        //Instantiate and register a Listener object which will
        // display a message and terminate the program when the
        // user closes the Frame object
        WProc1 winProcCmd1 = new WProc1();
        myFrame.addWindowListener(winProcCmd1);
    }//end constructor
} //end class GUI definition
//=====//

//This listener class monitors for mouse presses and
// displays a message when a mousePressed() event occurs on
// either the Frame object or the Window object. The
// message identifies which visual object generated the
// event. The listener object distinguishes between the two
// visual objects.

class MouseProc extends MouseAdapter{

    //Override the mousePressed() method to respond whenever
    // the mouse is pressed on one of the visual objects.
    public void mousePressed(MouseEvent e){

4.4.2.8.3 Introduction

An earlier lesson briefly discussed the differences between *low-level* events and *semantic* events as described in the JDK 1.1 documentation.

This lesson takes another look at that topic through the use of programs that apply both *low-level* event handling and *semantic* event handling to the same set of visual components. This makes it possible to compare the two types of events in a more meaningful way.

4.4.2.8.4 Overview

Although the suite of *semantic* events is generally used for different purposes than the suite of *low-level* events, from a practical programming viewpoint, there is very little difference.

The primary difference appears to reside in the nature of the event object that is passed to the event handler when an event occurs.

Using the information in the event object, *low-level* events can gain access to the specific **Component** object that generated the event.

Given a *low-level* event object, the **getComponent** method of the **java.awt.event.ComponentEvent** class will return a reference to the actual object that generated the event.

Once that reference is available, there are literally dozens of methods of the **Component** class that can be invoked on the object, such as **getLocation**, **getLocationOnScreen**, **getMaximumSize**, **getMinimumSize**, **getName**, etc.

A sample program in a previous lesson invoked the **getName** method on such an object to determine which object among several objects generated a low-level mouse event.

A sample program that we will see later in this lesson invokes some of the other available methods on such a component object.

All *low-level* event classes are subclasses of the **java.awt.event.ComponentEvent** class, so the event handlers for all *low-level* events have access to the object that generated the event.

Semantic events, on the other hand, do not subclass the **ComponentEvent** class. Rather, they subclass the superclass of **ComponentEvent** making them siblings of **ComponentEvent**.

Because they do not subclass **ComponentEvent**, the event objects passed into semantic event handlers do not provide a way to obtain a reference to the object that generated the event, and therefore cannot invoke the methods of the **Component** class on that object.

Whether this is important or not depends on your needs. For example, if you needed to determine the location of the object that generated an event, you could determine that location by processing a *low-level* event but you (*probably*) could not determine that location by processing a *semantic* event. (*Never say never unless you want some ten-year-old programming genius to prove you wrong*).

Regardless of the ability to access the object that generated the event, the name of that object is readily available to the event handlers of both *low-level* and *semantic* events.

In both cases, the name of the object is encapsulated in the event object passed as a parameter and can be extracted or tested using methods of the **String** class. Often knowing the name of the object is sufficient to accomplish the desired result.

4.4.2.8.5 Sample program for low-level events

The program named **Event 13** shown in Listing 1 (p. 1551) illustrates some of the capability of low-level events.

Listing 1. The program named Event13.

```
/*File Event13.java Copyright 1997, R.G.Baldwin  
Revised 03/09/98 to make it fit the page better.
```

This program is designed to be compiled and run
under JDK 1.1

The program demonstrates the object-manipulation capability
of low-level events.

A Button object and a TextField object are placed in a
Frame object.

A MouseListener object is instantiated and registered to
monitor for low-level mousePressed() events on all three
objects. Whenever a mousePressed() event occurs, the
Listener object obtains and displays several pieces of
information about the object that generated the event.
Although this demonstration program only obtains and
displays information as a result of mousePressed() events,
all of the methods of the Component class are available for
use at that point. Thus the code in the event handler
method could also modify some of the attributes of the
object that generated the event.

Finally, a WindowListener object is instantiated and
registered to terminate the program when the user closes
the Frame object.

Starting the program and then clicking successively on the
Button, the TextField, and the interior of the Frame
produces the following output.

```
Name = Button1  
Parent's name = Frame  
Location = java.awt.Point[x=4,y=23]  
Minimum Size = java.awt.Dimension[width=54,height=21]  
Size = java.awt.Dimension[width=192,height=21]
```

```
Name = TextField1  
Parent's name = Frame  
Location = java.awt.Point[x=4,y=275]  
Minimum Size = java.awt.Dimension[width=104,height=21]  
Size = java.awt.Dimension[width=192,height=21]
```

```
Name = Frame
No parent name available at this level
Location = java.awt.Point[x=0,y=0]
Minimum Size = java.awt.Dimension[width=112,height=69]
Size = java.awt.Dimension[width=200,height=300]
```

```
These results were produced using JDK 1.1.3, under Win95.

    }//end windowClosing()
} //end class WProc1
//=====//

```

The graphic screen output produced by this program is shown in Figure 1 (p. 1554) .

Figure 1. Graphic screen output for Event13.

A **Button** object and a **TextField** object are placed at the top and bottom of a **Frame** object.

A **MouseListener** object is instantiated and registered to monitor for low-level **mousePressed** events on all three objects.

Whenever a **mousePressed** event occurs, the listener object obtains and displays several pieces of information about the object that generated the event. Some samples of the text information produced by this program are shown in Figure 2 (p. 1554) .

Figure 2. Sample text output from Event13.

```
Name = Button1
Parent's name = Frame
Location = java.awt.Point[x=4,y=28]
Minimum Size = java.awt.Dimension[width=62,height=23]
Size = java.awt.Dimension[width=192,height=23]

Name = Frame
No parent name available at this level
Location = java.awt.Point[x=0,y=0]
Minimum Size = java.awt.Dimension[width=130,height=78]
Size = java.awt.Dimension[width=200,height=300]

Name = TextField1
Parent's name = Frame
Location = java.awt.Point[x=4,y=273]
```

```
Minimum Size = java.awt.Dimension[width=122,height=23]
Size = java.awt.Dimension[width=192,height=23]
```

Although this demonstration program only obtains and displays information as a result of **mousePressed** events, all of the methods of the **Component** class are available for use at that point. Thus the code in the event handler method could also modify some of the attributes of the object that generated the event.

Finally, a **WindowListener** object is instantiated and registered to terminate the program when the user closes the **Frame** object.

Additional information about the program is contained in the comments in Listing 1 (p. 1551) .

4.4.2.8.6 Sample program for low-level and semantic events

The sample program named **Event 12** provides both low-level and semantic event handling for the same three components as the previous program. Listing 2 (p. 1555) shows the program, which is fairly long, but it is also fairly repetitive.

Listing 2. The program named Event12.

```
/*File Event12.java Copyright 1997, R.G.Baldwin
Revised 03/09/98 to fit the page better.
Revised 02/13/04 to correct an error in the comments.
```

```
This program is designed to be compiled and run
under JDK 1.1
```

```
The program supports experimentation with low-level events
and semantic events.
```

```
A Button object and a TextField object are placed in a
Frame object.
```

```
An ActionListener object is instantiated and registered to
monitor for semantic actionPerformed()events on the Button
and the TextField.
```

```
An actionPerformed() event can be generated on a TextField
by pressing the Enter key while the TextField object has
the focus.
```

```
An actionPerformed() event can be generated by a Button by
clicking on it with the mouse.
```

```
An action event cannot be generated by a Frame object.
```

```
Whenever an actionPerformed() event occurs, the Listener
object invokes the getActionCommand() method on the object
to obtain the "command name".
```

```
The getActionCommand() method returns the "command name"
associated with the action as a String. The string is
displayed. As it turns out, the "command name" associated
```

with a Button is simply the text, caption, or label on the button. The "command name" associated with a TextField is the current text content of the TextField object.

The `ActionEvent` object passed to the `actionPerformed()` method includes the name of the component which can be used in a conditional test based on the `indexOf()` method of the `String` class to identify the component that generated the event.

Each time the `actionPerformed()` method is invoked, code in the body of the method uses the `indexOf()` method to identify the component that generated the event and displays a message identifying that component.

A `FocusListener` object is instantiated and registered to monitor for low-level `focusGained()` and `focusLost()` events on the Button and the TextField.

Whenever a `focusGained()` event occurs, a message is displayed identifying the object which gained the focus. Likewise, whenever a `focusLost()` event occurs, a message is displayed identifying the object which lost the focus. The object that gained or lost focus is identified by performing conditional tests on the `FocusEvent` object passed in as a parameter.

A `MouseListener` object is instantiated and registered to monitor for low-level `mousePressed()` events on all three objects. The Listener object differentiates among the three on the basis of the component name assigned to each object. The approach used to obtain the component name in this program uses the `indexOf()` method of the `String` class on the `MouseEvent` object. This is a somewhat less complex approach than the approach used to obtain the component name for a `mousePressed()` event in an earlier lesson. When a `mousePressed()` event occurs on any of the three visual objects, the Listener object displays a message identifying the object that generated the event.

Finally, a `WindowListener` object is instantiated and registered to terminate the program when the user closes the Frame object.

Typical outputs from the program follow:

Clicking the mouse inside the frame but outside of both the TextField and the Button produces the following output:

```
Got mousePressed event from Frame object
```

Clicking the mouse on the TextField when the Button has the focus produces the following output:

```
Got mousePressed event from TextField1 object
Got focusLost event from Button1 object
Got focusGained event from TextField1 object
```

Pressing the Enter key when the TextField has the focus produces the following output:

```
e.getActionCommand() = Initial String
Got actionPerformed event from TextField1 object
```

Clicking the mouse on the Button when the TextField has the focus produces the following output:

```
Got mousePressed event from Button1 object
Got focusLost event from TextField1 object
Got focusGained event from Button1 object
e.getActionCommand() = Click me
Got actionPerformed event from Button1 object
```

These results were produced using JDK 1.1.3 under Win95.

```

The graphic screen output for this program is shown in Figure 3 (p. 1561) .

Figure 3. Graphic screen output for Event12.

As before, a **Button** object and a **TextField** object are placed at the top and bottom respectively of a **Frame** object.

Semantic event handling is provided for **Action** events. *Low-level* event handling is provided on the same components for **mousePressed** events and **Focus** events.

4.4.2.8.6.1 Focus events

In Java, a component has the *focus* when it can accept keyboard input. There are a variety of ways by which the focus can move from one component to another. Whenever it moves, one component generates a **focusLost** event and the other component generates a **focusGained** event.

There are also some issues involving *temporary* and *permanent* changes in focus which aren't discussed here, but can be found in the JDK 1.1 documentation.

On the basis of the above description, you should see that there are many different types of components that can generate a focus event. Any component that can gain the focus can generate such an event.

There are some components such as **Button** objects and **TextField** objects that automatically gain the focus when they are clicked on by the mouse. There are other components such as **Label** objects that do not automatically gain the focus when they are clicked on by the mouse. However, even these components can gain the focus by *requesting* it. We will investigate this in more detail in a future lesson.

4.4.2.8.6.2 Action events

An action event can also be generated by many different types of components. For example, clicking a button or pressing the *Enter* key while a **TextField** object has the focus will generate an action event. The terminology derives from the notion that those user actions that generate action events are messages to the program to take the specific action indicated by the nature of the component.

For example, if a button is labeled **Exit** and it is clicked by the user, that means that the user is expecting an action that can be interpreted as *exit* in that context.

4.4.2.8.6.3 ActionListener object

In this program an **ActionListener** object is instantiated and registered to monitor for semantic **actionPerformed** events on the **Button** and the **TextField**.

When an **actionPerformed** event is generated, certain information regarding the event is encapsulated into an object that is passed to the **actionPerformed** method of the listener object. This information includes what the JDK 1.1 documentation refers to as a *command name*. This information can be accessed by the code in the method by invoking the **getActionCommand** method on the object. In this program, the *command name* is accessed and displayed on the screen.

As it turns out, the "command name" associated with a **Button** is simply the *text*, *caption*, or *label* on the button (*whatever you choose to call it*). The "command name" associated with a **TextField** is the current text content of the **TextField** object.

This information would have different uses for different components in different situations. For example, it might be used to distinguish among several buttons if the captions on the buttons were not allowed to change during the execution of the program. It might be used to extract user input from a **TextField** object.

The object of type **ActionEvent** passed to the **actionPerformed** method also includes the name of the component, which can be used in a conditional test to identify the component that generated the event. One way to do this is through use of the **indexOf** method of the **String** class to determine if a given component name is included in a specific object.

In this program, each time the **actionPerformed** method is invoked, code in the body of the method uses the **indexOf** method to identify the component that generated the event and displays a message identifying that component.

4.4.2.8.6.4 FocusListener object

A **FocusListener** object is instantiated and registered to monitor for *low-level* **focusGained** and **focusLost** events on the **Button** and the **TextField**.

Whenever a **focusGained** event occurs, a message is displayed identifying the object that gained the focus.

Likewise, whenever a **focusLost** event occurs, a message is displayed identifying the object that lost the focus.

The object that gained or lost the focus is identified by performing conditional tests on the **FocusEvent** object passed in as a parameter in the same manner that the **ActionEvent** object is used for action events.

4.4.2.8.6.5 MouseListener object

A **MouseListener** object is instantiated and registered to monitor for *low-level* **mousePressed** events on all three objects. (*Note that there are numerous other low-level mouse events that could be monitored but they were omitted in for the sake of simplicity.*)

The **MouseListener** object differentiates among the three objects (**Frame**, **Button**, and **TextField**) on the basis of the component name assigned to each object when it is instantiated.

At this point, it would probably be worthwhile to point out that JDK 1.1 Beta 3 does not require the programmer to assign unique names to components when they are instantiated. Assigned component names can be duplicated among components. (*I wonder if this is a bug? Other products such as Visual Basic and Delphi prohibit the programmer from assigning duplicate names to components.*)

If the programmer does not assign names to the components when they are instantiated, they are automatically assigned by the system, and are probably unique. The names that are automatically assigned have the format *frame0*, *frame1*, *frame2*, etc., with the main body of the name identifying the type of

component, and the digit at the end being assigned in the order in which the components are instantiated. A clever programmer should be able to find a way to obtain and make use of those names as an alternative to assigning her own names.

The approach used to obtain the component name in this program uses the `indexOf` method of the `String` class on the `MouseEvent` object. (This is a slightly less complex approach than the approach used to obtain the component name for a `mousePressed` event in an earlier lesson which went all the way back to the component object and invoked the `getName` method.)

When a `mousePressed` event occurs on any of the three visual objects, the `MouseListener` object displays a message identifying the object that generated the event.

4.4.2.8.6 WindowListener object

Finally, a `WindowListener` object is instantiated and registered to terminate the program when the user closes the `Frame` object.

4.4.2.8.6.7 More general comments about the program

The screen output for a number of different user actions is shown in the comments at the beginning of the program. This material illustrates how the `action`, `focus`, and `mousePressed` events behave during normal user interaction with the program.

In order to maintain simplicity, the response to events in this program is limited to simply displaying information. Obviously, once control is within an event handler, more significant behavior in response to an event can be programmed.

This program illustrates the fact that a single user action can cause many different types of events to be generated.

One thing to notice in particular is that since this program was not designed to manipulate the objects that generated the *low-level* events, there is very little difference in the handling of *low-level* events and *semantic* events. However, the handling would have been significantly different if the capability to manipulate the objects that generated the events had been exercised (as in the previous program).

4.4.2.8.7 Review

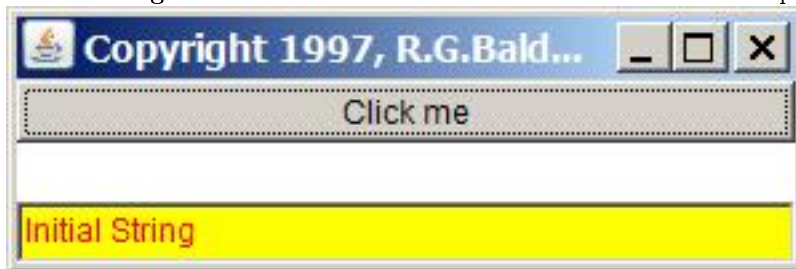

4.4.2.8.7.1 Question 1

Using only low-level events, write a Java application that originally displays a `Frame` object containing a `Button` object at the top and a `TextField` object at the bottom. Cause the `TextField` to have red letters on a yellow background as shown in Figure 4 (p. 1563).

When you click on the `TextField` object, it disappears. When you click on the `Button` object, the `TextField` object reappears.

When you click on the close button in the upper right-hand corner of the `Frame` object, the program terminates and control is properly returned to the operating system.

Figure 4. Screen output from SampProg200.

See the solution in Listing 3 (p. 1564) .

Listing 3. The solution to Question 1.

- Listing 2. (p. 1573) The main method for SwingEvent10.
- Listing 3. (p. 1573) Beginning of the class named GUI.
- Listing 4. (p. 1575) Definition of the AncestorAdded method.
- Listing 5. (p. 1576) Remaining two methods of the AncestorListener interface.
- Listing 6. (p. 1576) Complete listing of program named SwingEvent10.
- Listing 7. (p. 1580) The constructor for the GUI class.
- Listing 8. (p. 1581) Definition of the ancestor listener class.
- Listing 9. (p. 1581) Definition of the action listener class.
- Listing 10. (p. 1582) Complete listing of program named SwingEvent11.

4.4.2.9.3 Introduction

Although event handling using **Swing** components is essentially the same as event handling using **AWT** components, the **Swing** classes provide a number of new event types.

This lesson will briefly discuss the new event types (*as of Swing 1.0.1*), and will provide two sample programs that illustrate event handling with one of the new event types.

One of the sample programs will also illustrate an important new aspect of **Swing** wherein every component is also a container. In this case, we will build a pyramid of **Swing JButton** objects where each **JButton** object is contained in the one below it with the bottom **JButton** object being contained in a **JFrame** object. (See *Figure 7 (p. 1578)*.)

We will then illustrate how these **JButton** objects respond to action events and ancestor events. Action events come to us from the **AWT** whereas ancestor events are new to **Swing**.

4.4.2.9.4 New event types in Swing

One of the easiest ways to identify the new event types in **Swing** is to take a look at the listener interfaces defined in **Swing**. Another way is to take a look at the event classes defined in **Swing**.

Figure 1 (p. 1570) shows a list of the listener interfaces defined in the **com.sun.java.swing.event** package of **Swing 1.0.1**. (Note that sometime between 1997 and 2016, all Swing components were moved into the standard Java library in the **javax.swing** package.)

Figure 1. Listener interfaces defined in Swing.

- AncestorListener
- CaretListener
- CellEditorListener
- ChangeListener
- DocumentEvent
- DocumentListener
- HyperlinkListener

- CaretEvent
- ChangeEvent
- EventListenerList
- HyperlinkEvent
- InternalFrameAdapter
- InternalFrameEvent
- ListDataEvent
- ListSelectionEvent
- MenuEvent
- PopupMenuEvent
- TableColumnModelEvent
- TableModelEvent
- TreeExpansionEvent
- TreeModelEvent
- TreeSelectionEvent
- UndoableEditEvent

The two sample programs that follow illustrate the `AncestorEvent` class and the `AncestorListener` interface.

4.4.2.9.5 First sample program

The first sample program is named `SwingEvent10` . A complete listing of the program is shown in Listing 6 (p. 1576) . This program illustrates the use of the `getContentPane` method to add a `JButton` object to a `JFrame` object. It also illustrates the use of an `AncestorListener` on a `JButton` . The graphic output produced by this program is shown in Figure 3 (p. 1572) .

Figure 3. Graphic screen output for SwingEvent10.

Running the program under Java 8 and physically moving the resulting **JFrame** object on the screen produced the output shown in Figure 4 (p. 1572) .

Figure 4. Text screen output from moving the JFrame.

The program was originally tested using JDK 1.1.6 and Swing 1.0.1 under Windows 95. It was more recently tested using Java 8 and Windows 7.

Note that Figure 4 (p. 1572) shows a lot more output than was produced when the same thing was done using JDK 1.1.6 and Swing 1.0.1.

4.4.2.9.5.1 Interesting code fragments for SwingEvent10

I will discuss and explain this program in fragments. As mentioned earlier, a complete listing of this program is shown in Listing 6 (p. 1576) . Listing 1 (p. 1573) shows the import declarations required to import the **Swing** packages. (Note that this is different than was the case with JDK 1.1.6 and Swing 1.0.1. The old versions of the import directives are shown as comments in Listing 1 (p. 1573) .)

import javax.swing.event.*;//JDK 1.2 version

```

The **main** method in the controlling class is simple, but we will include it in Listing 2 (p. 1573) for continuity.

Listing 2. The main method for SwingEvent10.

```

public class SwingEvent10 {
    public static void main(String[] args){
        GUI gui = new GUI();//instantiate a GUI
    }//end main
}//end class SwingEvent10

```

That brings us to the class named **GUI** from which we will instantiate our graphical user interface object and display it on the screen. The class named **GUI** begins in Listing 3 (p. 1573) .

Listing 3. Beginning of the class named GUI.

```

class GUI {
    public GUI(){//constructor
        //Create a new JFrame object, set size, title, etc.
        JFrame displayWindow = new JFrame();
        displayWindow.setSize(300,300);
    }
}

```

```

displayWindow.setTitle("Copyright 1998, R.G.Baldwin");
//Add window listener to terminate the program
displayWindow.addWindowListener(new WProcl());

//Create a JButton object
JButton theButton = new JButton("Button");

//Register an AncestorListener object on the JButton
theButton.addAncestorListener(new MyAncestorListener());

//Add the JButton to the JFrame using content pane
displayWindow.getContentPane().add(theButton);

System.out.println("Make JFrame visible");
displayWindow.setVisible(true);
} //end constructor

```

As you can see in Listing 3 (p. 1573), the constructor for our **GUI** object is pretty straightforward.

We begin by instantiating a **Swing** object of type **JFrame**, setting its size, giving it a title, etc.

We also add a **WindowListener** to terminate the program when the user closes the **JFrame** object. (There is an alternative and possibly better way to accomplish that in Java 8 than was the case in 1997. See the *setDefaultCloseOperation* method in the documentation for the **JFrame** class.)

Then we instantiate a **Swing** object of type **JButton** and register an **AncestorListener** object on the button. We will discuss the class from which the listener was instantiated shortly.

After this, we add the **JButton** object to the **JFrame** object named **displayWindow** by first invoking the **getContentPane** method and then invoking the **add** method on the content pane.

Finally, we display a message and make the **JFrame** object visible. That concludes the constructor.

Now what about the **getContentPane** method. This is something that doesn't exist in the **AWT**.

In the **AWT**, we add components to, and otherwise manipulate the client area of a **Frame** object directly. However, in **Swing**, some "panes" are automatically placed in the client area of a **JFrame** object, and we add components to, and otherwise manipulate those panes instead of manipulating the client area of the **JFrame** object directly.

Rather than to try to explain this in my own words, I am simply going to provide a quotation from the JavaSoft documentation for the **JFrame** object, Swing, Version 1.0.1 in Figure 5 (p. 1574). Note that the wording in Figure 5 (p. 1574) is the copyrighted property of JavaSoft.

Figure 5. Information regarding the content pane.

```
public class JFrame extends Frame implements WindowConstants, Accessible, RootPaneContainer
```

An extended version of java.awt.Frame that adds support for interposing input and painting behavior in front of the frames children (see glassPane), support for special children that are managed by a LayeredPane (see rootPane) and for Swing MenuBars.

The JFrame class is slightly incompatible with java.awt.Frame. JFrame contains a JRootPane as it's only child. The contentPane should be the parent of any children of the JFrame. This is different than java.awt.Frame, e.g. to add a child to an AWT Frame you'd write:

```
frame.add(child);
```

However using JFrame you need to add the child to the JFrame,s contentPane instead:

```
frame.getContentPane().add(child);
```

The same is true for setting LayoutManagers, removing components, listing children, etc. All these methods should normally be sent to the contentPane instead of the JFrame itself. The contentPane

will always be non-null. Attempting to set it to null will cause the `JFrame` to throw an exception. The default `ContentPane` will have a `BorderLayout` manager set on it.

Please see the `JRootPane` documentation for a complete description of the `ContentPane`, `glassPane`, and `layeredPane` properties.

For the time being, and for this simple example, this all boils down to a requirement to insert the method call

```
getContentPane()
```

between the reference to the `JFrame` object and calls to `add`, `setLayout`, etc. For more complex programs, the ramifications could be more significant.

Our `GUI` class has two inner classes. One of those is a `WindowListener` class that is used to terminate the program when the user closes the `JFrame` object. It is so simple and so common that I'm not going to show it here. You can see it in the complete listing of the program in Listing 6 (p. 1576) if you are interested.

The second inner class (*and these could just as well be implemented as top-level classes instead of inner classes*) is used to instantiate an `AncestorListener` object to be registered on the `JButton` object.

This is a little more interesting. The `AncestorListener` interface declares three methods, and as far as I know there is no adapter for this interface. Therefore, our class that implements the interface must define all three methods.

A brief description of each of the three methods is provided in Figure 6 (p. 1575).

Figure 6. Methods of the `AncestorListener` interface.

- **ancestorAdded(AncestorEvent)** – Called when the source or one of its ancestors is made visible either by `setVisible(true)` being called or by its being added to the component hierarchy.
- **ancestorMoved(AncestorEvent)** – Called when either the source or one of its ancestors is moved.
- **ancestorRemoved(AncestorEvent)** – Called when the source or one of its ancestors is made invisible either by `setVisible(false)` being called or by its being remove from the component hierarchy.

As you can see, whenever one of the methods is called, an object of type `AncestorEvent` is passed as a parameter. As usual, it is possible to invoke the methods of the `AncestorEvent` class and the classes extended by that class to learn more about the event.

We will define all three of the interface methods (*as required*) in our class definition. The code fragment in Listing 4 (p. 1575) shows the definition of the `ancestorAdded` method.

Listing 4. Definition of the `AncestorAdded` method.

```
class MyAncestorListener implements AncestorListener{
    //Define three methods declared in AncestorListener
    // interface.

    public void ancestorAdded(AncestorEvent e){
        System.out.println("ancestorAdded method invoked");
        System.out.println("Event source: " + e.getSource());
        System.out.println("Ancestor: " + e.getAncestor());
        System.out.println("Parent: " + e.getAncestorParent());
        System.out.println("Component: " + e.getComponent());
        System.out.println("ID value: " + e.getID());
    }//end ancestorAdded()
}
```

When this method is called, it invokes five different methods of the incoming **AncestorEvent** object and displays the material returned from those methods. The output from invoking these methods was shown earlier in Figure 4 (p. 1572) .

The final code fragment for this program in Listing 5 (p. 1576) shows the definitions of the other two methods of the **AncestorListener** interface.

Listing 5. Remaining two methods of the AncestorListener interface.

```
public void ancestorRemoved(AncestorEvent e){
    System.out.println("ancestorRemoved method");
} //end ancestorRemoved()

public void ancestorMoved(AncestorEvent e){
    System.out.println("ancestorMoved method");
} //end ancestorMoved
} //end class MyAncestorListener
//.....//
} //end class GUI definition
```

If you compile and run this program and observe the output as the program runs, you will see that the **ancestorAdded** method and the **ancestorMoved** method are both called when the **JFrame** object is made visible.

Following this, whenever the **JFrame** object is moved on the screen, the **ancestorMoved** method will be called.

Iconifying and then deiconifying the **JFrame** object will also cause the **ancestorMoved** method to be called.

4.4.2.9.5.2 Program listing for SwingEvent10

Listing 6 (p. 1576) contains a complete listing for the program named **SwingEvent10** .

Listing 6. Complete listing of program named SwingEvent10.

```
/*File SwingEvent10.java Copyright 1998, R.G.Baldwin
Code updated 07/10/16 to be Java 8 compatible.
Rev 1/12/99 to be JDK 1.2 Swing compatible

Illustrates use of getContentPane() to add a JButton to
a JFrame.

Illustrates use of AncestorListener on a JButton.

Running the program and moving the resulting JFrame on the
screen produced the following output. Note that line breaks
were manually added to this presentation to make the lines
fit in this format. Note that these outputs don't seem to
provide a good match for the descriptions and names of the
methods in the JavaSoft documentation.

Make JFrame visible
ancestorAdded method invoked
```

```

Event source: com.sun.java.swing.JButton[,0,0,0x0,
            invalid,layout=com.sun.java.swing.OverlayLayout]
Ancestor: com.sun.java.swing.JButton[,0,0,0x0,
            invalid,layout=com.sun.java.swing.OverlayLayout]
Parent: com.sun.java.swing.JPanel[null.contentPane,0,0,0x0,
            invalid,layout=com.sun.java.swing.JRootPane$1]
Component: com.sun.java.swing.JButton[,0,0,0x0,
            invalid,layout=com.sun.java.swing.OverlayLayout]
ID value: 1
ancestorMoved method
ancestorMoved method

```

Tested using JDK 1.1.6 and Swing 1.0.1 under Win95.

```

//.....//
}//end class GUI definition
//=====//

```

4.4.2.9.6 Second sample program

This program named **SwingEvent11** further illustrates the use of an **AncestorListener** on a **JButton**. The graphic screen output for this program is shown in Figure 7 (p. 1578).

Figure 7. Graphic screen output for SwingEvent11.

More importantly, this program illustrates the very important fact that **JButton** objects are containers that can contain other objects including other **JButton** objects.

This program stacks three **JButton** objects on top of one another with the stack of three **JButton** objects being placed on a **JFrame** object. **ActionListener** objects are registered on each of the buttons to trap an **actionPerformed** event when the button is clicked and to display the source of the event.

Running the program using Java 8 and carefully clicking each of the three buttons in succession from the top of the stack to the bottom of the stack, and then moving the **JFrame** object on the screen produces the output shown in Figure 8 (p. 1579) .

Figure 8. Text output from clicking buttons.

```
Make JFrame visible

```

```

Event source: Second Button
In ancestorMoved method
Event source: Third Button
In ancestorMoved method
Event source: First Button
In ancestorMoved method
Event source: Second Button
In ancestorMoved method
Event source: Third Button

```

This program was originally tested using JDK 1.1.6 and Swing 1.0.1 under Windows 95. More recently it was tested using Java 8 under Windows 7. As mentioned above, the output shown in Figure 8 (p. 1579) was produced using Java 8.

4.4.2.9.6.1 Interesting code fragments for SwingEvent11

As before, I will discuss and explain this program using code fragments. A complete listing of the program is shown in Listing 10 (p. 1582) .

The controlling class and the **main** method for this program is the same as the previous program, so I won't discuss it here.

The **GUI** class is shown in Listing 7 (p. 1580) .

Listing 7. The constructor for the GUI class.

```

class GUI {
    public GUI(){//constructor
        //...snip

        displayWindow.getContentPane().setLayout(
            new FlowLayout());
        //...snip

        JButton firstButton = new JButton("First Button");
        JButton secondButton = new JButton("Second Button");
        JButton thirdButton = new JButton("Third Button");

        //Stack the three JButton objects on top of one
        // another.
        firstButton.add(secondButton);
        secondButton.add(thirdButton);

        //Register an AncestorListener object on each JButton
        firstButton.addAncestorListener(
            new MyAncestorListener());
        secondButton.addAncestorListener(
            new MyAncestorListener());
        thirdButton.addAncestorListener(
            new MyAncestorListener());

        //Register an ActionListener object on each JButton
        firstButton.addActionListener(new MyActionListener());
    }
}

```

```

secondButton.addActionListener(new MyActionListener());
thirdButton.addActionListener(new MyActionListener());

//...snip

} //end constructor

```

Much of the code in the constructor for the **GUI** class is also the same as in the previous program so I deleted it from Listing 7 (p. 1580) for brevity.

Note the use of **getContentPane** when setting the layout manager as described earlier.

Three **JButton** objects are instantiated. Then the three buttons are stacked by adding **secondButton** to **firstButton** , and by adding **thirdButton** to **secondButton** .

An **AncestorListener** object is registered on all three of the buttons and then an **ActionListener** object is registered on all three of the buttons.

The remainder of the constructor is the same as before and was deleted for brevity.

The ancestor listener class is very similar to the previous version, so the definition for only one of the methods is shown in Listing 8 (p. 1581) .

Listing 8. Definition of the ancestor listener class.

```

class MyAncestorListener implements AncestorListener{
    public void ancestorAdded(AncestorEvent e){
        System.out.println("In ancestorAdded method");
        System.out.println("Event source: " +
            ((JButton)e.getSource()).getActionCommand());
    } //end ancestorAdded()

    //...snip
} //end class MyAncestorListener

```

Note the requirement for downcasting in this version of the method. This is because invocation of the **getSource** method returns an object of type **Object** and it must be downcast to type **JButton** to be useful.

Listing 9 (p. 1581) shows the **ActionListener** class that traps action events on the buttons when they are clicked and presents appropriate output on the screen.

Listing 9. Definition of the action listener class.

```

class MyActionListener implements ActionListener{
    public void actionPerformed(ActionEvent e){
        System.out.println("In actionPerformed method");
        System.out.println("Event source: " +
            ((JButton)e.getSource()).getActionCommand());
    } //end actionPerformed()
} //end class MyActionListener

```

4.4.2.9.6.2 Program listing for SwingEvent11

Listing 10 (p. 1582) contains a complete listing of the program named **SwingEvent11** .

Listing 10. Complete listing of program named SwingEvent11.

```
/*File SwingEvent11.java Copyright 1998, R.G.Baldwin  
Code updated 7/10/16 for Java 8 compatibility.
```

```
Revised 1.12/98 for JDK 1.2 Swing compatibility.
```

```
Further illustrates use of AncestorListener on a JButton.  
Also see SwingEvent10.java.
```

```
Illustrates that JButton objects are containers that  
can contain other JButton objects.
```

```
This program stacks three JButton objects on top of one  
another with the stack of three JButton objects being  
placed on a JFrame object.
```

```
Running the program and carefully clicking each of the  
three buttons in succession from the top of the stack to  
the bottom of the stack, and then moving the JFrame object  
on the screen produces the following output. Note that  
some blank lines were manually inserted to make it easier  
to follow this material.
```

```
Make JFrame visible

4.4.2.10.3 Introduction

Previous lessons involving Swing told you that when you add a component to a `JFrame` object, unlike with the `AWT`, you must use statements similar to the following.

```
myJFrameObject.getContentPane().add(myChildComponent);
```

As you have probably suspected, there is a lot more to it than just inserting `getContentPane()` between the object reference and the `add` method.

The purpose of this lesson is to help you understand why you need to use `getContentPane` or some similar method call to add components to a `JFrame` object, remove components from a `JFrame` object, or set the layout for a `JFrame` object.

Note that this also applies to container objects of type `JInternalFrame` and `JDialog` as well.

4.4.2.10.4 General discussion

When programming with the `AWT`, you can place a `Panel` object in a `Frame` object and place other components on the `Panel` object if you wish, or you can simply place other components directly on the viewable area of the `Frame` object.

The viewable area of `Frame` or a `JFrame` is the *bounds* minus the *insets*. Insets are used to account for the space covered by the borders and the values of the insets on all four sides are available by invoking the method named `getInsets()` on the object.

However, you cannot place components directly on the viewable area of a `JFrame` object.

An object of type `JRootPane` is automatically placed in the `JFrame` completely covering the viewable area of the `JFrame` object.

One way or another, if you want to place components in the `JFrame`, you must deal with the `JRootPane` object.

One way to deal with it, and this is the way that you will find recommended in many current discussions on the subject, is simply ignore the technical details and insert a call to the `getContentPane` method between the reference to the `JFrame` and the `add` method.

My preference is to first understand why you need to do that, and in those cases where that is the appropriate thing to do, go ahead and do it.

In those cases where invoking `getContentPane` is not the most appropriate thing to do, do the thing that is most appropriate.

Note: You will find much discussion in this lesson about some components being on top of other components. These discussions apply only to Swing lightweight components. Remember that heavyweight (*AWT*) components are always on top of lightweight (*Swing*) components regardless of what the text in this lesson may say.

4.4.2.10.4.1 Synopsis

JRootPane is a container. The instance of **JRootPane** that is automatically placed in a **JFrame** object contains at least two other objects.

- An object of type **JLayeredPane** that we will refer to simply as the *layeredPane* .
- An object of type **JPanel** that we will refer to simply as the *glassPane* .

There is also an optional *menuBar* object that comes in here somewhere, but since it is not essential for understanding what is going on at this level, I have elected to defer the discussion until the discussion on Swing menus.

The *layeredPane* and the *glassPane* also fill the viewable area of the **JFrame** object. The *glassPane* is on top of the *layeredPane* , and as the name might imply, it is *normally* transparent.

Components on the *layeredPane* are visible through the *glassPane* . Mouse events are capable of penetrating the *glassPane* and reaching components on the *layeredPane* as long as the *glassPane* is transparent.

The *layeredPane* contains another component of type **JPanel** that we will refer to as the *contentPane* . This is the same pane that we are dealing with when we invoke the **getContentPane** method on the **JFrame** object.

The *layeredPane* has a very interesting behavior.

In the same sense that we can add components to the *contentPane* , we can also add components to the *layeredPane* .

When we add components to the *contentPane* , they are all added at the same layer and components added first are painted on top of components added later.

However, when we add components to the *layeredPane* , we can specify the layer number that we want the component to be drawn on.

Components drawn on layers with high (*algebraically signed*) numbers are painted on top of components on layers with smaller (*algebraically signed*) numbers.

Large negative numbers are smaller than small positive numbers in this case with the smallest allowable layer number being -29999.

In addition, a variety of methods are available to move components from one layer to another at runtime. This gives us the ability to not only control the order in which components are painted initially, but also to modify that order later at runtime.

This layering concept is a much more powerful approach than simply inserting **getContentPane** between the reference to the **JFrame** object and the invocation of the **add** method.

Layering has a long history of beneficial results in computer graphics such as Computer Aided Design and game programming.

So, where does the *contentPane* object that belongs to the *layeredPane* fit into this?

Components on the *contentPane* are painted behind all components that may be added directly to the *layeredPane* . In fact, the layer position for the *contentPane* is effectively layer number -30000. The smallest layer number that can be used to place a component directly on a layer is -29999. (*We will place one there in our sample program later.*)

4.4.2.10.4.2 More detailed discussion

As mentioned earlier, a `JRootPane` contains a `glassPane` (`JPanel`) and a `layeredPane` (`JLayeredPane`). The `layeredPane` contains an optional `menuBar` (`JMenuBar`) and a `contentPane` (`JPanel`). The `menuBar` component is optional and may or may exist at any given time. The `layeredPane` , `contentPane` , and `glassPane` will always be available.

The syntax for dealing with these panes is somewhat different from what you are accustomed to. For example, the typical syntax for adding a component to a container would look something like the following:

```
parentContainer.add(childObject);
```

However, the required syntax for dealing with these panes is more like one of the following:

```
myJFrameObject.getContentPane().add(myChildComponent);

myJFrameObject.getLayeredPane().add(
    myChildComponent, new Integer(5));
```

The first statement above adds a component to the `contentPane` . The second statement adds a component to layer number 5 of the `layeredPane` .

The same concepts apply when removing components, setting layout managers, etc.

The `contentPane` has a `BorderLayout` manager by default. The `layeredPane` has no layout manager (`null`) by default as you will see in the sample program that follows later in this lesson.

If a `JMenuBar` component is set on the `JRootPane` , it is positioned along the upper edge of the frame. The `contentPane` is adjusted in location and size to fill the remaining area.

If you examine the documentation for `JLayeredPane` , you will see that the class has the following fields which are all `public static final Integer` symbolic constants.

- `DEFAULT_LAYER` - Object defining the Default layer. Equivalent to `new Integer(0)`.
- `PALETTE_LAYER` - Object defining the Palette layer. Equivalent to `new Integer(100)`.
- `MODAL_LAYER` - Object defining the Modal layer. Equivalent to `new Integer(200)`.
- `POPUP_LAYER` - Object defining the Popup layer. Equivalent to `new Integer(300)`.
- `DRAG_LAYER` - Object defining the Drag layer. Equivalent to `new Integer(400)`.
- `FRAME_CONTENT_LAYER` - Object defining the Frame Content layer. This layer is normally only used to position the `contentPane` and `menuBar` components of `JFrame` . Equivalent to `new Integer(-30000)`.

The `JMenuBar` and the `contentPane` are added to the `layeredPane` component at the following layer (-30000):

```
JLayeredPane.FRAME_CONTENT_LAYER
```

As mentioned earlier, the `layeredPane` object is an instance of the `JLayeredPane` class. The purpose of this object is to be the parent of all children of the `JRootPane`.

Also, as mentioned earlier, this object provides the ability to add components at several layers. This is very useful when working with popup menus, dialog boxes, during dragging, or for any other situation in which you might want to separate graphic objects onto different layers for display purposes.

Also as indicated earlier, the `glassPane` is always added as the first child of the `JRootPane`. This causes the `glassPane` to always be on the top of the stack. By default, the `glassPane` is not visible and is transparent. Thus, mouse events can normally penetrate the `glassPane` and impinge upon the components below it.

It is theoretically possible to draw components on the `glassPane` (*although I haven't been able to purposely do it as of 5/12/98*). When this is done, those components shadow the components below them preventing mouse events from impinging on the components down below.

Components drawn on the `glassPane` will always be above all other lightweight components in the stacking order of components (*but not over top of heavyweight components*). Thus, the `glassPane` can be used to assure that such components as popup menus and tool tips are always on top of the other components on the screen.

As mentioned earlier, by default, the `glassPane` is not visible. Developers should use `setVisible` on the `glassPane` to control when the `glassPane` displays over the other children.

The layout manager used by `JRootPane` insures that the following is true:

- The `glassPane`, if present, fills the entire viewable area of the `JRootPane` (bounds - insets).
- The `layeredPane` fills the entire viewable area of the `JRootPane`. (bounds - insets)
- The `menuBar` is positioned at the upper edge of the `layeredPane` ().
- The `contentPane` fills the entire viewable area, minus the `MenuBar`, if present.

If you replace the layout manager of the `JRootPane` with a different layout manager, you are responsible for managing all of those views.

So now we know that the `JRootPane` object contains an object of type `JLayeredPane`. While `JLayeredPane` manages its list of children like a `Container`, it also allows for the definition of several layers within itself.

Children in the same layer are managed exactly like the normal `Container` object. However, children in higher layers display above the children in lower layers. Each layer has a distinct integer number.

Apparently each Swing `Component` has a layer attribute (*but I haven't been able to find out anything about it other than as described below*).

There are at least three ways to set the layer attribute on a `Component`:

- Passing an Integer object with a literal integer value during the add call: `layeredPane.add(child,new Integer(10));`
- Passing one of the symbolic constants mentioned earlier during the add call: `layeredPane.add(child,JLayeredPane.DEFAULT_LAYER)`
- Calling the following set method on the `JLayeredPane` that will be the parent of the component and passing the name of the component and an `int` that specifies the layer number: `layeredPaneParent.setLayer(child,10)`

In this third case, the layer should be set before adding the child to the parent.

Layers with higher numbers display on top of layers with lower numbers.

Higher and lower in this case includes the algebraic sign of the layer. For example, a large negative number is a lower layer than a small positive number.

These layers are simply a logical construct and layout managers will affect all child components without regard for layer settings. Therefore, to take advantage of this layering capability, you may need to design your own layout manager or use absolute layout (*null layout manager*).

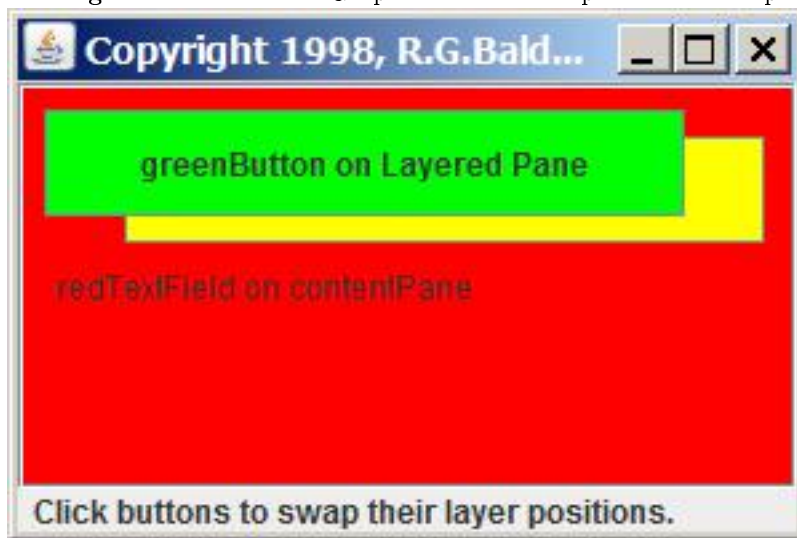

We will see some examples in the sample program that follows.

4.4.2.10.5 Sample program

The primary purpose of this program is to illustrate the use of both the *contentPane* and the *layeredPane*.

The program places a **JFrame** object on the screen as the primary GUI as shown in Figure 1 (p. 1591).

Figure 1. Graphic screen output for the program named SwingPane01.

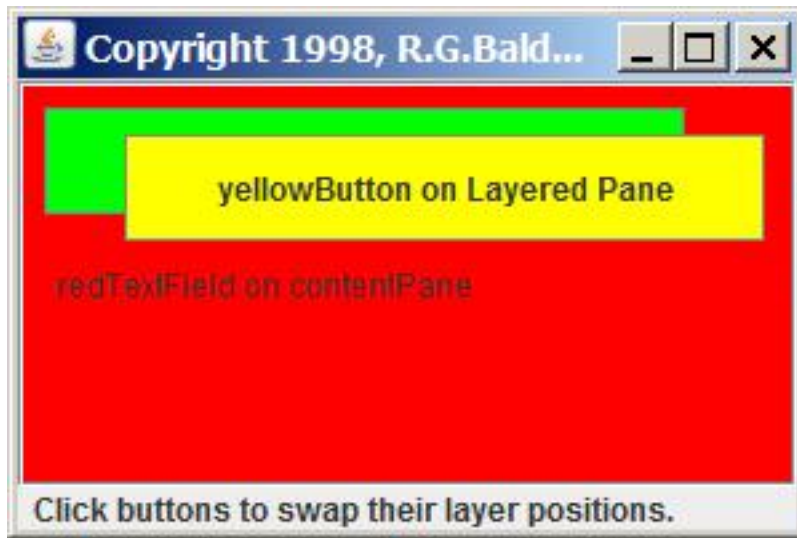

A red **JTextField** object and a **JLabel** object are placed on the *contentPane* on the **JFrame** object. The **JTextField** object is placed in the *Center* of the **JFrame** using the default border layout. The **JLabel** is placed in the *South* position on the **JFrame** object.

A green **JButton** object and a yellow **JButton** object are placed on the *layeredPane*. Apparently the default layout for the *layeredPane* is absolute or null. The **JButton** objects are purposely placed so as to partially overlap. Both buttons appear on top of the red **JTextField** object on the *contentPane*. (*Components on layered panes are always on top of components on the **contentPane***).

The green **JButton** is initially placed at layer position +1 on the layered pane and the yellow **JButton** is initially placed at layer position -29999 which is the limit in the negative direction.

Action listeners are registered on the two buttons. When the top (*green*) button is clicked, the action is to swap the layer positions of the two buttons causing the yellow button to move to the top as shown in Figure 2 (p. 1591).

Figure 2. Screen output after clicking green button.

The program was originally tested using JDK 1.1.6 and Swing 1.0.1 under Windows 95. More recently it was tested using Java 8 under Windows 7.

Several lines of code are included in the program to investigate the parent child relationships of the various panes. The text output from this part of the program, when run using Java 8, is shown in Figure 3 (p. 1592) .

Figure 3. Text output.

```
Root pane is: class javax.swing.JRootPane
Parent of root pane is SwingPane01[frame0,0,0,0x0,invalid,hidden,layout=java.awt
.BorderLayout,title=,resizable,normal,defaultCloseOperation=HIDE_ON_CLOSE,rootPa
ne=javax.swing.JRootPane[,0,0,0x0,invalid,layout=javax.swing.JRootPane$RootLayou
t,alignmentX=0.0,alignmentY=0.0,border=,flags=16777673,maximumSize=,minimumSize=
,preferredSize=],rootPaneCheckingEnabled=true]

Glass pane is: class javax.swing.JPanel
Parent of glass pane is javax.swing.JRootPane[,0,0,0x0,invalid,layout=javax.swin
g.JRootPane$RootLayout,alignmentX=0.0,alignmentY=0.0,border=,flags=16777673,maxi
mumSize=,minimumSize=,preferredSize=]

Layered pane is: class javax.swing.JLayeredPane
Parent of layered pane is javax.swing.JRootPane[,0,0,0x0,invalid,layout=javax.sw
ing.JRootPane$RootLayout,alignmentX=0.0,alignmentY=0.0,border=,flags=16777673,ma
ximumSize=,minimumSize=,preferredSize=]

Content pane is: class javax.swing.JPanel
Parent of content pane is javax.swing.JLayeredPane[null.layeredPane,0,0,0x0,inva
lid,alignmentX=0.0,alignmentY=0.0,border=,flags=0,maximumSize=,minimumSize=,pref
erredSize=,optimizedDrawingPossible=true]
```

The JavaSoft documentation indicates that the *contentPane* is placed at an equivalent layer position of -30000 in the *layeredPane* .

The `glassPane` is something of a mystery to me at this point in time (5/12/98). I was unable to draw on the `glassPane`. An attempt to place either a `JButton` object or a `JToolTip` object on the `glassPane` was rejected by the compiler with error messages that the `JButton` and the `JToolTip` could not be converted to type `JPopupMenu`. I don't know if this is proper behavior or a bug.

4.4.2.10.5.1 Interesting code fragments

I will discuss and explain this program in fragments. A complete listing of the program is provided in Listing 10 (p. 1596). Listing 1 (p. 1593) shows the import declarations required to import the Swing and AWT packages using Java 8. (*The older import declaration is shown as a comment.*)

Listing 1. Import declarations.

```
import java.awt.*;
import java.awt.event.*;
//import com.sun.java.swing.*;//JDK 1.1 version
import javax.swing.*;//JDK 1.2 version
```

The class definition for `SwingPane01` begins in Listing 2 (p. 1593).

Listing 2. Beginning of the class named `SwingPane01`.

```
class SwingPane01 extends JFrame{
    JLayeredPane theLayeredPane;
    JButton greenButton;
    JButton yellowButton;

    public static void main(String[] args){
        new SwingPane01();
    }//end main
```

As you can see in Listing 2 (p. 1593), the controlling class in this program is an object of type `JFrame` because it extends `JFrame`. This fragment also declares some instance variables that are required later in the `ActionEvent` handler to swap the two buttons between layers.

The `main` method is also included in this fragment simply to provide continuity.

Listing 3 (p. 1593) shows the beginning of the constructor where much of the work in this program is accomplished.

Listing 3. Beginning of the constructor.

```
SwingPane01(){//constructor
    //Get a ref to the layered pane for later use.
    theLayeredPane = this.getLayeredPane();
    int frameWidth = 300;
    int frameHeight = 200;
```

Listing 3 (p. 1593) begins by getting a reference to the `layeredPane` to make it more convenient to work with it later. The width and height values for the `JFrame` object are set in this fragment as well.

Listing 4 (p. 1594) shows the code that is used to discover and display the types of the different panes along with the parent-child relationships in the hierarchy of panes. This is the code that produced most of the text output shown in Figure 3 (p. 1592).

Listing 4. Get and display types of panes.

```

System.out.println("Root pane is: " +
    this.getRootPane().getClass());
System.out.println("Parent of root pane is " +
    this.getRootPane().getParent() + "\n");

System.out.println("Glass pane is: " +
    this.getGlassPane().getClass());
System.out.println("Parent of glass pane is " +
    this.getGlassPane().getParent() + "\n");

System.out.println("Layered pane is: " +
    this.getLayeredPane().getClass());
System.out.println("Parent of layered pane is " +
    this.getLayeredPane().getParent() + "\n");

System.out.println("Content pane is: " +
    this.getContentPane().getClass());
System.out.println("Parent of content pane is " +
    this.getContentPane().getParent() + "\n");

```

This code is all pretty intuitive. You should be able to surmise what it is doing simply from the names of the methods being invoked.

Listing 5 (p. 1594) instantiates a **JLabel** object and a **JTextField** object and places them on the *contentPane* .

Listing 5. Instantiate JLabel and JTextField objects.

```

JLabel theLabel = new JLabel(
    " Click buttons to swap their layer positions.");
this.getContentPane().add(theLabel,"South");

//Put a red JTextField in the Center of the JFrame on
// the content pane.
JTextField redTextField = new JTextField(
    " redTextField on contentPane");
redTextField.setBackground(Color.red);
this.getContentPane().add(redTextField,"Center");

```

The default layout manager for the *contentPane* is **BorderLayout** . This code places the red **JTextField** in the **Center** position of the *contentPane* and places the **JLabel** in the **South** position.

For the *metal* Look and Feel, the **JLabel** appears to be part of the border at the bottom of the **JFrame** object as shown in Figure 2 (p. 1591) .

The *South* **JLabel** provides instructions regarding the use of the **JButton** objects that will also be placed on the **JFrame** object.

Listing 6 (p. 1594) instantiates a green **JButton** object and places it on the *layeredPane* at layer number one (1).

Listing 6. Instantiate a green JButton object.

```

greenButton = new JButton(
    "greenButton on Layered Pane");
greenButton.setBackground(Color.green);
greenButton.setBounds(10,10,240,40);
greenButton.addActionListener(new MyActionListener());
theLayeredPane.add(greenButton,new Integer(1));

```

Note that the `setBounds` method is used to establish the location and size of the button in absolute pixel coordinates. Recall that I said earlier that apparently the default layout manager for the `layeredPane` is null. Otherwise, it would have been necessary for me to set it to null before placing this object on an absolute location and size basis.

Also note that an `ActionListener` object is registered on the `JButton` object. We will see the class that defines the behavior of the listener object later.

Listing 7 (p. 1595) instantiates a yellow `JButton` object and places it on the `layeredPane` at layer number -29999. This is the bottom-most layer of all programmable layers in the `layeredPane`. The `contentPane` falls immediately below this layer.

Listing 7. Instantiate a yellow JButton object.

```

yellowButton = new JButton(
    "yellowButton on Layered Pane");
yellowButton.setBackground(Color.yellow);
yellowButton.setBounds(40,20,240,40);
yellowButton.addActionListener(new MyActionListener());
theLayeredPane.add(yellowButton,new Integer(-29999));

```

Listing 8 (p. 1595) sets the title, size, visibility, etc., of the `JFrame` object and register an anonymous listener to terminate the program when the user closes the `JFrame`.

Listing 8. The end of the constructor.

```

this.setTitle("Copyright 1998, R.G.Baldwin");
this.setSize(frameWidth,frameHeight);
this.setVisible(true);
//=====//
//Anonymous inner class to terminate program.
this.addWindowListener(new WindowAdapter(){
    public void windowClosing(WindowEvent e){
        System.exit(0);}});//end addWindowListener

} //end constructor

```

Listing 8 (p. 1595) also signals the end of the constructor.

Listing 9 (p. 1595) shows the `ActionListener` class from which listener objects are registered on the two `JButton` objects.

Listing 9. The class named MyActionListener.

```

class MyActionListener implements ActionListener{

```

```

public void actionPerformed(ActionEvent e){
    if(e.getActionCommand().equals(
        "greenButton on Layered Pane")){
        theLayeredPane.setLayer(greenButton,-29999);
        theLayeredPane.setLayer(yellowButton,1);
    }else{
        theLayeredPane.setLayer(greenButton,1);
        theLayeredPane.setLayer(yellowButton,-29999);
    }//end else
} //end actionPerformed()
} //end class MyActionListener

```

This is a standard listener class that defines the **actionPerformed** method.

The behavior of the **actionPerformed** method in this case is to cause the layer positions of the two **JButton** objects to be swapped whenever the button on top is clicked. This causes the **JButton** object immediately below the one on the top to move to the top of the stack.

Note that this method invokes the **setLayer** method of the **JLayeredPane** class to rearrange the positions of the two **JButton** objects at runtime.

4.4.2.10.5.2 Complete program listing

Listing 10 (p. 1596) shows a complete listing of the program named **SwingPane01** .

Listing 10. Complete listing of SwingPane01.

```

/*File SwingPane01 Copyright 1998, R.G.Baldwin
Updated 7/10/16 for Java 8 compatibility.

```

```

Revised 1/12/99 for JDK 1.2 Swing compatibility

```

The purpose of this program is to illustrate the use of the content pane and the layered pane.

The program places a JFrame object on the screen as the primary GUI.

A red JTextField and a white JLabel are placed on the content pane on the JFrame object. (The white label is actually rendered as gray in the metal L&F.)

The JTextField is placed in the Center of the JFrame using the default border layout. The JLabel is placed in the South position on the JFrame object.

A green JButton and a yellow JButton are placed on the layered pane of the JFrame object. Apparently the default layout for the layered pane is absolute or null. The JButton objects are purposely placed so as to partially overlap. Both buttons appear on top of the JTextField object on the content pane.

The green JButton is initially placed at layer position +1 on the layered pane and the yellow JButton is initially placed at layer position -29999 which is the limit in the negative direction.

Action listeners are registered on the two buttons. When the top button is clicked, the action is to swap the layer positions of the two buttons causing the other one to move to the top layer position.

Several lines of code are included to investigate the parent child relationships of the various panes. The output from this part of the program follows. Note that line breaks were manually inserted here to force the material to fit in this format.

```
Root pane is: class com.sun.java.swing.JRootPane
Parent of root pane is SwingPane01
    [frame0,0,0,0x0,invalid,hidden,
    layout=java.awt.BorderLayout,resizable,title=]
```

```
Glass pane is: class com.sun.java.swing.JPanel
Parent of glass pane is com.sun.java.swing.JRootPane
    [,0,0,0x0,invalid,
    layout=com.sun.java.swing.JRootPane$RootLayout]
```

```
Layered pane is: class com.sun.java.swing.JLayeredPane
Parent of layered pane is com.sun.java.swing.JRootPane
    [,0,0,0x0,invalid,
    layout=com.sun.java.swing.JRootPane$RootLayout]
```

```
Content pane is: class com.sun.java.swing.JPanel
Parent of content pane is com.sun.java.swing.JLayeredPane
    [null.layeredPane,0,0,0x0,invalid]
```

An interpretation of the above is:

- The root pane is a child of the JFrame object.
- The glass pane is a child of the root pane.
- The layered pane is a child of the root pane.
- The content pane is a child of the layered pane.

- The root pane is of type JRootPane.
- The glass pane is of type JPanel.
- The layered pane is of type JLayeredPane.
- The content pane is of type JPanel.

The JavaSoft documentation indicates that the content pane is placed at layer position -30000 in the layered pane.

The glass pane is something of a mystery at this point.

I was unable to draw upon the glass pane. An attempt to place either a JButton object or a JToolTip object on the glass pane was rejected by the compiler with error messages that the JButton and the JToolTip could not be converted to type JPopupMenu.

Tested using JDK 1.1.6 and Swing 1.0.1 under Win95.

4.4.2.11.2 Preface

This is a page from the Event Handling ¹⁹¹ section of the book titled ITSE2317 - Java Programming (Intermediate) ¹⁹². The **Event Handling** section explains how to write programs that handle events in Java.

Students in Prof. Baldwin's **ITSE 2317 Intermediate Java Programming** classes at ACC are responsible for knowing and understanding all of the material in this lesson.

Note: An object of the **JSlider** class in Java 8 can be used for some (*but no all*) of the purposes that a **Scrollbar** object may have been used for in the early days of Java.

4.4.2.11.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

4.4.2.11.2.1.1 Figures

- Figure 1. (p. 1603) Graphic screen output for Event18.
- Figure 2. (p. 1607) Output produced by clicking right scrollbar button.
- Figure 3. (p. 1613) Graphic screen output from SampProg125.java.

4.4.2.11.2.1.2 Listings

- Listing 1. (p. 1604) The controlling class for Event18.java.
- Listing 2. (p. 1605) Beginning of the GUI class.
- Listing 3. (p. 1605) Beginning of the constructor for the GUI class.
- Listing 4. (p. 1605) Set the unit and block increments.
- Listing 5. (p. 1605) Complete the GUI.
- Listing 6. (p. 1606) Beginning of class that implements AdjustmentListener.

- Listing 9. (p. 1608) Complete listing of the program named `Event18.java`.
- Listing 10. (p. 1614) Complete listing of the program named `SampProg125.java`.

4.4.2.11.3 Introduction

JDK 1.1 was formally released on February 18, 1997. This lesson was originally written on February 21, 1997 using the software in JDK 1.1. It was upgraded to JDK 1.2 on 12/18/98. It was converted to CNXML with minor updates for publication on OpenStax on 07/11/16.

4.4.2.11.4 Overview

Event handling on a **Scrollbar** object differs from the event handling in previous lessons in several respects. The following paragraphs contrast the **Scrollbar** with the **Mouse** in order to illustrate some of the differences.

To create a listener object for the mouse, you either implement the **MouseListener** interface, or you extend the **MouseAdapter** class.

However, to create a listener object for a **Scrollbar**, you do not implement a *ScrollbarListener* interface or extend a *ScrollbarAdapter* class, because they do not exist.

Instead, you implement the **AdjustmentListener** interface. The single method declared in the **AdjustmentListener** interface receives an **AdjustmentEvent** object as a parameter. This is one of the *semantic* events (*as opposed to low-level events*) similar to **ActionEvent**, **ItemEvent**, and **TextEvent**.

As mentioned above, there is no *AdjustmentAdapter* class. It isn't needed because the **AdjustmentListener** interface declares only one method, which is shown below:

```
public abstract void adjustmentValueChanged(AdjustmentEvent e)
```

The **adjustmentValueChanged** method is invoked when the value of the adjustable object (*the Scrollbar object in this lesson*) has changed.

Recall also that there are five different types of mouse events declared in the **MouseListener** interface:

- `mouseClicked`,
- `mouseEntered`,
- `mouseExited`,
- `mousePressed`
- `mouseReleased`.

There are two additional types of mouse events that are declared in the **MouseMotionListener** interface:

- `mouseDragged`
- `mouseMoved`

Each of these different types of mouse events is represented by a method declaration in one or the other of the two interfaces defined for creating listener classes for mouse activity. You *override the method(s)* for those types of events which interest you.

There are five different types of adjustment events that correspond to the five ways of moving the bubble in a **Scrollbar** object. However, as mentioned above, there is only one method declared in the

AdjustmentListener interface. It is named **adjustmentValueChanged** . It receives an object of type **AdjustmentEvent** as a parameter when invoked.

The type of event is encoded into the object that is passed in as a parameter along with other information such as the *value* of the **Scrollbar** and the *name* of the **Scrollbar** object. The *value* of the **Scrollbar** is determined by the position of the bubble on the **Scrollbar** .

The **AdjustmentEvent** class defines several methods that can be used to extract information from the object in case you need access to that information. This is discussed in more detail later.

The types of adjustment events (*corresponding to physical methods of moving the bubble on the **Scrollbar***) are defined as static variables in the **AdjustmentEvent** class. (*This is similar to the approach used in the earlier event model in JDK 1.0.2.*) The five different types of adjustment events and their relationship to moving the bubble are:

- **UNIT_INCREMENT** - click button on one end of the Scrollbar
- **UNIT_DECREMENT** - click button on the other end of the Scrollbar
- **BLOCK_INCREMENT** - click in space between bubble and one button
- **BLOCK_DECREMENT** - click in space between bubble and other button
- **TRACK** - drag the bubble

As indicated, the two *UNIT* types are generated by clicking on the buttons at either end of the Scrollbar.

The two *BLOCK* types are generated by clicking interior to the **Scrollbar** on either side of the bubble.

The *TRACK* event is generated by dragging the bubble.

Methods are available for setting various parameters of the **Scrollbar** including the range, the width of the bubble (*alternately referred to in the documentation as page size or visible*), the size of the unit and block increments or decrements, etc.

One might surmise that this rather general purpose adjustment approach was defined to support a family of components that operate on an adjustment basis. However, a quick search of the index in the JDK 1.1.3 documentation package did not identify any other components that use the adjustment interface. Perhaps other adjustable objects are planned for future versions of the AWT. (*Note that as of Java 8, the **AdjustmentListener** interface is also implemented by the **AWTEventMulticaster** class. However, that class is not discussed in this lesson.*)

4.4.2.11.5 The sample program

This section presents a discussion of the program followed by the program listing.

4.4.2.11.5.1 Discussion

This program places a **Scrollbar** object and a **TextField** object in a **Frame** object as shown in Figure 1 (p. 1603) .

Figure 1. Graphic screen output for Event18.

Whenever the *bubble* in the **Scrollbar** is moved using any of the five available physical methods for moving the bubble, the *value* of the **Scrollbar** (*which normally should represent the position of the center of the bubble*) is extracted from the event object and displayed in the **TextField** object. (*Certain*

arithmetic corrections are required to cause the value to represent the center of the bubble because the actual value returned represents the left-hand edge of the bubble for a horizontal `Scrollbar` .)

Also, whenever the bubble is moved, several other pieces of information are extracted from the object and displayed on the command-line screen. This includes the identification of the adjustable object and the type of adjustable event.

Note also that although five different initialization parameters are included as parameters to the `Scrollbar` constructor, other important initialization parameters such as `BlockIncrement` and `UnitIncrement` are not included in the parameter list. They must be set following instantiation using methods such as `setBlockIncrement` .

Experimentation indicates that the default value for `BlockIncrement` is ten units and the default value for `UnitIncrement` is one unit.

Reiterating what was mentioned earlier, the `Scrollbar` listener object is not added as a `ScrollbarListener` but rather is defined by implementing the `AdjustmentListener` interface and then added as an `AdjustmentListener` .

The `AdjustmentListener` interface declares only one method that may be overridden: `adjustmentValueChanged` .

This method receives an object of type `AdjustmentEvent` that (as of Java 8) provides five methods that can be used to obtain information about the event.

- The `getAdjustable` method of the `AdjustmentEvent` class returns information containing the identification of the object that generated the event.
- The `getAdjustmentType` method returns information containing the identification of the type of event (click the buttons on the Scrollbar, drag the bubble, etc.).
- The `paramString` method contains a variety of information which overlaps the two above methods to some extent.
- The `getValue` method returns the value produced by the adjustment.
- The `getValueIsAdjusting` method returns true if this is one of multiple adjustment events. (*This method was not defined in the class when this lesson was originally written in 1997.*)

Three of these five methods are used in the following program. The `paramString` and `getValueIsAdjusting` methods are not used.

There are many important comments in the program that add to this discussion, particularly with respect to bugs in the `Scrollbar` component, and arithmetic adjustments required to compensate for the width of the bubble. (*Note, however, that the comments related to bugs may no longer apply in Java 8 and beyond.*)

4.4.2.11.5.2 Interesting code fragments

I will discuss and explain this program in fragments. A complete listing is provided in Listing 9 (p. 1608) .

Listing 1 (p. 1604) shows the controlling class that contains the requisite `main` method. The `main` method instantiates an object of type `GUI` where all of the work is done.

Listing 1. The controlling class for Event18.java.

```
import java.awt.*;
import java.awt.event.*;

class Event18{
    public static void main(String[] args){
        GUI gui = new GUI();
    }//end main
}//end class Event18
```

Listing 2 (p. 1605) shows the beginning of the **GUI** class along with some instance variables used later in the program.

Listing 2. Beginning of the GUI class.

```
class GUI{
    Scrollbar myScrollbar;
    TextField displayWindow;
    int bubbleWidth;//needs to be accessible by event handler
```

Listing 3 (p. 1605) shows the beginning of the constructor for the **GUI** class. The constructor begins by instantiating a **Frame** object to serve as a top-level window for the application.

Listing 3. Beginning of the constructor for the GUI class.

```
GUI(){
    Frame myFrame = new Frame("Copyright 1997, R.G.Baldwin");

    bubbleWidth = 20;
    int initialPosition = 50 - bubbleWidth/2;
    int min = 0 - bubbleWidth/2;
    int max = 100 + bubbleWidth/2;
    myScrollbar = new Scrollbar(Scrollbar.HORIZONTAL,
        initialPosition, bubbleWidth, min, max);
```

This is followed by instantiation of a horizontal **Scrollbar** object with a range from 0 to 100, an initial position at 50, a bubble width (*page size*) of 20, a unit increment of 2 (*see Listing 4 (p. 1605)*), and a block increment of 15 (*see Listing 4 (p. 1605)*).

The **Scrollbar** component does not center the bubble on the value. Rather, the left edge of the bubble is lined up with the value. The result is that values in the upper end of the range cannot be reached unless appropriate adjustments are made using half the bubble width. This distributes the unreachable values at each end of the Scrollbar. You can then set the *min* and *max* values to extend beyond the desired values by one-half the bubble width.

Listing 4 (p. 1605) sets the unit increment to 2 and the block increment to 15. The unit increment is the amount of change resulting from clicking a button on the end of the **Scrollbar**. The block increment is the amount of change resulting from clicking between the bubble and the button on the end.

Listing 4. Set the unit and block increments.

```
myScrollbar.setBlockIncrement(15);
myScrollbar.setUnitIncrement(2);
```

The code in Listing 5 (p. 1605) should be very familiar to you by now. It really isn't very interesting at this point, and is included in this section solely for completeness.

Listing 5. Complete the GUI.

```
displayWindow = new TextField("Initial Text");
displayWindow.setEditable(false);//make non-editable
```

```

//add components to the GUI
myFrame.add("South", myScrollbar);
myFrame.add("North", displayWindow);
myFrame.setSize(300,75);
myFrame.setVisible(true);

//Instantiate a listener object for the Scrollbar and
// register it to receive notification of adjustment
// events.
MyScrollbarListener myScrollbarListener =
    new MyScrollbarListener(this);
//Note that the Scrollbar listener is not added as a
// ScrollbarListener but rather is added as an
// AdjustmentListener.
myScrollbar.addAdjustmentListener(myScrollbarListener);

//Close Frame to terminate.
myFrame.addWindowListener(new MyWindowListener());
} //end constructor
} //end class GUI

```

This fragment creates the display window using a **TextField** object. It also adds the two components to the **Frame**, sets the size of the **Frame**, and makes the whole thing visible.

The fragment also includes typical code to instantiate a listener object for the **Scrollbar** and register it to receive notification of adjustment events.

This is followed by typical code to register a window listener to terminate the program when the user clicks the close box on the **Frame**.

That ends the constructor and also ends the definition of the **GUI** class.

The code in Listing 6 (p. 1606) shows the beginning of the **AdjustmentListener** class from which a listener object is instantiated and registered on the **Scrollbar** to listen for adjustment events. This fragment shows the constructor for the class that saves a reference to the **Scrollbar**.

Listing 6. Beginning of class that implements AdjustmentListener.

```

class MyScrollbarListener implements AdjustmentListener{
    GUI thisObject; //save ref to GUI object here

    MyScrollbarListener(GUI objectIn){ //constructor
        thisObject = objectIn;
    } //end constructor

```

Listing 7 (p. 1606) shows the beginning of the **adjustmentValueChanged** method, which is the only method declared by the **AdjustmentListener** interface. This method receives a parameter which is an object of type **AdjustmentEvent** and serves as the heart of this program.

Listing 7. Beginning of the adjustmentValueChanged method.

```

public void adjustmentValueChanged(AdjustmentEvent e){
    int value;

```

```
//Display the entire AdjustmentEvent object
System.out.println(e);
System.out.println("Adjustable = " + e.getAdjustable());
System.out.println("AdjustmentType = "
    + e.getAdjustmentType());
```

This fragment uses the incoming object to obtain and display

- the incoming object,
- the source of the event, and
- the type of the event.

The text output shown in Figure 2 (p. 1607) was produced by the above fragment when the button on the right end of the scrollbar was clicked with the program running under Java 8 and Windows 7.

Figure 2. Output produced by clicking right scrollbar button.

```
java.awt.event.AdjustmentEvent[ADJUSTMENT_VALUE_CHANGED,adjType=UNIT_INCREMENT,v
alue=42,isAdjusting=false] on scrollbar0
Adjustable = java.awt.Scrollbar[scrollbar0,4,51,292x20,val=42,vis=20,min=-10,max
=110,horz,isAdjusting=false]
AdjustmentType = 1
value = 42
value = 42
```

Listing 8 (p. 1607) uses the incoming object to get the *value* of the scrollbar and display it in the **TextField** object. The value should represent the position of the bubble (*it really represents the position of the left edge of the bubble, not the center*).

Listing 8. Get and display the value of the scrollbar.

```
value = e.getValue();//get and save the value

//The following code is here to work around a possible
// bug in the Scrollbar object where small negative
// values are reported as very large positive values
// when the Scrollbar is adjusted by sliding the bubble.
// Note that this bug still exists in JDK 1.1.6 but has
// been fixed in JDK 1.2.
System.out.println("value = " + value);
if(value > 65000) value = value - 65536;
System.out.println("value = " + value);
thisObject.displayWindow.setText("Value = "
    + (value + thisObject.bubbleWidth/2));

//The following seems like a kludge but is required to
// make the scrollbar bubble stay put. Otherwise, it
// jumps back to the previous value when you try to
// move it.
//Note that this statement is required for JDK 1.1.6
// but is not required for the first release of JDK 1.2
```

```

        thisObject.myScrollbar.setValue(value);
    } //end adjustmentValueChanged()

} //end class MyScrollbarListener

```

This fragment contains code to serve as a workaround for a bug in JDK 1.1.6 where small negative values are reported as very large positive values when the Scrollbar is adjusted by dragging the bubble. (*Note that this bug has been fixed in JDK 1.2.*)

The fragment also contains code to adjust the reported value to the center of the bubble instead of the left edge of the bubble by increasing the value by one-half the width of the bubble. The adjusted value is displayed in the **TextField** object.

It also contains code to resolve another bug which causes the bubble to jump back to its previous value when you attempt to drag it in JDK 1.1.6. (*This also has been fixed in JDK 1.2.*)

That concludes the interesting code fragments for this program. A complete listing is provided in the next section.

4.4.2.11.5.3 Complete program listing

Listing 9 (p. 1608) provides a complete listing of the program. As mentioned earlier, some of the comments related to bugs may no longer apply in Java 8 and beyond.

Listing 9. Complete listing of the program named Event18.java.

```

/*File Event18.java Copyright 1997, R.G.Baldwin

Revised 12/18/97
This program was designed to be compiled and executed under
JDK 1.1.3 or later version.

In an earlier version of this program compiled under
JDK 1.1, in February 1997, I reported numerous bugs in the
JDK Scrollbar handling. I have now recompiled the program
and can report that most of the bugs seem to have been fixed,
although a couple of bugs still seem to exist.

One remaining bug is that if you adjust the scrollbar by
dragging the bubble into an area which would report negative
values, large positive values are reported instead of small
negative values (ie: something like 65536 instead of -1).
This does not happen if the scrollbar is adjusted by
clicking on the end buttons or in the area between the
bubble and the buttons. A numeric workaround was
implemented in this program to work around that bug. Note
that the bug still exists in JDK 1.1.6 but was fixed in the
first release of JDK 1.2.

Another possible bug is that the scrollbar seems to be able
to report a value that is one unitIncrement too large for
the specified maximum value and bubble width. Note
that the bug still exists in JDK 1.1.6 but was fixed in the
first release of JDK 1.2.

```

This program places a Scrollbar object and a TextField object in a Frame. Whenever the bubble in the Scrollbar is moved using any of the five available methods for moving the bubble the value of the Scrollbar (which should represent the position of the bubble) is displayed in the TextField object.

Also, whenever the bubble is moved, several other pieces of information are displayed on the screen which identify various parameters of the adjustment.

Closing the frame terminates the program.

```

*/
//=====
import java.awt.*;
import java.awt.event.*;

class Event18{
    public static void main(String[] args){
        GUI gui = new GUI();
    }//end main
}//end class Event18
//=====
class GUI{
    Scrollbar myScrollbar;
    TextField displayWindow;
    int bubbleWidth;//needs to be accessible by event handler

    GUI(){
        Frame myFrame = new Frame("Copyright 1997, R.G.Baldwin");

        //Instantiate a horizontal Scrollbar object with range
        // from 0 to 100, initial position at 50, bubble width
        // (page size) of 20, unitIncrement of 2 and a
        // blockIncrement of 15.

        // The Scrollbar component does not center the bubble on
        // the value. Rather, the left edge of the bubble is
        // lined up with the value. The result is that values
        // in the upper end of the range cannot be reached
        // unless appropriate adjustments are made using half
        // the bubble width. This distributes the unreachable
        // values at each end of the Scrollbar. You can then
        // set the min and max values to extend beyond the
        // desired values by one-half the bubble width.
        bubbleWidth = 20;
        int initialPosition = 50 - bubbleWidth/2;
        int min = 0 - bubbleWidth/2;
        int max = 100 + bubbleWidth/2;
        myScrollbar = new Scrollbar(Scrollbar.HORIZONTAL,

```

```

        initialPosition, bubbleWidth, min, max);

//It would have been nice to have included unitIncrement
// and blockIncrement as parameters to the constructor
// along with the other constructor parameters. See
// next two statements which set the unitIncrement and
// the blockIncrement. The unitIncrement is the amount
// of change resulting from clicking a button on the
// end of the Scrollbar. The blockIncrement is the
// amount of change resulting from clicking between the
// bubble and the button on the end.
myScrollbar.setBlockIncrement(15);
myScrollbar.setUnitIncrement(2);

displayWindow = new TextField("Initial Text");
displayWindow.setEditable(false); //make non-editable

//add components to the GUI
myFrame.add("South", myScrollbar);
myFrame.add("North", displayWindow);
myFrame.setSize(300,75);
myFrame.setVisible(true);

//Instantiate a listener object for the Scrollbar and
// register it to receive notification of adjustment
// events.
MyScrollbarListener myScrollbarListener =
    new MyScrollbarListener(this);
//Note that the Scrollbar listener is not added as a
// ScrollbarListener but rather is added as an
// AdjustmentListener.
myScrollbar.addAdjustmentListener(myScrollbarListener);

//Close Frame to terminate.
myFrame.addWindowListener(new MyWindowListener());
} //end constructor
} //end class GUI
//=====

//Note that unlike some other components which have their
// own listener interface, this class does not implement
// ScrollbarListener because there is no such interface.
// Rather, the AdjustmentListener interface is used as a
// listener interface for Scrollbars.
class MyScrollbarListener implements AdjustmentListener{
    GUI thisObject; //save ref to GUI object here

    MyScrollbarListener(GUI objectIn){ //constructor
        thisObject = objectIn;
    } //end constructor
}

```

```

public void adjustmentValueChanged(AdjustmentEvent e){
    int value;
    //Display the entire AdjustmentEvent object
    System.out.println(e);
    System.out.println("Adjustable = " + e.getAdjustable());
    System.out.println("AdjustmentType = "
        + e.getAdjustmentType());

    //Display the value of the Scrollbar object in the
    // TextField. The value should represent the position
    // of the bubble.
    value = e.getValue();//get and save the value

    //The following code is here to work around a possible
    // bug in the Scrollbar object where small negative
    // values are reported as very large positive values
    // when the Scrollbar is adjusted by sliding the bubble.
    // Note that this bug still exists in JDK 1.1.6 but has
    // been fixed in JDK 1.2.
    System.out.println("value = " + value);
    if(value > 65000) value = value - 65536;
    System.out.println("value = " + value);
    thisObject.displayWindow.setText("Value = "
        + (value + thisObject.bubbleWidth/2));

    //The following seems like a kludge but is required to
    // make the scrollbar bubble stay put. Otherwise, it
    // jumps back to the previous value when you try to
    // move it.
    //Note that this statement is required for JDK 1.1.6
    // but is not required for the first release of JDK 1.2
    thisObject.myScrollbar.setValue(value);
} //end adjustmentValueChanged()

        System.exit(0);
    } //end windowClosing()
} //end class MyWindowListener
//=====

```

4.4.2.11.6 Review

Q - All of the **Scrollbar** bugs were eliminated in JDK 1.1.3: True or False? If false, explain why.

A - False. JDK 1.1.3 appears to still have at least two Scrollbar bugs. One bug causes the *track* event (which involves dragging the bubble in the Scrollbar object) to return large positive values such as 65535 when it should be returning small negative values such as -1. The other apparent bug allows the different

versions of the event to return a value larger than would be calculated using the minimum and maximum values along with the width of the bubble.

Q - The **Scrollbar** bugs listed above cause the **Scrollbar** component to be completely unusable: True or False? If false, explain why.

A - False. While these two bugs represent a significant inconvenience, it is probably possible to work around both of them by making numeric corrections.

Q - To create a listener object for a **Scrollbar**, you must implement the *ScrollbarListener* interface or extend a *ScrollbarAdapter* class: True or False? If false, explain why.

A - False. To create a listener object for a **Scrollbar**, you do not implement a *ScrollbarListener* interface or extend a *ScrollbarAdapter* class, because they do not exist. Instead, you implement an **AdjustmentListener** interface.

Q - To create a listener object for a **Scrollbar**, you can either implement the *AdjustmentListener* interface or extend the *AdjustmentAdapter* class: True or False? If False, explain why.

A - False. There is no *AdjustmentAdapter* class. It isn't needed because the **AdjustmentListener** interface declares only one method with the following signature:

```
public abstract void adjustmentValueChanged(AdjustmentEvent e)
```

Q - The **adjustmentValueChanged** method is invoked when the value of the **Scrollbar** object is changed: True or False? If false, explain why.

A - True.

Q - There are five different types of adjustment events that correspond to the different methods of moving the bubble in a **Scrollbar** object: True or False. If false, explain why.

A - True.

Q - As with most of the other classes in the AWT, the *AdjustmentListener* interface declares a separate method for each type of adjustment event. Each of these methods must be implemented in any class that implements the *AdjustmentListener* interface: True or False? If false, explain why.

A - False. Only one method is declared in the *AdjustmentListener* interface. The name of the method is **adjustmentValueChanged**.

Q - The **adjustmentValueChanged** method receives an object of type **AdjustmentEvent** as a parameter, and the type of event is encoded into the object: True or False? If false, explain why.

A - True.

Q - In addition to the type of the event, additional information is also encoded into the object that is passed to the **adjustmentValueChanged** method. Give examples of two other kinds of information encoded into the object..

A - Information such as the *value* of the **Scrollbar** and the *name* of the **Scrollbar** component is also encoded into the object.

Q - The types of adjustment events are defined as static variables in the **AdjustmentEvent** class. What are the names of these variables, and how do they correspond to user actions on the **Scrollbar** object?

A - The names of the **static** variables and their relationship to the **Scrollbar** object are:

- **UNIT_INCREMENT** - click button on one end of the Scrollbar
- **UNIT_DECREMENT** - click button on the other end of the Scrollbar
- **BLOCK_INCREMENT** - click in space between bubble and one button
- **BLOCK_DECREMENT** - click in space between bubble and other button
- **TRACK** - drag the bubble

Q - The width of the bubble is also referred to by at least two other terms in the **Scrollbar** documentation. What are they?

A - The other terms used to describe the bubble width are *page size* and *visible* . These terms seem to be related to the use of a **Scrollbar** on the side or bottom of a window of text where the size of the bubble is indicative of the amount of text that is visible in the window in relation to the amount of text in the entire document..

Q - In JDK 1.1.3, the *value* of the **Scrollbar** object is represented by the center of the bubble: True or False? If false, explain why.

A - False. The *value* of the **Scrollbar** object is represented by an edge of the bubble. For example, the *value* is represented by the position of the left edge of the bubble for a horizontal **Scrollbar** . If you want the position of the center of the bubble to represent a *value* , you must perform a numeric correction (*involving half the width of the bubble*) on the *value* of the **Scrollbar** actually extracted from the event object.

Q - All necessary initialization parameters for a **Scrollbar** object are provided as parameters to one of the **Scrollbar** constructors: True or False: If false, explain why.

A - False. Although five different initialization parameters are included as parameters to the **Scrollbar** constructor, other important initialization parameters such as **BlockIncrement** and **UnitIncrement** are not included in the parameter list. They must be set following instantiation using methods such as **setBlockIncrement** .

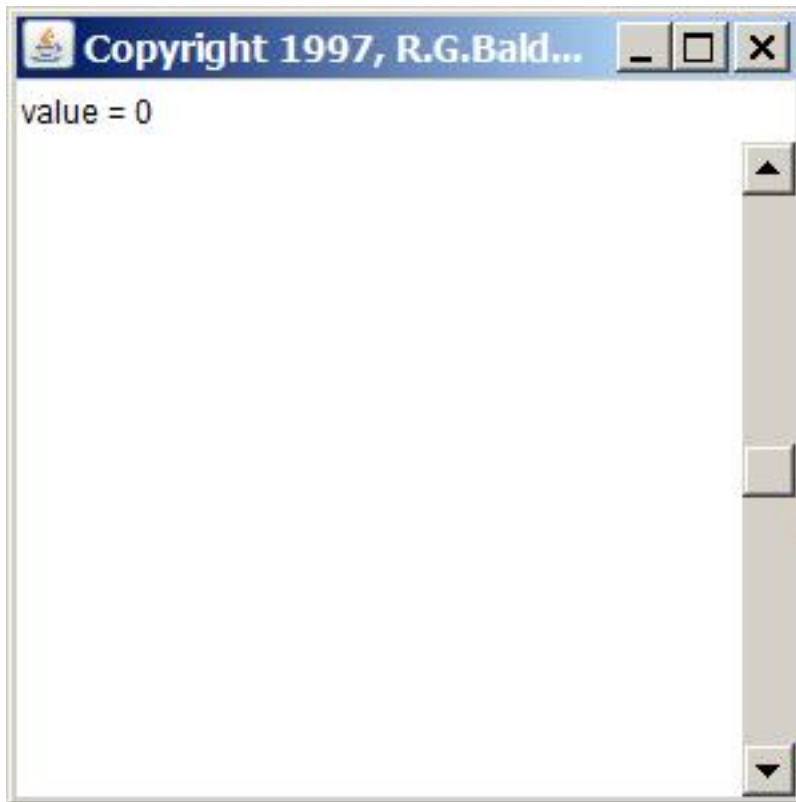

Q - The **AdjustmentEvent** class provides five methods that can be used to obtain information about the event. What are they and what kinds of information do they return?

A - The five methods and the information that they return are listed below:

- The **getAdjustable** method returns the identification of the object that generated the event.
- The **getAdjustmentType** method returns the identification of the type of event.
- The **paramString** method returns a variety of information which overlaps the two above methods to some extent.
- The **getValue** method returns the *value* produced by the adjustment.
- The **getValueIsAdjusting** method returns true if this is one of multiple adjustment events. (*This method was not defined in the class when this lesson was originally written in 1997.*)

Q - Write an application that meets the specifications given in the comments in the program shown in Listing 10 (p. 1614) . The graphic screen output produced by the program is shown in Figure 3 (p. 1613) .

Figure 3. Graphic screen output from SampProg125.java.

Listing 10. Complete listing of the program named SampProg125.java.

```
/*File SampProg125.java from lesson 90
Copyright 1997, R. G. Baldwin
Without viewing the following solution, write a Java
application that meets the specifications given below.
```

To accommodate this program, you will need to be using
JDK 1.1.3 or a later version.

Write an application that places a vertical Scrollbar and a
Label on a Frame. The Label is used to display the
position of the center of the bubble in the Scrollbar.

The Scrollbar values should range from approximately -50
to +50 (exact end points are difficult to achieve).

The width of the bubble should be 10 units.

When you click on the buttons at the end of the Scrollbar,
the bubble should move by 3 units.

When you click in the area between the bubble and the

buttons, the bubble should move by 6 units.

When the program starts, the bubble should be centered and the Label should indicate a bubble position of 0.

Closing the frame terminates the program.

End of specifications.

```

*/
//=====
import java.awt.*;
import java.awt.event.*;

class SampProg125{
    public static void main(String[] args){
        GUI gui = new GUI();
    }//end main
}//end class SampProg125
//=====
class GUI{
    Scrollbar myScrollbar;
    Label displayWindow;
    int bubbleWidth;//needs to be accessible by event handler

    GUI(){
        Frame myFrame = new Frame("Copyright 1997, R.G.Baldwin");

        bubbleWidth = 10;
        int initialPosition = 0 - bubbleWidth/2;
        int min = -50 - bubbleWidth/2;
        int max = 50 + bubbleWidth/2;
        myScrollbar = new Scrollbar(Scrollbar.VERTICAL,
            initialPosition, bubbleWidth, min, max);

        myScrollbar.setBlockIncrement(6);
        myScrollbar.setUnitIncrement(3);

        displayWindow = new Label("value = 0");

        //add components to the GUI
        myFrame.add("East", myScrollbar);
        myFrame.add("North", displayWindow);
        myFrame.setSize(300,300);
        myFrame.setVisible(true);

        //Instantiate a listener object for the Scrollbar and
        // register it to receive notification of adjustment
        // events.
        MyScrollbarListener myScrollbarListener =
            new MyScrollbarListener(this);
        //Note that the Scrollbar listener is not added as a

```

```

// ScrollbarListener but rather is added as an
// AdjustmentListener.
myScrollbar.addAdjustmentListener(myScrollbarListener);

//Close Frame to terminate.
myFrame.addWindowListener(new MyWindowListener());
} //end constructor
} //end class GUI
//=====

//Note that unlike some other components which have their
// own listener interface, this class does not implement
// ScrollbarListener because there is no such interface.
// Rather, the AdjustmentListener interface is used as a
// listener interface for Scrollbars.
class MyScrollbarListener implements AdjustmentListener{
    GUI thisObject; //save ref to GUI object here

    MyScrollbarListener(GUI objectIn){ //constructor
        thisObject = objectIn;
    } //end constructor

    public void adjustmentValueChanged(AdjustmentEvent e){
        int value;

        //Display the value of the Scrollbar object in the
        // Label. The value should represent the position
        // of the bubble.
        value = e.getValue(); //get and save the value

        //The following code is here to work around a possible
        // bug in the Scrollbar object where small negative
        // values are reported as very large positive values
        // when the Scrollbar is adjusted by sliding the bubble.
        if(value > 65000) value = value - 65536;
        thisObject.displayWindow.setText("Value = "
            + (value + thisObject.bubbleWidth/2));

        //The following seems like a kludge but is required to
        // make the scrollbar bubble stay put. Otherwise, it
        // jumps back to the previous value when you try to
        // move it.
        thisObject.myScrollbar.setValue(value);
    } //end adjustmentValueChanged()

} //end class MyScrollbarListener
//=====
//Listener to terminate the program when the Frame is
// closed.
class MyWindowListener extends WindowAdapter{
    public void windowClosing(WindowEvent e){

```

```

        System.exit(0);
    } //end windowClosing()
} //end class MyWindowListener

4.4.2.18.2 Preface

Over the years, I have published a large number of tutorials in the areas of computer programming and digital signal processing (DSP). As I have time available, I am converting the more significant of those tutorials into cnxml code and re-publishing them at cnx.org²⁵⁴.

In the meantime, this is one of the pages in a book titled Object-Oriented Programming (OOP) with Java²⁵⁵ that presents PDF versions of the original tutorials to make them readily available for Connexions users. When I have time available, I plan to update this tutorial and to re-publish it as a standard page at cnx.org²⁵⁶.

This tutorial may contain internal links to other tutorials that I have written and published somewhere on the web. Those links may, or may not still be good. In any event, if you search cnx.org²⁵⁷ for the tutorial by title or by topic, you will probably find a clean copy of the referenced tutorial at cnx.org²⁵⁸. If not, you can probably use a Google Advanced Search²⁵⁹ to find a copy somewhere on the web.

4.4.2.18.3 Tutorial and code links

- Tutorial and code links (p. 1636)
- Miscellaneous (p. 1636)

4.4.2.27.2 Preface

Over the years, I have published a large number of tutorials in the areas of computer programming and digital signal processing (DSP). As I have time available, I am converting the more significant of those tutorials into cnxml code and re-publishing them at cnx.org³⁴⁴ .

In the meantime, this is one of the pages in a book titled Object-Oriented Programming (OOP) with Java³⁴⁵ that presents PDF versions of the original tutorials to make them readily available for Connexions users. When I have time available, I plan to update this tutorial and to re-publish it as a standard page at cnx.org³⁴⁶ .

This tutorial may contain internal links to other tutorials that I have written and published somewhere on the web. Those links may, or may not still be good. In any event, if you search cnx.org³⁴⁷ for the tutorial by title or by topic, you will probably find a clean copy of the referenced tutorial at cnx.org³⁴⁸ . If not, you can probably use a Google Advanced Search³⁴⁹ to find a copy somewhere on the web.

4.4.3.1.1.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

The program described in this module requires the use of the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library³⁹⁴ .

³⁹²<http://cnx.org/>

³⁹³This content is available online at <<http://cnx.org/content/m44330/1.5/>>.

³⁹⁴<http://cnx.org/content/m44148/latest/>

4.4.3.1.1.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

4.4.3.1.1.2.1.1 Figures

- Figure 1 (p. 1642) . The required graphic output image.
- Figure 2 (p. 1643) . Required output on the command line screen.

4.4.3.1.1.2.1.2 Listings

- Listing 1 (p. 1644) . Modification to load a jpg file by default.
- Listing 2 (p. 1645) . Original array containing turtle colors.
- Listing 3 (p. 1645) . Modified array of turtle colors.
- Listing 4 (p. 1646) . Change the initial heading.
- Listing 5 (p. 1647) . Source code for driver class named Prob01..
- Listing 6 (p. 1647) . Source code for the modified World class..
- Listing 7 (p. 1653) . Source code for the modified SimpleTurtle class..

4.4.3.1.1.3 Preview

Program specifications

Write a program named **Prob01** that uses the class definition shown in Listing 5 (p. 1647) and Ericson's media library along with the image file named **Prob01.jpg** to produce the graphic output image shown in Figure 1 (p. 1642) .

Figure 1 - The required graphic output image.

No new classes

You may **not** define any new classes to cause your program to behave as required, and you may not modify the class definition for the class named **Prob01** given in Listing 5 (p. 1647) . You must copy and modify (if necessary) the following media classes to cause your program to produce the required output:

- World.java
- Turtle.java
- SimpleTurtle.java

Files in your folder

Your folder must contain only the following class files, source-code files, and image files:

- Prob01.class
- Prob01.java
- Prob01.jpg
- SimpleTurtle.class
- SimpleTurtle.java
- Turtle.class
- Turtle.java
- World.class
- World.java

Output text

In addition to the output image described above, your program must produce the output text on the command- line screen shown in Figure 2 (p. 1643) .

Figure 2 - Required output on the command line screen.

```
Dick Baldwin
Picture, filename Prob01.jpg height 274 width 365
Dick Baldwin
Dick Baldwin
Dick Baldwin
Dick Baldwin
```

Table 4.230

You must substitute your name for mine wherever my name appears in the image and on the command-line screen.

An analysis

As is often the case, the real challenge with this problem is to decide what needs to be done to satisfy the specifications.

Required modifications

By comparing the default behavior of the **World** and **SimpleTurtle** classes with the requirements of this program, it can be determined that the following modifications to the **World** and **SimpleTurtle** classes are required to meet the specifications. (*Modification of the **Turtle** class is not required*) :

- Modify the **World** class to load a picture named **Prob01.jpg** as the default background for the world in place of the all-white **Picture** object.
- Modify the **World** class to display the student's name near the top of the image.

- Modify the **World** class to display the student's name and information about the picture on the command-line screen.
- Modify the **SimpleTurtle** class to change the initial heading for new turtle objects to northeast instead of north.
- Modify the **SimpleTurtle** class to change the order in which colors are assigned to new turtles as they are instantiated.

4.4.3.1.1.4 Discussion and sample code

4.4.3.1.1.4.1 Modifications to the World class

Ericson's **World** class was modified to cause it to load a jpg file by default instead of displaying a blank picture by default. It was also modified to cause it to display text on the background image and to display text on the command line screen. These changes are reflected in Figure 1 (p. 1642) and Figure 2 (p. 1643) .

A complete listing of the modified **World** class is shown in Listing 6 (p. 1647) .

Modifying the code

The code used to accomplish the modifications described above is shown in Listing 1 (p. 1644) .

Listing 1 - Modification to load a jpg file by default.

```
//create the background picture

//picture = new Picture(width,height);

picture = new Picture("Prob01.jpg");
picture.addMessage("Dick Baldwin",10,20);
System.out.println(picture);
```

Table 4.231

Note that one original statement was disabled and replaced by three new statements.

In addition, several other **println** statements were added at strategic locations within the **World** and **SimpleTurtle** classes (*not shown here*) to cause the student's name to appear multiple times in the text output shown in Figure 2 (p. 1643) .

Meeting the requirements

These modifications to the **World** and **SimpleTurtle** classes met the following requirements established earlier under Analysis ³⁹⁵ .

- Modify the **World** class to load a picture named **Prob01.jpg** as the default background for the world in place of the all-white **Picture** object.
- Modify the **World** class to display the student's name near the top of the image.
- Modify the **World** class to display the student's name and information about the picture on the command-line screen.

³⁹⁵<http://cnx.org/content/m44330/latest/Lecture01.htm#Analysis>

4.4.3.1.1.4.2 Modifications to the SimpleTurtle class

The **SimpleTurtle** class was modified to change the order in which colors are assigned to new turtle objects and to change the initial heading of the turtle from north to northeast.

A complete listing of the modified **SimpleTurtle** class is shown in Listing 7 (p. 1653) near the end of the module.

Change the order of color assignment

Listing 2 (p. 1645) declares and initializes an array of color data that is used in the original version of the **SimpleTurtle** class to assign colors to the turtles on a cyclical basis as they are instantiated.

Listing 2 - Original array containing turtle colors.

```

    /** array of colors to use for the turtles */
    private static Color[] colorArray =
    { Color.green,
      Color.cyan,
      new Color(204,0,204),
      Color.gray};

```

Table 4.232

Listing 3 (p. 1645) declares and initializes a modified version of the array of color data that is used to assign colors to the turtles as they are instantiated.

Listing 3 - Modified array of turtle colors.

```

    /** array of colors to use for the turtles */
    private static Color[] colorArray =
    { Color.cyan,
      new Color(204,0,204),
      Color.green,
      Color.gray};

```

Table 4.233

Determining which color to use

The code that assigns colors to the turtles as they are instantiated keeps track of the number of turtle objects that have been instantiated.

An index is computed as the

turtle count modulus the length of the array .

The colors are extracted from the array on a cyclical basis as more and more turtle objects are instantiated.

Each time the number of turtles is evenly divisible by the length of the array, the index used to access colors from the array starts over at zero.

Meeting the requirements

This modification to the **SimpleTurtle** class accomplished the following requirement established earlier under Analysis ³⁹⁶ .

³⁹⁶<http://cnx.org/content/m44330/latest/Lecture01.htm#Analysis>

- Modify the **SimpleTurtle** class to change the order in which colors are assigned to new turtles as they are instantiated.

Change the initial heading

Listing 4 (p. 1646) modifies the initialization value for a variable named **heading**, which is used to establish the direction that the turtle is facing.

Listing 4 - Change the initial heading.

```

    /** heading angle */
    //THIS IS A MODIFICATION
    //private double heading = 0;//default faces north
    private double heading = 45;// default faces northeast

```

Table 4.234

The default direction in the original version of the class is due north or zero degrees. The modified default direction is northeast or 45 degrees.

Meeting the requirements

This modification to the **SimpleTurtle** class accomplished the following requirement established earlier under Analysis ³⁹⁷.

- Modify the **SimpleTurtle** class to change the initial heading for new turtle objects to northeast instead of north.

That completes the required modifications that were established under Analysis ³⁹⁸.

4.4.3.1.1.5 Run the program

I encourage you to copy the code from Listing 5 (p. 1647), Listing 6 (p. 1647), and Listing 7 (p. 1653). Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

Click Prob01.jpg ³⁹⁹ to download the required input image file.

4.4.3.1.1.6 Summary

You learned how to make simple modification to the **World** and **SimpleTurtle** classes that modify how a program that uses Ericson's library behaves.

4.4.3.1.1.7 What's next?

This module dealt with modifications to the **World** and **SimpleTurtle** Classes. The next module will deal with modifications to the **Turtle** and **SimpleTurtle** Classes.

4.4.3.1.1.8 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java OOP: Modifying the World and SimpleTurtle Classes
- File: Java3102.htm
- Revised: 02/06/16

Disclaimers: Financial : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

In the past, unknown individuals have copied my modules from cnx.org, converted them to Kindle books, and placed them for sale on Amazon.com showing me as the author. I neither receive compensation for those sales nor do I know who does receive compensation. If you purchase such a book, please be aware that it is a copy of a module that is freely available on cnx.org and that it was made and published without my prior knowledge.

Affiliation : I am a professor of Computer Information Technology at Austin Community College in Austin, TX.

4.4.3.1.1.9 Complete program listings

Complete listings of the classes discussed in this module are shown in Listing 5 (p. 1647) , Listing 6 (p. 1647) , and Listing 7 (p. 1653) below.

Listing 5 - Source code for driver class named Prob01.

```
public class Prob01{
public static void main(String[] args){
    World mars = new World(200,250);
    Turtle joe = new Turtle(mars);
    joe.forward();
    Turtle bill = new Turtle(mars);

4.4.3.1.2.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

The program described in this module requires the use of the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library⁴⁰¹.

4.4.3.1.2.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

⁴⁰⁰This content is available online at <<http://cnx.org/content/m44348/1.5/>>.

⁴⁰¹<http://cnx.org/content/m44148/latest/>

4.4.3.1.2.2.1.1 Figures

- Figure 1 (p. 1668) . Required screen output.
- Figure 2 (p. 1669) . Required text output.

4.4.3.1.2.2.1.2 Listings

- Listing 1 (p. 1670) . Modified Turtle constructor. .
- Listing 2 (p. 1670) . Modified SimpleTurtle constructor.
- Listing 3 (p. 1671) . Modified toString method.
- Listing 4 (p. 1672) . Source code for the class named Prob02.
- Listing 5 (p. 1672) . Modified Turtle class.
- Listing 6 (p. 1674) . Modified SimpleTurtle class.

4.4.3.1.2.3 Preview

Program specifications

Write a program named **Prob02** that uses the class definition shown in Listing 4 (p. 1672) and Ericson's media library to produce the graphic output image shown in Figure 1 (p. 1668) .

Figure 1 - Required screen output.

No new classes allowed

You may not define any new classes to cause your program to behave as required, and you may not modify the class definition for the class named **Prob02** given in Listing 4 (p. 1672) .

Files in your folder

You must copy and modify (as necessary) the media classes named **Turtle.java** and **SimpleTurtle.java** from Ericson's library to cause your program to produce the required output.

Your folder must contain only the following class files and source-code files:

- Prob02.class
- Prob02.java
- SimpleTurtle.class
- SimpleTurtle.java
- Turtle.class
- Turtle.java

Output text

In addition to the output image described above, your program must produce the text output shown in Figure 2 (p. 1669) on the command-line screen

Figure 2 - Required text output.
Dick Baldwin My name is Joe the turtle.

Table 4.236

Required modifications

By comparing the default behavior of the **Turtle** and **SimpleTurtle** classes with the requirements of this program, it can be determined that the following modifications to the **Turtle** and **SimpleTurtle** classes are required to meet the specifications.

1. Modify the **Turtle** class to cause the student's name to be displayed on the command line.
2. Modify the **Turtle** and **SimpleTurtle** classes to accept and save a **String** parameter in addition to the **World** parameter when the Turtle object is constructed.
3. Modify the **SimpleTurtle** class to cause the default background of the world to be BLUE.
4. Modify the **SimpleTurtle** class to cause the student's name to be displayed near the top of the **World** image.
5. Modify the **toString** method in the **SimpleTurtle** class to cause it to return the value of the **String** parameter whenever the **toString** method is called. This causes the **drawInfoString** method to display the string in place of its normal behavior. It also causes the last statement in Listing 4 (p. 1672) to display the turtle's name.

4.4.3.1.2.4 Discussion and sample code**4.4.3.1.2.4.1 Modifications to the Turtle class**

Ericson's **Turtle** class was modified according to the first two items listed above under required modifications ⁴⁰².

A complete listing of the modified **Turtle** class is provided in Listing 5 (p. 1672) near the end of the module.

Modification to the Turtle constructor

⁴⁰²http://cnx.org/content/m44348/latest/Lecture02.htm#Required_modifications

The **Turtle** class has several overloaded constructors. One of the constructors was modified to accept a **String** parameter in addition to the **World** parameter and pass the new parameter along to the superclass constructor. The code is shown in Listing 1 (p. 1670) .

Listing 1 - Modified Turtle constructor.

```
public Turtle (ModelDisplay modelDisplay,
              String turtleName){
    // let the parent constructor handle it
    super(modelDisplay,turtleName);
    System.out.println("Dick Baldwin");
}
```

Table 4.237

A **println** statement was also added to the modified constructor to cause it to display the student's name on the command line screen when the **Turtle** object is constructed as shown in Figure 2.

4.4.3.1.2.4.2 Modifications to the SimpleTurtle class

A complete listing of the modified **SimpleTurtle** class is shown in Listing 6 (p. 1674) near the end of the module.

The superclass of the Turtle class

The **SimpleTurtle** class is the superclass of the **Turtle** class. Therefore, the **SimpleTurtle** class must be modified to accept the **String** parameter passed to the superclass in Listing 1 (p. 1670) . This was accomplished by modifying one of the constructors of the **SimpleTurtle** class as shown in Listing 2 (p. 1670) .

Listing 2 - Modified SimpleTurtle constructor.

```
String turtleName = null;

public SimpleTurtle(ModelDisplay display,
                  String turtleName){

    // call constructor that takes x and y
    this((int) (display.getWidth() / 2),
         (int) (display.getHeight() / 2));
    modelDisplay = display;
    display.addModel(this);

    //THIS IS THE MODIFICATION
    this.turtleName = turtleName;
    Picture picture = ((World)(display)).getPicture();
    picture.setAllPixelsToAColor(Color.BLUE);
    picture.addMessage("Dick Baldwin",10,20);
}
```

Table 4.238

The modification is shown in the last four statements in Listing 2 (p. 1670) . This modification satisfies items 2, 3, and 4 listed earlier under required modifications ⁴⁰³ .

Modified toString method

Listing 3 (p. 1671) shows the modified `toString` method that satisfies item 5 listed above under required modifications ⁴⁰⁴ .

Listing 3 - Modified toString method.

```
public String toString(){
//return this.name + " turtle at " + this.xPos + ", " +
//    this.yPos + " heading " + this.heading + ".";
return "My name is " + turtleName + " the turtle.";
} //end toString
```

Table 4.239

The original code was preserved as comments in Listing 3 (p. 1671) , and the new modified code is shown below those comments.

4.4.3.1.2.5 Run the program

I encourage you to copy the code from Listing 4 (p. 1672) , Listing 5 (p. 1672) , and Listing 6 (p. 1674) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.3.1.2.6 Summary

You learned how to:

1. Modify the `Turtle` class to cause the student's name to be displayed on the command line.
2. Modify the `Turtle` and `SimpleTurtle` classes to accept and save a `String` parameter in addition to the `World` parameter when the `Turtle` object is constructed.
3. Modify the `SimpleTurtle` class to cause the default background of the world to be BLUE.
4. Modify the `SimpleTurtle` class to cause the student's name to be displayed near the top of the `World` image.
5. Modify the `toString` method in the `SimpleTurtle` class to cause it to return the value of the `String` parameter whenever the `toString` method is called. This causes the `drawInfoString` method to display the string in place of its normal behavior. It also causes the last statement in Listing 4 (p. 1672) to display the turtle's name.

4.4.3.1.2.7 What's next?

In the next module, you will learn how to incorporate GUI components into a `World` object. In particular, you will learn how to add a `JButton` object to a `World` object and register an action listener on the button to control the behavior of the program.

⁴⁰³http://cnx.org/content/m44348/latest/Lecture02.htm#Required_modifications

⁴⁰⁴http://cnx.org/content/m44348/latest/Lecture02.htm#Required_modifications

4.4.3.1.2.8 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java OOP: Modifications to the Turtle and SimpleTurtle Classes
- File: Java3104.htm
- Revised: 02/06/16

Disclaimers: Financial : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

In the past, unknown individuals have copied my modules from cnx.org, converted them to Kindle books, and placed them for sale on Amazon.com showing me as the author. I neither receive compensation for those sales nor do I know who does receive compensation. If you purchase such a book, please be aware that it is a copy of a module that is freely available on cnx.org and that it was made and published without my prior knowledge.

Affiliation : I am a professor of Computer Information Technology at Austin Community College in Austin, TX.

4.4.3.1.2.9 Complete program listing

Complete listings of the programs discussed in this module are shown below.

Listing 4 - Source code for the class named Prob02.
<pre>import java.awt.Color; public class Prob02{ public static void main(String[] args){ World mars = new World(200,300); Turtle joe = new Turtle(mars,"Joe"); joe.moveTo(20,280); joe.setInfoColor(Color.WHITE); joe.setShowInfo(true); System.out.println(joe); }//end main method }//end class Prob02</pre>

Table 4.240

Listing 5 - Modified Turtle class.

/*12/23/0812/23/08 This class and the class named SimpleTurtle were modified to:

Accept and save a String parameter in addition to the World parameter when the Turtle object is constructed.

Modify the toString method to cause it to return the value of the String parameter whenever the toString method is called. This causes the drawInfoString method to display the string in place of its normal behavior.

Cause the default background of the world to be BLUE.

Cause the student's name to be displayed near the top of the World image.

Cause the student's name as well as the turtle's name to be displayed on the command line.

- Miscellaneous (p. 1698)
- Complete program listing (p. 1698)

4.4.3.1.3.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

The program described in this module requires the use of the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library⁴⁰⁶.

4.4.3.1.3.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

4.4.3.1.3.2.1.1 Figures

- Figure 1 (p. 1690) . Initial screen output.
- Figure 2 (p. 1690) . Screen output after clicking the button.
- Figure 3 (p. 1692) . Required text output.

4.4.3.1.3.2.1.2 Listings

- Listing 1 (p. 1692) . The new `getFrame` method.
- Listing 2 (p. 1693) . `Prob03` class definition.
- Listing 3 (p. 1693) . Beginning of the `Prob03Runner` class.
- Listing 4 (p. 1694) . Beginning of the `run` method.
- Listing 5 (p. 1695) . Register an action listener on the button.
- Listing 6 (p. 1695) . Set the picture background to blue.
- Listing 7 (p. 1697) . Display the student's name on the picture.
- Listing 8 (p. 1697) . Add a turtle to the world.
- Listing 9 (p. 1698) . Source code for the program named `Prob03`.
- Listing 10 (p. 1699) . The modified `World` class.

⁴⁰⁶<http://cnx.org/content/m44148/latest/>

4.4.3.1.3.3 Preview

In this module, you will learn how to incorporate GUI components into a **World** object. In particular, you will learn how to add a **JButton** object to a **World** object and register an action listener on the button to control the behavior of the program.

Program specifications

Write a program named **Prob03** that uses the **Prob03** class definition shown in Listing 2 (p. 1693) and Ericson's media library to produce the graphic output images shown in Figure 1 (p. 1690) and Figure 2 (p. 1690).

The image shown in Figure 1 (p. 1690) is the image that appears on the screen when the program starts running.

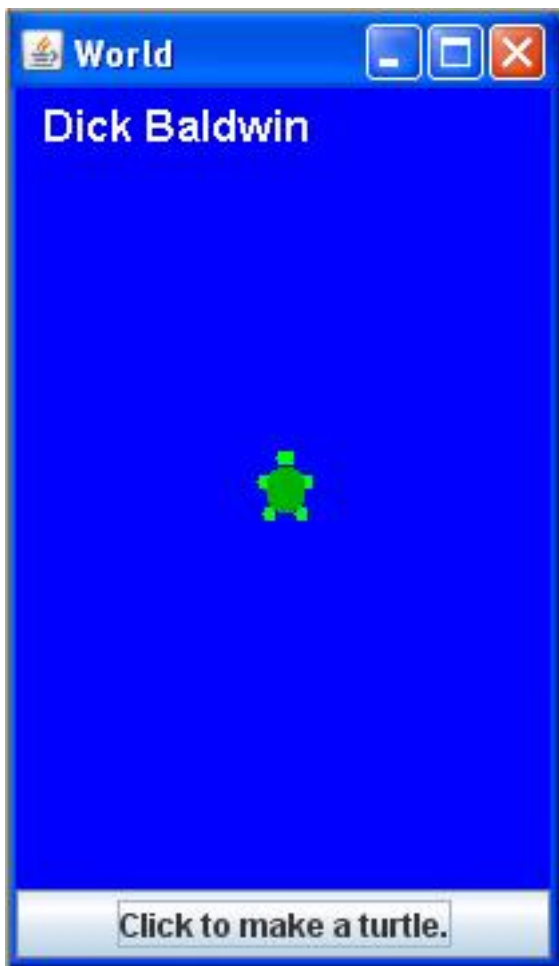

Figure 1 - Initial screen output.

Click the button

The image shown in Figure 2 (p. 1690) is what you should see when you click the button at the bottom of the world.

Figure 2 - Screen output after clicking the button.

Modify Ericson's `World` class

You must copy and modify (as necessary) the media class named `World` to cause your program to produce the required output with the required behavior.

Add a `JButton` to the `World`

This program adds a `JButton` object to the SOUTH location of the `World` object as shown in Figure 1 (p. 1690) and Figure 2 (p. 1690) and registers an action listener on the button to control the behavior of the program.

Program behavior

The program initially displays an empty white world as shown in Figure 1 (p. 1690) . When the user clicks the button, the world's background color changes to blue, a turtle appears in the center of the `World` , and the student's name appears near the top of the world.

Output text

In addition to the output images described above, your program must produce the text output shown in Figure 3 (p. 1692) on the command- line screen

Figure 3 - Required text output.

```

    Dick Baldwin
Dick Baldwin
Picture, filename None height 300 width 200

```

Table 4.241**Analysis**

A **World** object is actually a specialized use of a standard Java **JFrame** object. However, by default, the frame is not available to users of the **World** class. Therefore, in order to satisfy the requirements of this program, the **World** class must be modified to provide access to the frame.

Add a getFrame method

This program adds a method named **getFrame** to the **World** class. The **getFrame** method returns a reference to the **JFrame** object that is used to display the world. This makes it possible to treat **World** objects in much the same way that other **JFrame** objects are treated.

Add a button and pack the frame

The program uses the **JFrame** object's reference to add a **JButton** object to the SOUTH location of the **JFrame** . After adding the button, the program calls the **pack** method on the frame to cause the size of the frame to be automatically adjusted to accommodate both the **Picture** object that constitutes the background and the **JButton** object.

4.4.3.1.3.4 Discussion and sample code**4.4.3.1.3.4.1 Modification to the World class**

A complete listing of the modified **World** class is provided in Listing 10 (p. 1699) near the end of the module

Getting access to the frame

An object of the **World** class contains a private instance variable named **frame** that contains a reference to the **JFrame** object. Because it is private, however, it is not available to users of the **World** class. The *getter* method shown in Listing 1 (p. 1692) was added to the **World** class to provide access to the **JFrame** .

Listing 1 - The new getFrame method.

```

    public JFrame getFrame(){
    System.out.println("Dick Baldwin");
    return frame;
    }//end getFrame

```

Table 4.242

The new method also displays the student's name when the method is called, producing part of the text output in Figure 3 (p. 1692) .

No other change to is required

This is the only change to Ericson's library that is required to write this program. Everything else in the program makes use of existing library classes with no modifications.

4.4.3.1.3.4.2 The Prob03Runner class

Will explain in fragments

I will explain this program in fragments. A complete listing is shown in Listing 9 (p. 1698) near the end of the module.

The driver class

The driver class for this program is named **Prob03** . The definition of the driver class is shown in its entirety in Listing 2 (p. 1693) .

Listing 2 - Prob03 class definition.

```
import java.awt.BorderLayout;
import javax.swing.JFrame;
import javax.swing.JButton;
import java.awt.event.ActionListener;
import java.awt.event.ActionEvent;
import java.awt.Color;

public class Prob03{
    public static void main(String[] args){
        new Prob03Runner().run();
    }//end main method
}//end class Prob03
```

Table 4.243

The driver class simply instantiates a new object of a class named **Prob03Runner** and calls a method named **run** on that object.

Beginning of the Prob03Runner class

The beginning of the **Prob03Runner** class and the constructor for the class is shown in Listing 3 (p. 1693) .

Listing 3 - Beginning of the Prob03Runner class.

```
class Prob03Runner{
public Prob03Runner(){
    System.out.println("Dick Baldwin");
} //end constructor
```

Table 4.244

As you can see, the constructor simply displays the student's name, providing some of the text output shown in Figure 3 (p. 1693) .

Beginning of the run method

The beginning of the **run** method is shown in Listing 4 (p. 1694) . This is where things start to get interesting.

Listing 4 - Beginning of the run method.

```

    public void run(){
//This reference must be final because it is
// referenced from within an anonymous class
// definition.
final World world = new World(200,300);

//Get a reference to the JFrame object that is used
// to display the World.
JFrame frame = world.getFrame();

//Instantiate a new JButton object and add it to the
// SOUTH location in the JFrame object.
JButton button = new JButton(
    "Click to make a turtle.");
frame.getContentPane().add(button, BorderLayout.SOUTH);

frame.pack();//VERY IMPORTANT

```

Table 4.245

A new World object

Listing 4 (p. 1694) begins by instantiating a new object of the **World** class with a size of 200x300 pixels. The reference to the object is saved in a **final** variable named **world**.

A final reference variable

As the comment indicates, the variable must be **final** because it is referenced from within an anonymous class definition. I won't take the time to explain that here. I will simply refer you to my website where I have published several tutorial modules on anonymous classes.

The size of the world...

The purpose of specifying the size of the world when it is instantiated is to implicitly specify the size of the **Picture** object that forms the background for the world.

The size of the picture actually matches the specified dimensions. Therefore the actual size of the world is a little larger than the specified dimensions due to the borders that surround the picture.

Get a reference to the frame

After the **World** object is instantiated, the new **getFrame** method is called on the world's reference in order to get and save a reference to the frame.

A new JButton object

Then a new **JButton** object is instantiated. The reference to the **JButton** object is saved in the variable named **button**.

Add the button to the frame and pack it

Then the button is added to the **SOUTH** location in the frame and the **pack** method is called on the frame. Calling the **pack** method causes the size of the frame, (*and hence the size of the world*) to be adjusted so as to accommodate the picture in the **CENTER** of the frame and the button at the bottom (**SOUTH**) of the frame.

The final size of the world

After the button is added and the world is packed, the overall height of the world is quite a bit larger than the original dimensions. I measured it and found it to be about 209x361 pixels including borders.

The expansion in height is necessary to make room for the button. However, as you can see in Figure 3 (p. 1692) , the size of the picture remains at 200x300 pixels.

Register an action listener on the button

I elected to use an *anonymous class* to register an action listener on the button. The purpose of the listener is to produce the desired behavior when the button is clicked.

Note, however, that there are other ways to register an action listener on the button and the student is not required to use an anonymous class for that purpose.

Beginning of the anonymous class

The definition of the anonymous listener class and the instantiation of the listener object begins in Listing 5 (p. 1695) .

Listing 5 - Register an action listener on the button.

```
button.addActionListener(new ActionListener()
{//Begin the class definition

public void actionPerformed(ActionEvent e){
    Picture picture = world.getPicture();
    System.out.println(picture);
```

Table 4.246

Unfamiliar with anonymous classes?

If you are unfamiliar with anonymous classes and action listeners, I will simply refer you to my website where I have published several tutorial modules on the topic. I have also published modules on the topic in this collection.

In a nutshell...

In a nutshell, however, the method named **actionPerformed** , which begins in Listing 5 (p. 1695) , will be executed each time the user clicks the button in Figure 1 (p. 1690) .

Behavior of the actionPerformed method

The code in Listing 5 (p. 1695) gets and saves a reference to the **Picture** object that forms the background in the world object. Then it passes a copy of that reference to the **println** method, producing the third line of output text shown in Figure 3 (p. 1692) .

Set the background picture to blue

Listing 6 (p. 1695) calls the method named **setAllPixelsToAColor** on the **Picture** object passing the color **BLUE** as a parameter.

Listing 6 - Set the picture background to blue.

```
picture.setAllPixelsToAColor(Color.BLUE);
```

Table 4.247

As you might expect, this causes the background of the world to turn from white to blue as shown in Figure 2 (p. 1690) .

Display the student's name on the picture

Listing 7 (p. 1697) calls the **addMessage** method on the picture to add the student's name near the upper-left corner of the world. (See Figure 2 (p. 1690) .)

Listing 7 - Display the student's name on the picture.

```
picture.addMessage("Dick Baldwin",10,20);
```

Table 4.248

Finally, Listing 8 (p. 1697) instantiates a new **Turtle** object in the default color, with the default heading (*north*), located in the default position, which is the center of the picture that constitutes the background image for the world.

Listing 8 - Add a turtle to the world.

```

        Turtle turtle = new Turtle(world);
    }//end actionPerformed

    }//end class definition
);//end addActionListener

}//end run
//-----//
}//end class Prob03Runner
```

Table 4.249**Multiple clicks**

If you click the button more than once, you will instantiate a new **Turtle** object and produce a line of output text on the command line screen with each click. The turtles will all be in the same location but they will cycle through four different color schemes.

Note that adding the turtle to the world causes the world to be repainted, eliminating the requirement to purposely repaint the world.

End the run method

Finally, Listing 8 (p. 1697) signals the end of the **run** method, causing the **run** method to terminate and return control to the **main** method in Listing 2 (p. 1693). The **main** method terminates causing the program to terminate.

4.4.3.1.3.5 Run the program

I encourage you to copy the code from Listing 9 (p. 1698) and Listing 10 (p. 1699). Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.3.1.3.6 Summary

In this module, you learned how to incorporate GUI components into a **World** object. In particular, you learned how to add a **JButton** object to a **World** object and register an action listener on the button to control the behavior of the program.

4.4.3.1.3.7 What's next?

In the next module, you will learn how to modify the **SimplePicture** class to make it possible to control the color of the text that is placed on the image in a **Picture** object. Then you will place a turtle object in a world and perform a series of maneuvers causing the turtle to draw a square spiral.

4.4.3.1.3.8 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java OOP: Incorporating GUI Components into a World Object
- File: Java3106.htm
- Revised: 02/06/16

Disclaimers: Financial : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

In the past, unknown individuals have copied my modules from cnx.org, converted them to Kindle books, and placed them for sale on Amazon.com showing me as the author. I neither receive compensation for those sales nor do I know who does receive compensation. If you purchase such a book, please be aware that it is a copy of a module that is freely available on cnx.org and that it was made and published without my prior knowledge.

4.4.3.1.3.9 Complete program listing

Complete listings of the programs discussed in this module are provided below.

Listing 9 - Source code for the program named Prob03.

```
import java.awt.BorderLayout;
import javax.swing.JFrame;
import javax.swing.JButton;
import java.awt.event.ActionListener;
import java.awt.event.ActionEvent;
import java.awt.Color;

public class Prob03{
    public static void main(String[] args){
        new Prob03Runner().run();
    }//end main method
}//end class Prob03

//=====//
class Prob03Runner{
```

```

public Prob03Runner(){
    System.out.println("Dick Baldwin");
} //end constructor
//-----//
public void run(){
    //This reference must be final because it is
    // referenced from within an anonymous class
    // definition.
    final World world = new World(200,300);

    //Get a reference to the JFrame object that is used
    // to display the World.
    JFrame frame = world.getFrame();

    //Instantiate a new JButton object and add it to the
    // SOUTH location in the JFrame object.
    JButton button = new JButton(
        "Click to make a turtle.");
    frame.getContentPane().add(button, BorderLayout.SOUTH);

    frame.pack();//VERY IMPORTANT

    //Use an anonymous class to register an action
    // listener on the button. Note that the student is
    // not required to use an anonymous class.
    button.addActionListener(new ActionListener()
        { //Begin the class definition
            public void actionPerformed(ActionEvent e){
                Picture picture = world.getPicture();
                System.out.println(picture);
                //Set picture background to blue.
                picture.setAllPixelsToAColor(Color.BLUE);
                //Display the student's name on the picture.
                picture.addMessage(
                    "Dick Baldwin",10,20);
                //Add a turtle to the world. This causes the
                // world to be repainted.
                Turtle turtle = new Turtle(world);
            } //end actionPerformed
        } //end class definition
    ); //end addActionListener

} //end run
//-----//
} //end class Prob03Runner

4.4.3.1.4.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

The program described in this module requires the use of the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library⁴⁰⁸.

4.4.3.1.4.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

⁴⁰⁷This content is available online at <<http://cnx.org/content/m44351/1.5/>>.

4.4.3.1.4.2.1.1 Figures

- Figure 1 (p. 1706) . Output image at startup.
- Figure 2 (p. 1707) . Output image after ten mouse clicks.
- Figure 3 (p. 1708) . Output image after eleven mouse clicks.

4.4.3.1.4.2.1.2 Listings

- Listing 1 (p. 1709) . The new setMessageColor method.
- Listing 2 (p. 1711) . The modified addMessage method.
- Listing 3 (p. 1712) . Beginning of the Prob04Runner class.
- Listing 4 (p. 1713) . Beginning of the anonymous listener class.
- Listing 5 (p. 1713) . Add a turtle to the world.
- Listing 6 (p. 1714) . Not the first click.
- Listing 7 (p. 1715) . Process odd or even clicks.
- Listing 8 (p. 1716) . Cause the program to terminate properly.
- Listing 9 (p. 1717) . Source code for the program named Prob04.
- Listing 10 (p. 1719) . Modified World class.
- Listing 11 (p. 1724) . Modified SimplePicture class.

4.4.3.1.4.3 Preview

The program that I will explain in this module requires you to modify both the **World** class and the **SimplePicture** class from Ericson's media library.

Just as you did in an earlier module, you will modify the **World** class to make it possible to get access to the **JFrame** object that is encapsulated in a **World** object.

You will modify the **SimplePicture** class to make it possible to control the color of the text that is placed on the image in a **Picture** object.

Program specifications

Write a program named **Prob04** that uses the class definition for the **Prob04** class shown in Listing 9 (p. 1717) along with Ericson's media library to produce the graphic output images shown in Figure 1 (p. 1706) , Figure 2 (p. 1707) , and Figure 3 (p. 1708) .

Output image at startup

Figure 1 (p. 1706) shows the output image when you first start the program.

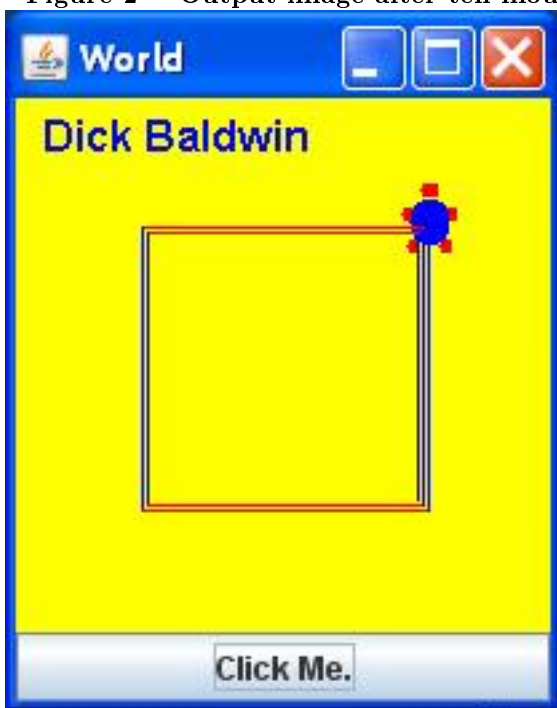

Figure 1 - Output image at startup.

Output image after ten mouse clicks

This program adds a **JButton** object to the SOUTH location of the **World** object as shown in Figure 1 (p. 1706) . Figure 2 (p. 1707) shows the output image after you click button ten times.

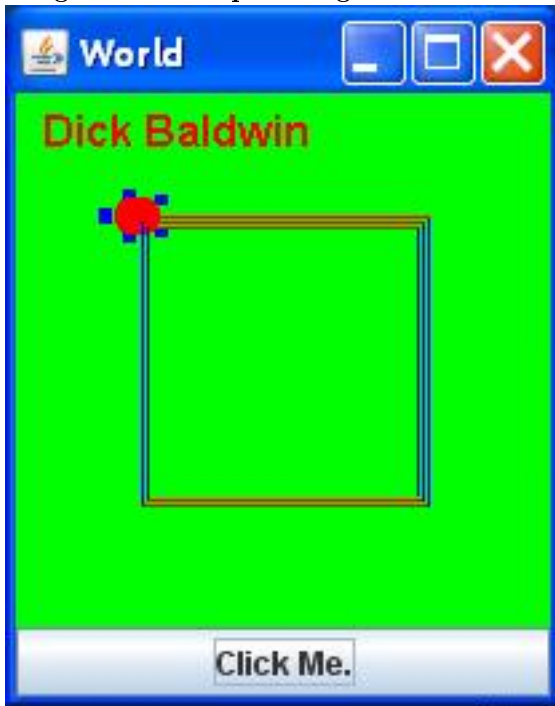

Figure 2 - Output image after ten mouse clicks.

Output image after eleven mouse clicks

Figure 3 (p. 1708) shows the output image after you click button eleven times.

Figure 3 - Output image after eleven mouse clicks.

Operational description

The program initially displays an empty white world with a button at the bottom as shown in Figure 1 (p. 1706) .

When the user clicks the button:

- The world's background color changes to green.
- A turtle appears near the bottom right corner of the World.
- The student's name appears near the top left corner of the world in red.
- The turtle has a blue body and a red shell.

Click the button again

When you click the button the second time:

- The background color changes to yellow.
- The student's name changes to blue.
- The turtle changes to a red body with a blue shell.
- The turtle turns 90 degrees left and moves forward 100 pixels plus the value of a click counter.
- The turtle leaves a blue trail.

Click the button another time

On the next click:

- The colors revert to the color scheme with the yellow background.
- The turtle turns 90 degrees left and moves forward 100 pixels plus the value of the click counter leaving a red trail.

Click the button repeatedly

This cycle repeats on each click with the turtle's trail drawing a square spiral of increasing size with red lines on the top and bottom of the spiral and blue lines on the right and left of the spiral.

Output text

In addition to the output images described above, your program must produce some output text on the command- line screen

4.4.3.1.4.4 Discussion and sample code**The driver class**

The driver class named **Prob04** is shown at the beginning of Listing 9 (p. 1717) near the end of the module. The **main** method simply instantiates a new object of the class named **Prob04Runner** , which I will explain later. The event driven behavior of the program is controlled by a listener object that is registered on the button in the constructor of the **Prob04Runner** class.

Modification of the World class

This program adds a method named **getFrame** to the **World** class. The method returns a reference to the **JFrame** object that is used to display the world.

The program uses that reference to add a **JButton** object to the SOUTH location of the **World** . I explained a modification very similar to this in an earlier module, so I won't repeat that explanation here.

A complete listing of the modified **World** class is provided in Listing 10 (p. 1719) near the end of the module.

Modification of the SimplePicture class

This program modifies the **addMessage** method of the **SimplePicture** class to cause it to use a color variable named **messageColor** to set the color of the text. The modification also declares and initializes the private instance variable named **messageColor** .

The **SimplePicture** class was also modified to include a **setMessageColor** method that can be used to set the color value stored in the variable named **messageColor** .

The new setMessageColor method

The new method named **setMessageColor** that was added to the **SimplePicture** class is shown in Listing 1 (p. 1709) .

Listing 1 - The new setMessageColor method.

```
public void setMessageColor(Color color){
    System.out.println("Dick Baldwin");
    messageColor = color;
} //end setMessageColor
```

Table 4.250**Save the color value**

The **setMessageColor** method saves the incoming color parameter in a private instance variable named **messageColor** that was added to the class.

The default value of the variable is **Color.WHITE** , thereby preserving the default behavior of the **addMessage** method.

You can view the new variable named **messageColor** in Listing 11 (p. 1724) near the end of the module.

Display the student's name

The new **setMessageColor** method also causes my name to be displayed each time the method is called. This is of no operational value, but is useful during the testing stage of the modified class. This is part of the code that produces text output on the command line screen.

The modified addMessage method

The modified version of the **addMessage** method is shown in Listing 2 (p. 1711) .

Listing 2 - The modified addMessage method.

```
public void addMessage(  
    String message, int xPos, int yPos){  
    // get a graphics context to use to draw on the  
    // buffered image  
    Graphics2D graphics2d = bufferedImage.createGraphics();  
  
    // set the color to white  
    //graphics2d.setPaint(Color.white);  
  
    //modified by Baldwin on 12/23/08  
    graphics2d.setPaint(messageColor);  
  
    // set the font to Helvetica bold style and size 16  
    graphics2d.setFont(new Font("Helvetica",Font.BOLD,16));  
  
    // draw the message  
    graphics2d.drawString(message,xPos,yPos);  
  
} //end addMessage
```

Table 4.251

The original statement shown in Listing 2 (p. 1711) was disabled and replaced by the statement shown following the modification comment. This causes the text to be displayed on the image using the color stored in the new private instance variable named **messageColor** .

The Prob04Runner class

I will explain this program in fragments. A complete listing is shown in Listing 9 (p. 1717) near the end of the module.

The driver class

The driver class for this program is named **Prob04** . As I mentioned earlier, you can view the class definition in its entirety near the beginning of Listing 9 (p. 1717) .

Beginning of the Prob04Runner class

The **Prob04Runner** class begins in Listing 3 (p. 1712) .

Listing 3 - Beginning of the Prob04Runner class.

```

class Prob04Runner{
Turtle turtle = null;
Picture picture = null;
int counter = 0;
World world = new World(200,200);
JButton button = new JButton("Click Me.");

public Prob04Runner(){
System.out.println("Dick Baldwin");
System.out.println(world.getPicture());

//Get a reference to the JFrame object that is used
// to display the World.
JFrame frame = world.getFrame();

//Add the JButton object to the
// SOUTH location in the JFrame object.
frame.getContentPane().add(button, BorderLayout.SOUTH);

frame.pack();
}
}

```

Table 4.252**Very familiar code**

You should already be familiar with all of the code in Listing 3 (p. 1712) . When the code in Listing 3 (p. 1712) has finished executing, the image shown in Figure 1 (p. 1706) should have appeared on the screen.

Waiting for an event

At this point, the program is essentially idle waiting for the user to either click the button at the bottom of Figure 1 (p. 1706) , or click the red X-button in the upper-right corner of Figure 1 (p. 1706) . (*More on the red X-button later.*)

Beginning of the anonymous listener class

This program uses an anonymous inner class to register an action listener on the button. The anonymous class begins in Listing 4 (p. 1713) .

Listing 4 - Beginning of the anonymous listener class.

```

    button.addActionListener(new ActionListener()
    { //Begin the anonymous class definition

        public void actionPerformed(ActionEvent e){
            picture = world.getPicture();

            //Set picture background to green.
            picture.setAllPixelsToAColor(Color.GREEN);
            picture.setMessageColor(Color.RED);

            //Display the student's name on the picture.
            picture.addMessage("Dick Baldwin",10,20);
        }
    }

```

Table 4.253**The event handler method named actionPerformed**

Once the listener object is instantiated from the anonymous class and registered on the button, the method named **actionPerformed**, which begins in Listing 4 (p. 1713), will be executed each time the button is clicked.

Get a reference to the background picture

The **actionPerformed** method begins by getting and saving a reference to the **Picture** object that provides the background image for the **World** object. By default, all of the pixels in this image are white, as shown in Figure 1 (p. 1706).

Set the background color to green

Then the method calls Ericson's standard method named **setAllPixelsToAColor** method to set the color of all of the background pixels to green.

Display student's name in red

Following that, the method calls the new **setMessageColor** method to set the text color to red, and calls the modified **addMessage** method to display my name in red near the upper-left corner of the image. Figure 3 (p. 1708) shows an example of a green background and red text.

Add a turtle to the world

Listing 5 (p. 1713) tests to determine if the variable named **turtle** that was declared in Listing 3 (p. 1712) still contains null. If so, that means that this is the first time that the button has been clicked and the **Turtle** object has not yet been added to the world.

Listing 5 - Add a turtle to the world.

```

    if(turtle == null){
        turtle = new Turtle(150,150,world);
        turtle.setHeading(90);
        turtle.setShellColor(Color.RED);
        turtle.setBodyColor(Color.BLUE);
    }

```

Table 4.254

Add a Turtle object and set its colors

Listing 5 (p. 1713) instantiates a new **Turtle** object and adds it to the world near the lower-right corner facing due east (*90 degrees*) .

The shell color is set to red and the body color (*feet and head*) is set to blue. An example of the turtle with this color scheme is shown in Figure 3 (p. 1708) .

Not the first click

If the conditional clause in Listing 5 (p. 1713) returns false, that means that this is not the first time the button has been clicked and the else clause, which begins in Listing 6 (p. 1714) will be executed.

Listing 6 - Not the first click.

```

}else{
turtle.turnLeft();
turtle.forward(100+counter);

```

Table 4.255

Rotate and move

The **else** clause begins by causing the turtle to rotate to the left by a default angle of 90 degrees. Then the turtle moves forward by a distance equal to 100 plus the value of a counter that is incremented by one each time the button is clicked.

For example, on the second click of the button, the turtle moves toward the north drawing a blue line along the way. The default width of the line is one pixel and the default color of the line is the same as the shell color.

Process odd or even clicks

The behavior of the **actionPerformed** method at this point depends on whether the incremented value of the **counter** variable is even or odd. The code to accomplish this is shown in Listing 7 (p. 1715) .

Listing 7 - Process odd or even clicks.

```

        if(counter++ %2 != 0){
            picture.setAllPixelsToAColor(Color.GREEN);
            picture.setMessageColor(Color.RED);

            picture.addMessage(
                "Dick Baldwin",10,20);
            turtle.setShellColor(Color.RED);
            turtle.setBodyColor(Color.BLUE);
        }else{
            picture.setAllPixelsToAColor(Color.YELLOW);
            picture.setMessageColor(Color.BLUE);

            picture.addMessage(
                "Dick Baldwin",10,20);
            turtle.setShellColor(Color.BLUE);
            turtle.setBodyColor(Color.RED);
        }//end else

        picture.addMessage(
            "Dick Baldwin",10,20);
    }//end else

    }//end actionPerformed
} //end class definition
); //end addActionListener

} //end constructor
//-----//

} //end class Prob04Runner

```

Table 4.256**If the counter value is odd...**

If the value of the counter (*before it is incremented – note the post-increment operator*) is odd, the color scheme for the background, the message, and the turtle is set to that shown in Figure 3 (p. 1708) with the green background.

If the counter value is even...

Otherwise, if the counter value is even, the color scheme is set to that shown in Figure 2 (p. 1707) with the yellow background.

The end of several sections of code

Listing 7 (p. 1715) also completes the **else** clause that began in Listing 6 (p. 1714) .

In addition, Listing 7 (p. 1715) signals the end of the **actionPerformed** method, the end of the anonymous class definition, the end of the constructor, and the end of the class named **Prob04Runner** .

Waiting for an event

As mentioned earlier, once the constructor finishes execution, the program becomes idle waiting for the user to either click the button at the bottom of Figure 1 (p. 1706) , or click the red X-button in the

upper-right corner of Figure 1 (p. 1706) .

Does not terminate as expected

Normally a user would expect the program to terminate and return control to the operating system when the user clicks the red X-button in the upper-right corner of the last remaining window. However, this program does not do that. Instead, clicking this button simply hides the window and control is not returned to the operating system.

A programming oversight

This was a programming oversight on my part, which can be corrected by adding the second statement in Listing 8 (p. 1716) to the definition of the **Prob04Runner** class immediately following the first statement shown in Listing 8 (p. 1716) .

<p>Listing 8 - Cause the program to terminate properly.</p>
<pre> JFrame frame = world.getFrame(); frame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE); </pre>

Table 4.257

To understand why this is necessary to cause the program to terminate, I recommend that you visit the standard Sun javadocs and examine the description of the method named **setDefaultCloseOperation** in the **JFrame** class.

4.4.3.1.4.5 Run the program

I encourage you to copy the code from Listing 9 (p. 1717) , Listing 10 (p. 1719) , and Listing 11 (p. 1724) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.3.1.4.6 Summary

Just as you did in an earlier module, you modified the **World** class to make it possible to get access to the **JFrame** object that is encapsulated in a **World** object.

You learned how to modify the **SimplePicture** class to make it possible to control the color of the text that is placed on the image in a **Picture** object.

Then you placed a turtle object in a world and performed a series of maneuvers causing the turtle to draw a square spiral.

4.4.3.1.4.7 What's next?

In the next module, you will learn how to create and service a graphical user interface containing panels, labels, text fields, and buttons.

4.4.3.1.4.8 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java OOP: Background Color, Text Color, Mouse Clicks, etc.
- File: Java3108.htm

- Revised: 02/06/16

Disclaimers: Financial : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

In the past, unknown individuals have copied my modules from cnx.org, converted them to Kindle books, and placed them for sale on Amazon.com showing me as the author. I neither receive compensation for those sales nor do I know who does receive compensation. If you purchase such a book, please be aware that it is a copy of a module that is freely available on cnx.org and that it was made and published without my prior knowledge.

Affiliation : I am a professor of Computer Information Technology at Austin Community College in Austin, TX.

4.4.3.1.4.9 Complete program listings

Complete listings of the programs discussed in this module are shown below.

Listing 9 - Source code for the program named Prob04.

```

/*File Prob04 Copyright 2008 R.G.Baldwin

4.4.3.1.5.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

The program described in this module requires the use of the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library⁴¹⁰.

4.4.3.1.5.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

4.4.3.1.5.2.1.1 Figures

- Figure 1 (p. 1741) . Program output at startup.
- Figure 2 (p. 1742) . Program output after one click.
- Figure 3 (p. 1742) . Program output after several clicks.

4.4.3.1.5.2.1.2 Listings

- Listing 1 (p. 1744) . Beginning of the class named Prob05Runner.
- Listing 2 (p. 1744) . Instantiate GUI components.
- Listing 3 (p. 1745) . Beginning of the constructor.
- Listing 4 (p. 1746) . Add the six GUI components to the panel.
- Listing 5 (p. 1746) . Get the frame and add the panel to the frame.
- Listing 6 (p. 1747) . Set the background to blue and add a turtle.
- Listing 7 (p. 1747) . Define, instantiate, and register a listener on the Move button.
- Listing 8 (p. 1748) . Action listener to terminate the program.
- Listing 9 (p. 1749) . Source code for Prob05.

⁴⁰⁹This content is available online at <<http://cnx.org/content/m44352/1.6/>>.

⁴¹⁰<http://cnx.org/content/m44148/latest/>

4.4.3.1.5.3 Preview

In this module, you will learn how to create and service a graphical user interface containing panels, labels, text fields, and buttons.

Just as you did in earlier modules, you will modify the **World** class to make it possible to get access to the **JFrame** object that is encapsulated in a **World** object. However, because I explained those modifications to the **World** class in earlier modules, I won't repeat the explanation here. You can find a modified version of the World class in Java OOP: Background Color, Text Color, Mouse Clicks, etc. ⁴¹¹

Program specifications

Write a program named **Prob05** that uses the class definition named **Prob05** shown in Listing 9 (p. 1749) along with Ericson's media library to produce the graphic output images shown in Figure 1 (p. 1741) , Figure 2 (p. 1742) , and Figure 3 (p. 1742) .

Program output at startup

Figure 1 (p. 1741) shows the image that appears on the screen when the program first starts running.

Figure 1 - Program output at startup.

Program output after one click

⁴¹¹http://cnx.org/content/m44351/latest/#Listing_10

Figure 2 (p. 1742) shows the output image after the user enters the values shown into the two text fields and clicks the **Move** button once.

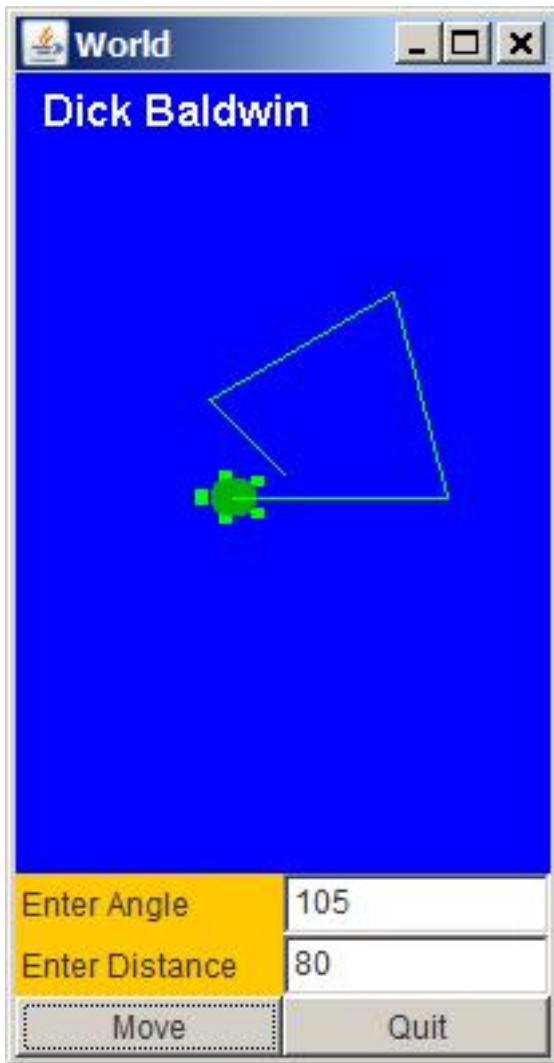

Figure 2 - Program output after one click.

Program output after several clicks

Figure 3 (p. 1742) shows the output image after the user enters several different sets of values into the text fields and clicks the **Move** button several times.

Figure 3 - Program output after several clicks.

Labels, text fields, and buttons

As shown in Figure 1 (p. 1741), this program adds two buttons, two labels, and two text fields to form a GUI at the bottom of the **World** object. Although it isn't obvious, those six components are contained in a **Panel** object.

Each time you enter numeric values into the angle and distance fields and then click the **Move** button, the turtle will turn by that angle in degrees and move by that distance in pixels.

Program termination

The program terminates and returns control to the operating system when the user clicks the **Quit** button.

Use AWT components instead of Swing components

The GUI at the bottom of the **World** object is comprised of **AWT** components instead of **Swing** components.

Required text output

In addition to the output image described above, your program must produce some rather inconsequential text output on the command-line screen.

4.4.3.1.5.4 Discussion and sample code

The class named Prob05

You can view the driver class named **Prob05** at the beginning of the source code in Listing 9 (p. 1749) . You are already familiar with the code in the **main** method of that class from earlier modules so I won't waste time explaining it.

Briefly, the **main** method instantiates a new object of the class named **Prob05Runner** . Once that object is instantiated, the program goes idle waiting for an event to happen. Events happen when the user enters text into the text fields or presses one of the buttons shown in Figure 1 (p. 1741) .

The class named Prob05Runner

I will explain this program in fragments. A complete listing of the program is provided in Listing 9 (p. 1749) near the end of the module

The class named **Prob05Runner** begins in Listing 1 (p. 1744) .

Listing 1 - Beginning of the class named Prob05Runner.

```
class Prob05Runner{
Turtle turtle = null;
Picture picture = null;
World world = new World(200,300);
```

Table 4.258

There's nothing new in Listing 1 (p. 1744) . You have seen code like this in several earlier modules.

Instantiate GUI components

Listing 2 (p. 1744) instantiates the GUI components that are used to construct the GUI at the bottom of Figure 1 (p. 1741) .

Listing 2 - Instantiate GUI components.

```
Panel mainPanel = new Panel();
Label angleLabel = new Label("Enter Angle");
TextField angleField = new TextField("000");
Label distanceLabel = new Label("Enter Distance");
TextField distanceField = new TextField("000");
Button moveButton = new Button("Move");
Button quitButton = new Button("Quit");

int angle = 0;
int distance = 0;
```

Table 4.259

References to the GUI components are saved in instance variables with descriptive names.

GUI component initialization

Except for the **Panel** object, each GUI component is initialized with information that is appropriate to the type of component. Compare the initialization values in Listing 2 (p. 1744) with the image in Figure 1 (p. 1741) for a better understanding of what I mean by this.

Brief description of the GUI components

You are encouraged to visit the Sun Java documentation and read about the following AWT components:

- **Panel** : A panel provides space in which an application can attach any other components, including other panels.
- **Label** : A Label object is a component for placing text in a container. A label displays a single line of read-only text. The text can be changed by the application, but a user cannot edit it directly.
- **TextField** : A text component that allows for the editing of a single line of text.
- **Button** : This class creates a labeled button. The application can cause some action to happen when the button is pushed.

Figure 1 (p. 1741) contains a **Panel** object at the bottom. The panel contains two **Label** objects (*shown as orange*), two **TextField** objects (*white*), and two **Button** objects (*gray*). Those seven objects are instantiated in Listing 2 (p. 1744).

The angle and distance variables

Listing 2 (p. 1744) also declares and initializes two instance variables named **angle** and **distance**. (Note that these two variables would be automatically initialized to zero if I didn't initialize them, but I prefer to initialize them explicitly in order to make the code more self-documenting.)

Beginning of the constructor

The constructor for the class named **Prob05Runner** begins in Listing 3 (p. 1745).

Listing 3 - Beginning of the constructor.

```
public Prob05Runner(){
    System.out.println("Dick Baldwin");

    mainPanel.setBackground(Color.ORANGE);

    mainPanel.setLayout(new GridLayout(0,2));
```

Table 4.260

The constructor begins by displaying my name on the command line screen. This is inconsequential insofar as the overall operation of the program is concerned.

Set the panel background color to orange

Then Listing 3 (p. 1745) sets the background color of the panel to orange. This is what causes the two labels in Figure 1 (p. 1741) to appear to be orange. They are actually transparent except for the text. The orange color shows through causing the labels to appear to be orange.

Set the layout to GridLayout

Setting the layout manager controls how the components that are placed in the panel will be arranged. A **GridLayout** causes all components to be the same size arranged in rows and columns.

Overloaded constructors

There are several overloaded versions of the **GridLayout** constructor. For the constructor used in Listing 3 (p. 1745), the parameters specify the number of rows and the number of columns in that order. Specifying the number of rows as 0 and the number of columns as 2 means that the layout manager will accept any number of rows but only two columns.

The order of component placement

The intersections of the rows and columns create **cells**. Components are placed in the cells in left to right, top to bottom order as they are added to the panel.

Add the six GUI components to the panel

Listing 4 (p. 1746) adds the six GUI components to the panel in the left to right, top to bottom order described above.

Listing 4 - Add the six GUI components to the panel.

```
mainPanel.add(angleLabel);
mainPanel.add(angleField);
mainPanel.add(distanceLabel);
mainPanel.add(distanceField);
mainPanel.add(moveButton);
mainPanel.add(quitButton);
```

Table 4.261

At this point, the panel has been populated with GUI components, but the panel itself has not been added to the **JFrame** object that forms the **World** object. That is accomplished in Listing 5 (p. 1746).

Get the frame and add the panel to the frame

Listing 5 (p. 1746) gets a reference to the **World** object's frame and adds the panel to the SOUTH location in that frame.

Listing 5 - Get the frame and add the panel to the frame.

```
JFrame frame = world.getFrame();
frame.getContentPane().add(
    mainPanel, BorderLayout.SOUTH);

frame.pack();
```

Table 4.262

You can surmise from the word SOUTH that the panel is added to the bottom of the frame. To learn more about this, visit the **BorderLayout** class in Sun's Java documentation.

Pack the frame

As you learned in an earlier module, it is very important that you pack the frame at this point. Packing the frame causes the frame to adjust its dimensions in order to accommodate all of the components that have been added to it. In this case, the frame contains a **Picture** object (*placed there when the **World** was constructed*) and a **Panel** object placed there in Listing 5 (p. 1747).

What about the size of the panel?

Exactly how the panel decides what size it needs to be to accommodate the six GUI components is a fairly complicated topic, so I won't go into it here. However, if you do much work developing GUIs, you definitely need to understand the process. I have explained the automatic sizing process in several tutorials on my website.

Set the background to blue and add a turtle

Listing 6 (p. 1747) sets the background color of the world to blue and adds a turtle to the world.

Listing 6 - Set the background to blue and add a turtle.

```

//Initialize the picture.
picture = world.getPicture();
//Set picture background to BLUE
picture.setAllPixelsToAColor(Color.BLUE);
//Display the student's name on the picture.
picture.addMessage("Dick Baldwin",10,20);
//Add a turtle to the world. This causes the
// world to be repainted.
turtle = new Turtle(world);

```

Table 4.263

There is nothing new in Listing 6 (p. 1747) . I have explained code very similar to this code in earlier modules.

Could stop at this point

If we were to stop programming at this point, the program would be executable, and would produce the output shown in Figure 1 (p. 1741) when it is run. However it would be completely passive. By that, I mean that entering values into the text fields and clicking the buttons at the bottom of Figure 1 (p. 1741) would have no effect. However, the buttons would appear to be active from a visual viewpoint because the animation behavior is built into objects of the **Button** class.

Register listener objects

In order to cause the buttons to impact the behavior of the program, we must instantiate and register listener object on the buttons. I will do that using anonymous classes.

Define, instantiate, and register a listener on the Move button

The code in Listing 7 (p. 1747) :

- Defines an anonymous **ActionListener** class.
- Instantiates an anonymous object of that class.
- Registers that object on the **Move** button

Listing 7 - Define, instantiate, and register a listener on the Move button.

```

moveButton.addActionListener(
new ActionListener(){

public void actionPerformed(ActionEvent e){
angle = Integer.parseInt(angleField.getText());
distance = Integer.parseInt(
distanceField.getText());

turtle.turn(angle);
turtle.forward(distance);
};//end action performed

};//end newActionListener
);//end addActionListener

```

Table 4.264

The actionPerformed method

As you learned in an earlier module, the code in the `actionPerformed` method is executed each time the user presses the **Move** button.

The `actionPerformed` method in Listing 7 (p. 1747) begins by getting the text from each of the text fields, converting the text to type `int`, and saving the `int` values in the variables named `angle` and `distance`.

Then Listing 7 (p. 1747) calls the `turn` and `forward` methods of the `Turtle` class to cause the turtle to turn by the specified angle and then move forward by the specified distance.

Action listener to terminate the program

Listing 8 (p. 1748) registers an action listener on the **Quit** button, which will cause the program to terminate when the user clicks the button.

Listing 8 - Action listener to terminate the program.

```

quitButton.addActionListener(
new ActionListener(){
public void actionPerformed(ActionEvent e){

    System.exit(0);

    }//end action performed
};//end newActionListener
);//end addActionListener

};//end constructor
//-----//

};//end class Prob05Runner

```

Table 4.265

As you can see in Listing 8 (p. 1748), this code causes the `exit` method of the `System` class to be called when the user clicks the **Quit** button. According to the Sun documentation, a call to the `exit` method *"Terminates the currently running Java Virtual Machine."*

The end of the constructor and the end of the class

Listing 8 (p. 1748) also shows the end of the constructor for the `Prob05Runner` class and the end of the class.

4.4.3.1.5.5 Run the program

I encourage you to copy the code from Listing 9 (p. 1749). Compile the code and execute it. Experiment with the code, making changes and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.3.1.5.6 Summary

In this module, you learned how to create and service a graphical user interface containing panels, labels, text fields, and buttons.

4.4.3.1.5.7 What's next?

In the next module, you will learn about:

- Alpha transparency
- A buffered image of type `TYPE_INT_ARGB`
- The ability to use the `getBasicPixel` and `setBasicPixel` methods,
- The use of the bitwise AND and OR operators,
- The use of the `drawImage` method of the `Graphics` class.

4.4.3.1.5.8 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java OOP: Panels, Labels, Text Fields, and Buttons
- File: Java3110.htm
- Revised: 02/06/16

Disclaimers: Financial : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

In the past, unknown individuals have copied my modules from `cnx.org`, converted them to Kindle books, and placed them for sale on Amazon.com showing me as the author. I neither receive compensation for those sales nor do I know who does receive compensation. If you purchase such a book, please be aware that it is a copy of a module that is freely available on `cnx.org` and that it was made and published without my prior knowledge.

Affiliation : I am a professor of Computer Information Technology at Austin Community College in Austin, TX.

4.4.3.1.5.9 Complete program listing

A complete listing of the program discussed in this lesson is shown in Listing 9 (p. 1749) below.

Listing 9 - Source code for Prob05.

4.4.3.2.1.3 Preview

The primary objective of this module is to incorporate alpha transparency into the use of Ericson's media library.

Two approaches

There are at least two ways to incorporate alpha transparency into Ericson's media library, The easiest way, which is not necessarily the best way, is to make a relatively simple modification to a constructor in Ericson's **SimplePicture** class. That is the approach used in this module.

The second approach

⁴¹³<http://cnx.org/content/m44148/latest/>

The second approach is more complicated, but does not require the modification of the classes in Ericson's library. That is probably a better approach due simply to the fact that modifications to Ericson's library are not required. However, that approach is not shown in this module.

Outside research

This program may require a significant amount of outside research on the part of the student in order to learn about:

- Alpha transparency
- A buffered image of type `TYPE_INT_ARGB`
- The ability to use Ericson's `getBasicPixel` and `setBasicPixel` methods,
- The use of the bitwise AND and OR operators, and
- The use of the `drawImage` method of the `Graphics` class.

The `getBasicPixel` and `setBasicPixel` methods

The program uses the `getBasicPixel` and `setBasicPixel` methods from Ericson's library along with bitwise operations to set the alpha value for all the pixels in a cropped and flipped image of a butterfly to a hexadecimal value of 5F.

Modification to the `SimplePicture` class

The student must modify the `SimplePicture` class to cause the buffered image used to store the image to be `TYPE_INT_ARGB` instead of `TYPE_INT_RGB`, which is its normal type.

Crop, flip, and set alpha values

Then the student must write a method that will crop and flip an image of a butterfly and set the value of every alpha byte to a hexadecimal value of 5F.

Draw a partially transparent image of a butterfly

Finally, the student must use the standard `drawImage` method of the `Graphics` class to draw the image of the butterfly onto an image of a beach with transparency.

Brief program specifications

Write a program named `Prob06` that uses the class definition for the class named `Prob06` in Listing 7 (p. 1764) along with Ericson's media library and the image files named `Prob06a.jpg`⁴¹⁴ and `Prob06b.jpg`⁴¹⁵ to produce the three graphic output images shown in Figure 1 (p. 1753), Figure 2 (p. 1754), and Figure 3 (p. 1755).

Figure 1 - Image from file named `Prob06a`.

⁴¹⁴<http://cnx.org/content/m44911/latest/Prob06a.jpg>

⁴¹⁵<http://cnx.org/content/m44911/latest/Prob06b.jpg>

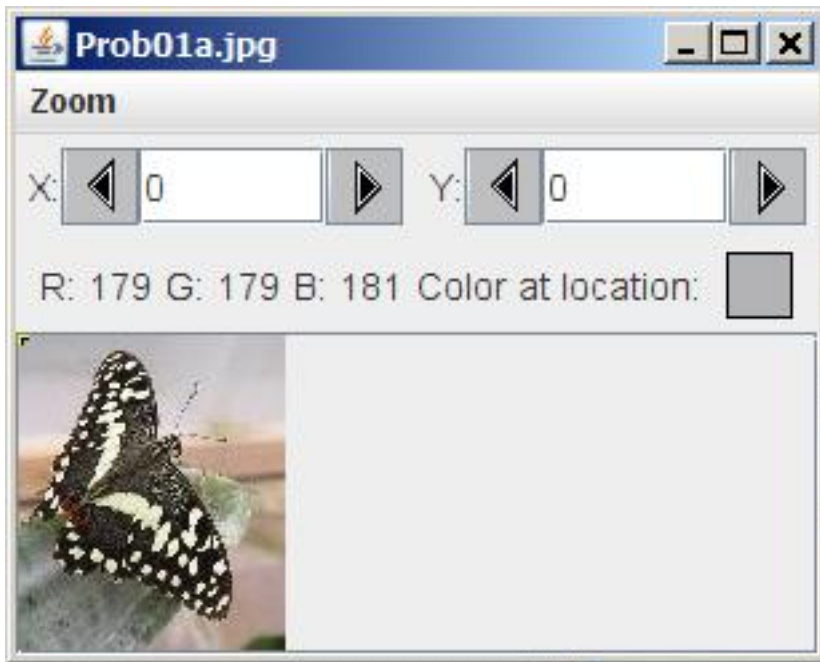

Figure 2 - Image from file named Prob06b.

Figure 3 - Processed output image.

Define new classes

You may define new classes as necessary to cause your program to behave as required, but you may not modify the class definition for the class named **Prob06** given in Listing 7 (p. 1764) .

A partially transparent image of a butterfly

Just in case you haven't noticed it, the final image of the beach contains a partially transparent image of a butterfly superimposed and centered on the beach image.

Modification to the SimplePicture class

In order to write this program, you will need to modify the class from Ericson's media library named **SimplePicture** .

Your modifications must make it possible for you to display a partially transparent image on top of another image with the background image showing through.

Transparency

The degree of transparency can range from being completely transparent at one extreme to being totally opaque at the other extreme. In this case, the butterfly image shown in Figure 3 (p. 1755) is about 37-percent opaque (*or 63-percent transparent*) .

Outside research

You will probably need to do some outside research in order to write this program. For example, you will need to learn about the following topics and probably some other topics as well:

- Alpha transparency
- BufferedImage objects of TYPE_INT_ARGB
- The representation of a pixel as type int
- Bit manipulation of pixels
- The drawImage method of the Graphics class

Required text output

In addition to the output images described above, your program must produce the text output shown in Figure 4 (p. 1757) on the command- line screen.

Figure 4 - Required text output.

```
Dick Baldwin.  
Dick Baldwin  
Picture, filename Prob06a.jpg height 118 width 100  
Picture, filename Prob06b.jpg height 240 width 320  
Picture, filename None height 101 width 77
```

Table 4.266

You must substitute your name for my name wherever my name appears both in the images and on the command-line screen.

4.4.3.2.1.4 General background information

The image in a **SimplePicture** object is stored in an object of the **BufferedImage** class, which is a class in the standard Sun Java library.

Image data formats

An examination of the documentation for the **BufferedImage** class shows that the red, green, blue, and alpha values for each pixel can be formatted in about fourteen different ways in an object of the **BufferedImage** class.

No alpha data

Some of those formats, including the way that information is stored in a **SimplePicture** object, don't include an alpha value.

Modification of the SimplePicture class

One way to modify the **SimplePicture** class to force it to accommodate alpha transparency data is to modify one of the constructors for the **SimplePicture** class as shown in Listing 1 (p. 1758) . Note that **BufferedImage.TYPE_INT_RGB** was replaced by **BufferedImage.TYPE_INT_ARGB** in Listing 1. (*There are probably other ways that you can modify the class to achieve the same result as well.*)

Listing 1 - Modification of the SimplePicture class.

```

    /**
    * A constructor that takes the width and height desired
    * for a picture and creates a buffered image of that
    * size. This constructor doesn't show the picture.
    */
    public SimplePicture(int width, int height){
//Disable the following statement
//    bufferedImage = new BufferedImage(
//        width, height, BufferedImage.TYPE_INT_RGB);

//Modify constructor to support alpha transparency.
System.out.println("Dick Baldwin");
bufferedImage = new BufferedImage(
    width, height, BufferedImage.TYPE_INT_ARGB);

    title = "None";
    fileName = "None";
    extension = ".jpg";
    setAllPixelsToAColor(Color.white);
} //end constructor

```

Table 4.267**Future Picture objects will accommodate alpha transparency**

Having made this modification, future objects instantiated from the **SimplePicture** class using this constructor will accommodate alpha transparency. (*The **SimplePicture** class is the superclass of the **Picture** class.*)

Display the student's name

Note that the constructor in Listing 1 (p. 1758) is also modified to cause it to display the student's name, which is a requirement of the program.

No complete listing of SimplePicture provided

Because of the simplicity of this modification, a complete listing of the modified **SimplePicture** class will not be provided in this module.

4.4.3.2.1.5 Discussion and sample code**4.4.3.2.1.5.1 The class named Prob06**

You can view the driver class named **Prob06** at the beginning of the source code in Listing 7 (p. 1764) . You are already familiar with the code in the **main** method of that class from earlier modules so I won't spend any time explaining it.

Briefly, the **main** method instantiates a new object of the class named **Prob06Runner** and calls the **run** method on that object. When the **run** method returns, the code in the **main** method displays some information about the three images and terminates.

(*Because there are images on the screen, the program does not actually terminate until the user forces it to terminate.*)

4.4.3.2.1.5.2 The class named Prob06Runner

Will explain in fragments

I will explain this program in fragments. A complete listing of the program is provided in Listing 7 (p. 1764) near the end of the module

The class named **Prob06Runner** begins in Listing 2 (p. 1759) , which shows the constructor for the class.

Listing 2 - Beginning of the class named Prob06Runner.

```
class Prob06Runner{

public Prob06Runner(){//constructor
    System.out.println("Dick Baldwin.");
} //end constructor
```

Table 4.268

The constructor simply displays the student's name to satisfy one of the requirements of the program.

The run method

The run method, which is called from the **main** method in Listing 7 (p. 1764) , is shown in its entirety in Listing 3 (p. 1759) .

Listing 3 - The run method.

```
public Picture[] run(){
//Insert executable code here
Picture picA = new Picture("Prob06a.jpg");
picA.explore();
Picture picB = new Picture("Prob06b.jpg");
picB.addMessage("Dick Baldwin.",10,20);
picB.explore();

Picture picC = cropAndFlip(picA,4,5,80,105);

copyPictureWithCrop(picC,picB,122,70);

picB.show();

Picture[] output = {picA,picB,picC};
return output;
} //end run
```

Table 4.269

New material

The only thing in Listing 3 (p. 1759) that is new to this module is the pair of calls to the following methods. I will explain these methods in the paragraphs that follow:

- **cropAndFlip**
- **copyPictureWithCrop**

Beginning of the **cropAndFlip** method

The **cropAndFlip** method begins in Listing 4 (p. 1760) . This method receives an incoming reference to a **Picture** object. It crops the picture to a set of specified coordinate values and flips it around a vertical line at its center.

Listing 4 - Beginning of the **cropAndFlip method.**

```
private Picture cropAndFlip(
    Picture pic,int x1,int y1,int x2,int y2){
Picture output = new Picture(x2-x1+1,y2-y1+1);

int width = output.getWidth();
Pixel pixel = null;
Color color = null;
for(int col = x1;col < (x2+1);col++){
    for(int row = y1;row < (y2+1);row++){
        color = pic.getPixel(col,row).getColor();
        pixel = output.getPixel(width-col+x1-1,row-y1);
        pixel.setColor(color);
    }//end inner loop
} //end outer loop
```

Table 4.270

Receives a reference to the butterfly image

Note from Listing 3 (p. 1759) that the **cropAndFlip** method receives a reference to the **Picture** object of the butterfly that is displayed in Figure 1 (p. 1753) .

Also note that the butterfly in Figure 1 (p. 1753) is facing toward the right while the butterfly in the output image in Figure 3 (p. 1755) has been cropped to a smaller size and is facing toward the left.

Crop and flip is not new

The capability to crop and flip an image is not new to this module. However, the **cropAndFlip** method also makes the image partially transparent as shown in Figure 3 (p. 1755) . That capability is new to this module. I will explain how that is done shortly.

A call to the modified **SimplePicture** constructor

Although there is nothing new in the code in Listing 4 (p. 1760) , it is important to note that the first statement in Listing 4 (p. 1760) causes the **SimplePicture** constructor that was modified in Listing 1 (p. 1758) to be called.

As a result, the **Picture** object referred to by the reference variable named **output** in Listing 4 (p. 1760) will accommodate alpha transparency data.

Make the pixels partially transparent

The code in Listing 5 (p. 1761) uses a pair of nested **for** loops to iterate through all of the pixels in the picture referred to by **output** and modify each pixel.

The four statements in the body of the inner loop in Listing 5 (p. 1761) cause the current pixel to become partially transparent.

Listing 5 - Make the pixels partially transparent.

```

        width = output.getWidth();
    int height = output.getHeight();
    pixel = null;
    color = null;
    for(int col = 0;col < width;col++){
        for(int row = 0;row < height;row++){

            int basicPixel = output.getBasicPixel(col,row);

            basicPixel = basicPixel & 0x00FFFFFF;
            basicPixel = basicPixel | 0x5F000000;

            output.setBasicPixel(col,row,basicPixel);

        }//end inner loop
    }//end outer loop

    return output;
} //end crop and flip

```

Table 4.271**The getBasicPixel method**

According to Ericson's documentation, the `getBasicPixel` method will *"return the pixel value as an int for the given x and y location."* In other words, a call to the `getBasicPixel` method will return an `int` value containing the red, green, blue, and alpha values for the pixel at the specified location.

A bitwise AND operation

Listing 5 (p. 1761) uses a bitwise **AND** operation (*note the single ampersand*) to force the eight most significant bits (*the alpha byte*) in the `int` representation of the current pixel to zero while preserving the bit values stored in the least significant 24 bits.

A bitwise OR operation

Then Listing 5 (p. 1761) uses a bitwise **OR** operation (`|`) to store the hexadecimal value 5F in the eight most significant bits (*the alpha byte*) without changing the values stored in the 24 least significant bits.

The alpha byte

The value of the alpha byte can range from 0 to 255. When rendered using a mechanism that supports alpha transparency, an alpha value of zero causes the pixel to be totally transparent.

Similarly, an alpha value of 255 causes the pixel to be totally opaque.

Values between zero and 255 cause the pixel to be rendered as partially opaque or partially transparent, whichever terminology you prefer.

Thirty-seven percent opaque

If I did the arithmetic correctly, a hexadecimal value of 5F represents a decimal value of 95. Therefore, this value will cause the pixel to be about 37-percent opaque (*or 63-percent transparent*) .

The setBasicPixel method

As the name implies, the `setBasicPixel` method can be used to *"set the value of a pixel in the picture from an int."*

Therefore, the last statement in the body of the inner loop in Listing 5 (p. 1761) replaces the value of the current pixel with the modified value containing a value of 95 in the alpha byte.

The end of the `cropAndFlip` method

When the pair of nested `for` loops in Listing 5 (p. 1761) terminates, the `cropAndFlip` method returns control to the `run` method in Listing 3 (p. 1759), returning a copy of the reference from the variable named `output` (see Listing 4 (p. 1760)) in the process.

Save the `Picture` object's reference

The returned reference is stored in the reference variable named `picC` in Listing 3 (p. 1759).

At this point, `picC` contains a reference to a butterfly image that has been cropped, flipped, and formatted into a buffered image that contains alpha transparency information.

Call the `copyPictureWithCrop` method

Listing 3 (p. 1759) immediately calls the `copyPictureWithCrop` method passing copies of the references stored in `picC` and `picB` along with a pair of integer coordinate values.

The `copyPictureWithCrop` method

The `copyPictureWithCrop` method is shown in its entirety in Listing 6 (p. 1762).

Listing 6 - The `copyPictureWithCrop` method.

```
private void copyPictureWithCrop(
    Picture source,Picture dest,int xOff,
    int yOff){

    Graphics destGraphics = dest.getGraphics();
    Image sourceImage = source.getImage();
    destGraphics.drawImage(sourceImage,
        xOff,
        yOff,
        null);
} //end copyPictureWithCrop method
} //end class Prob06Runner
```

Table 4.272

The purpose of the `copyPictureWithCrop` method is to copy a source picture onto a destination picture with an offset on each axis.

An exercise for the student

I won't attempt to explain the code in Listing 6 (p. 1762) in this module. Instead, I will simply suggest that you go to Google and search for the following or similar keywords:

baldwin java drawImage

You will find many tutorials that I have written that deal with topics in this area.

Modify the destination pixel colors

I will tell you that the use of the `drawImage` method in Listing 6 (p. 1762) modifies the destination picture in such a way that the color of each pixel in the resulting image is a combination of the colors in the original destination image and the corresponding pixel in the source image.

An illusion of transparency

If a source pixel is totally transparent, it has no effect on the color of the destination pixel.

If the source pixel is totally opaque, the color of the destination pixel is changed to the color of the source pixel.

For alpha values between these two extremes, the final color of the destination pixel produces the illusion of a partially transparent image in front of the original destination image.

Termination of the `copyPictureWithCrop` method

When the `copyPictureWithCrop` method terminates in Listing 6 (p. 1762) , control returns to the `run` method in Listing 3 (p. 1759) .

Listing 3 (p. 1759) calls the `show` method to display the image in the now-modified `Picture` object referred to by `picB` , as shown in Figure 3 (p. 1755) .

Return a reference to an array object

Then the `run` method encapsulates references to each of the three images in an array object and returns control to the `main` method in Listing 7 (p. 1764) , returning a copy of the array object's reference in the process.

The `main` method in Listing 7 (p. 1764) displays information about each of the three `Picture` objects, producing the output shown in Figure 4 (p. 1757) . Then the main method terminates.

Images don't go away immediately

Because there are images belonging to the program still on the screen, the program doesn't return control to the operating system. It will simply wait until it is forced to terminate by the user before returning control to the operating system.

Clicking the X-buttons in the upper-right corners of the images will simply hide the frames and won't terminate the program. Some extra work is required to deal with this issue.

4.4.3.2.1.6 Run the program

I encourage you to copy the code from Listing 7 (p. 1764) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.3.2.1.7 Summary

In this module, you learned about:

- Alpha transparency
- A buffered image of type `TYPE_INT_ARGB`
- The ability to use the `getBasicPixel` and `setBasicPixel` methods,
- The use of the bitwise AND and OR operators,
- The use of the `drawImage` method of the `Graphics` class.

You modified the `SimplePicture` class to cause the buffered image used to store the image to be `TYPE_INT_ARGB` instead of `TYPE_INT_RGB`, which is its normal type.

You wrote a method that cropped and flipped an image of a butterfly.

You used the `getBasicPixel` and `setBasicPixel` methods from Ericson's library along with bitwise operations to set the alpha value for all the pixels in the cropped and flipped image of the butterfly to a hexadecimal value of 5F.

Finally, you used the standard `drawImage` method of the `Graphics` class to draw the image of the butterfly onto an image of a beach with transparency.

4.4.3.2.1.8 What's next?

In the next module, you will learn how to use a slider to continuously change the opacity of an image and to draw that modified image onto a background image.

4.4.3.2.1.9 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

4.4.3.2.2.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

The program described in this module requires the use of the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library⁴¹⁷.

4.4.3.2.2.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

⁴¹⁶This content is available online at <<http://cnx.org/content/m44912/1.8/>>.

⁴¹⁷<http://cnx.org/content/m44148/latest/>

4.4.3.2.2.1.1 Figures

- Figure 1 (p. 1768) . Screen output at startup.
- Figure 2 (p. 1768) . Twenty-percent opacity.
- Figure 3 (p. 1769) . Eighty-percent opacity.

4.4.3.2.2.1.2 Listings

- Listing 1 (p. 1772) . Modification of the SimplePicture class.
- Listing 2 (p. 1773) . Beginning of the class named Prob07Runner.
- Listing 3 (p. 1774) . Beginning of the constructor.
- Listing 4 (p. 1774) . Display the initial image.
- Listing 5 (p. 1776) . Display the butterfly at 50-percent opacity.
- Listing 6 (p. 1776) . The setOpacity method.
- Listing 7 (p. 1777) . The drawPictureOnPicture method.
- Listing 8 (p. 1778) . Begin the registration of an event handler on the slider.
- Listing 9 (p. 1779) . Draw the butterfly and repaint.
- Listing 10 (p. 1780) . Complete program listing.

4.4.3.2.2.3 Preview

The primary objective of this module is to illustrate how to use a slider to continuously change the opacity of an image and to draw that image onto a background image.

Two approaches

This module builds on an earlier module involving transparency. In that module, you learned that there are at least two ways to incorporate alpha transparency into Ericson's media library, The easiest way, which is not necessarily the best way, is to make a relatively simple modification to a constructor in Ericson's **SimplePicture** class. That is the approach used in this module.

The second approach

The second approach is more complicated, but does not require the modification of the classes in Ericson's library. That is probably a better approach due simply to the fact that modifications to Ericson's library are not required. However, that approach is not shown in this module.

Outside research

As with the earlier module, the program that I will explain in this module may require a significant amount of outside research on the part of the student in order to learn about:

- Alpha transparency
- A buffered image of type **TYPE_INT_ARGB**
- The ability to use Ericson's **getBasicPixel** and **setBasicPixel** methods,
- The use of the bitwise AND, OR, and left-shift operators.
- The use of the **drawImage** method of the **Graphics** class.

Modification to the SimplePicture class

The student must modify the **SimplePicture** class to cause the buffered image used to store the image to be **TYPE_INT_ARGB** instead of **TYPE_INT_RGB** , which is its normal type.

Generally speaking, this program:

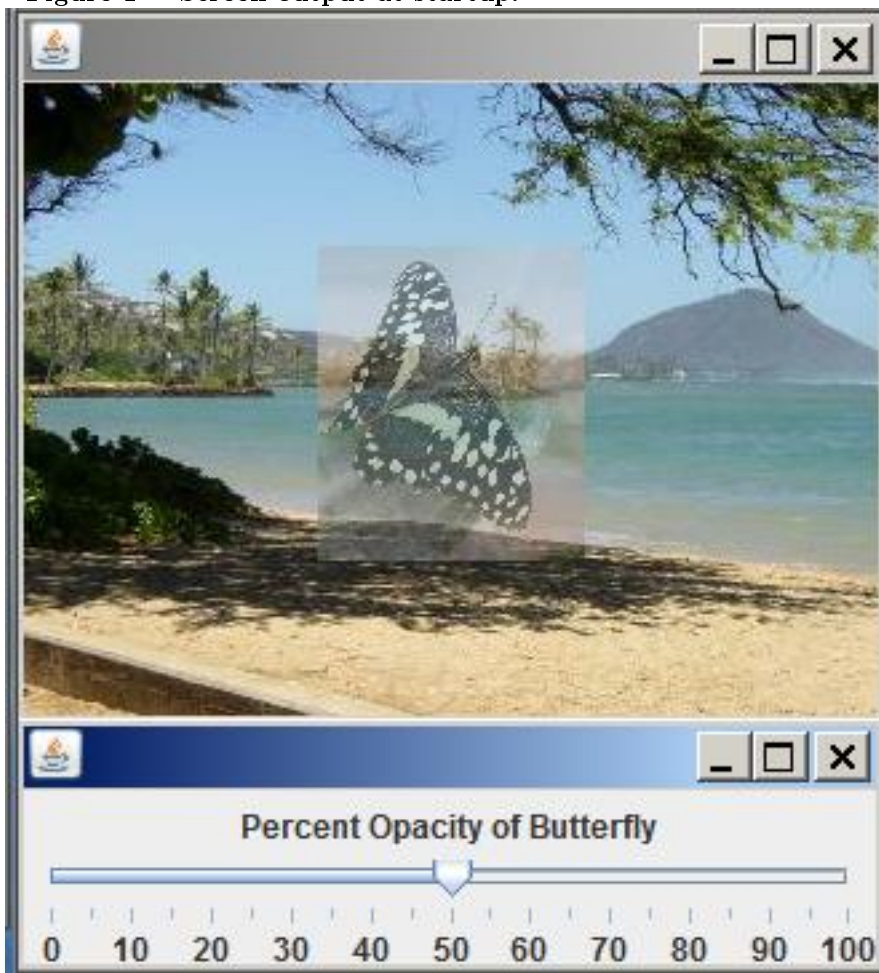

- Instantiates a new visual object that extends the **JFrame** class and contains a **JSlider** object.
- Instantiates **Picture** objects from two image files (*beach* and *butterfly*) along with some blank **Picture** objects of the same size.
- Defines a method named **setOpacity** that can be called to set the opacity of every pixel in a picture to a specified value.

- Defines a method named **drawPictureOnPicture** that can be called to draw one picture onto another picture.
- Registers a **ChangeEvent** handler on the slider to:
 - Extract a percent-opacity value from the slider based on the position of the thumb.
 - Apply that opacity value to the butterfly image.
 - Draw the modified butterfly image on the beach image and display it.

Brief program specifications

Write a program named **Prob07** that uses the class definition for the class named **Prob07** in Listing 10 (p. 1780) along with Ericson's media library and the image files named Prob07a.jpg⁴¹⁸ and Prob07b.jpg⁴¹⁹ to produce the two output images shown in Figure 1 (p. 1768) .

Figure 1 - Screen output at startup.

Two output images

Note that Figure 1 (p. 1768) actually consists of two output images, one positioned below the other.

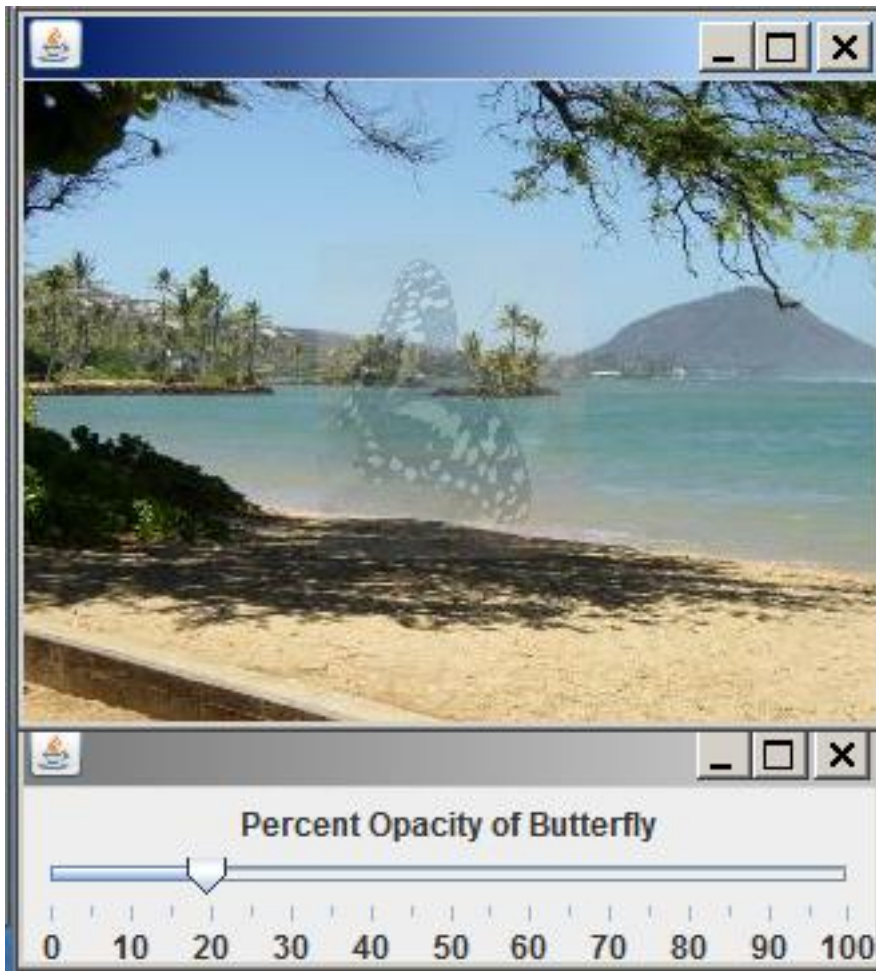

Move the thumb to the left

When you move the thumb on the slider to the left, the butterfly becomes less opaque (*more transparent*) as shown in Figure 2 (p. 1768) with total transparency at the extreme left end of the slider.

Figure 2 - Twenty-percent opacity.

⁴¹⁸<http://cnx.org/content/m44912/latest/Prob07a.jpg>

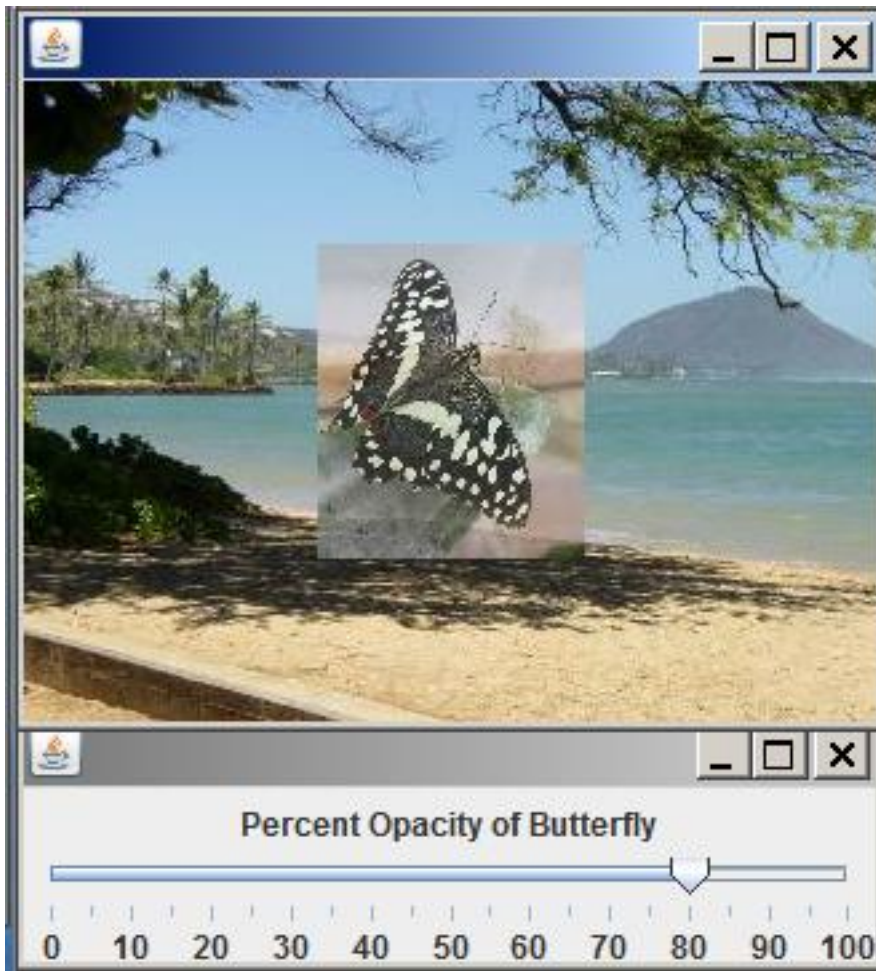

⁴¹⁹<http://cnx.org/content/m44912/latest/Prob07b.jpg>

Move the thumb to the right

When you move the thumb on the slider to the right, the butterfly becomes more opaque (*less transparent*) as shown in Figure 3 (p. 1769) with total opacity at the extreme right end of the slider.

Figure 3 - Eighty-percent opacity.

Define new classes

You may define new classes as necessary to cause your program to behave as required, but you may not modify the class definition for the class named **Prob07** given in Listing 10 (p. 1780) .

4.4.3.2.2.4 General background information

The image in a **SimplePicture** object is stored in an object of the **BufferedImage** class, which is a class in the standard Sun Java library.

Image data formats

An examination of the documentation for the **BufferedImage** class shows that the red, green, blue, and alpha values for each pixel can be formatted in about fourteen different ways in an object of the **BufferedImage** class.

No alpha data

Some of those formats, including the way that information is stored in a **SimplePicture** object, don't include an alpha value.

Modification of the SimplePicture class

One way to modify the **SimplePicture** class to force it to accommodate alpha transparency data is to modify one of the constructors for the **SimplePicture** class as shown in Listing 1 (p. 1772) . Note the change indicated by comments in Listing 1 . *(There are probably other ways that you can modify the class to achieve the same result as well.)*

Listing 1 - Modification of the SimplePicture class.

```

    /**
    * A constructor that takes the width and height desired
    * for a picture and creates a buffered image of that
    * size. This constructor doesn't show the picture.
    */
    public SimplePicture(int width, int height){
//Disable the following statement
//    bufferedImage = new BufferedImage(
//        width, height, BufferedImage.TYPE_INT_RGB);

//Modify constructor to support alpha transparency.
    bufferedImage = new BufferedImage(
        width, height, BufferedImage.TYPE_INT_ARGB);

    title = "None";
    fileName = "None";
    extension = ".jpg";
    setAllPixelsToAColor(Color.white);
} //end constructor

```

Table 4.273**Future Picture objects will accommodate alpha transparency**

Having made this modification, future objects instantiated from the **SimplePicture** class using this constructor will accommodate alpha transparency. (*The **SimplePicture** class is the superclass of the **Picture** class.*)

No complete listing of SimplePicture provided

Because of the simplicity of this modification, a complete listing of the modified **SimplePicture** class will not be provided in this module.

4.4.3.2.2.5 Discussion and sample code**4.4.3.2.2.5.1 The class named Prob07**

You can view the driver class named **Prob07** at the beginning of the source code in Listing 10 (p. 1780) . You are already familiar with the code in the **main** method of that class from earlier modules so I won't spend any time explaining it.

Briefly, the **main** method instantiates a new object of the class named **Prob07Runner** and calls the **run** method on that object. When the **run** method returns, the GUI shown in Figure 1 (p. 1768) has been displayed on the screen.

At that point, the program simply goes into an idle state and waits for the user to take some action that causes an event to be fired. When an event is fired, it is handled and the program goes idle again waiting for another event.

(Because there are images on the screen, the program does not actually terminate until the user forces it to terminate.)

4.4.3.2.2.5.2 The class named Prob07Runner

Will explain in fragments

I will explain this program in fragments. A complete listing of the program is provided in Listing 10 (p. 1780) near the end of the module.

Beginning of the class named Prob07Runner

The class named **Prob07Runner** begins in Listing 2 (p. 1773) .

Listing 2 - Beginning of the class named Prob07Runner.

```
class Prob07Runner extends JFrame{

private JPanel mainPanel = new JPanel();
private JPanel titlePanel = new JPanel();
private JSlider slider = new JSlider();

private Picture background = new Picture("Prob07b.jpg");
private Picture butterfly = new Picture("Prob07a.jpg");

private int backgroundWidth = background.getWidth();
private int backgroundHeight = background.getHeight();
private int butterflyWidth = butterfly.getWidth();
private int butterflyHeight = butterfly.getHeight();

private Picture display =
    new Picture(backgroundWidth,backgroundHeight);
private Picture tempPicture =
    new Picture(butterflyWidth,butterflyHeight);

private Image image = null;
private Graphics graphics = null;
```

Table 4.274

Class extends JFrame

Note that this class extends **JFrame** . An object of this class forms the lower part of the image shown in Figure 1 (p. 1768) that contains the slider.

The code in Listing 1 (p. 1772) is straightforward and shouldn't require an explanation.

When Listing 2 finishes executing...

When the code in Listing 2 (p. 1773) has finished executing, four new **Picture** objects have been instantiated and referred to by the following reference variables:

- **background** - The beach scene shown in the background in Figure 1 (p. 1768) .
- **butterfly** - Contains an opaque image of the butterfly shown in Figure 1 (p. 1768) .
- **display** - Empty picture the same size as the beach scene.
- **tempPicture** - Empty picture the same size as the butterfly.

In addition, a pair of working variables named **image** and **graphics** of the types **Image** and **Graphics** have been declared.

Finally, when the code in Listing 2 (p. 1773) has finished executing, two new **JPanel** objects and one new **JSlider** object have been instantiated and referred to by the variables named **mainPanel** , **titlePanel** , and **slider** .

Beginning of the constructor

The beginning of the constructor is shown in Listing 3 (p. 1774) .

Listing 3 - Beginning of the constructor.

```

    public Prob07Runner(){//constructor
//Do some initial setup.
setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);

slider.setMajorTickSpacing(10);
slider.setMinorTickSpacing(5);
slider.setPaintTicks(true);
slider.setPaintLabels(true);

mainPanel.setLayout(new BorderLayout());
titlePanel.add(new JLabel(
    "Percent Opacity of Butterfly"));
mainPanel.add(titlePanel,BorderLayout.NORTH);
mainPanel.add(slider,BorderLayout.CENTER);

getContentPane().add(mainPanel);

setSize(backgroundWidth + 7,97);
setLocation(0,backgroundHeight + 25);
setVisible(true);

```

Table 4.275

Although it may be necessary for you to go to Sun's Java documentation to learn about the detailed behavior of some of the methods that are called in Listing 3 (p. 1774) , the code in Listing 3 (p. 1774) is straightforward and should not require further explanation.

Display the initial background image

Listing 4 (p. 1774) displays the initial background image.

Instantiating and destroying a lot of new **Picture** objects as the user moves the slider to change the opacity would be very inefficient. To avoid this inefficiency, this program gets images from existing **Picture** objects and draws them on existing **Picture** objects without modifying the originals.

Listing 4 - Display the initial image.

```

graphics = display.getGraphics();
graphics.drawImage(background.getImage(),0,0,null);

```

Table 4.276

Display the butterfly at 50-percent opacity

Listing 5 (p. 1776) calls the **setOpacity** and **drawPictureOnPicture** methods to set the opacity of the butterfly and draw it onto the display with 50-percent opacity. The image of the butterfly is centered on the background.

Listing 5 - Display the butterfly at 50-percent opacity.

```

butterfly = setOpacity(butterfly,50);
drawPictureOnPicture(
    butterfly,
    display,
    backgroundWidth/2 - butterflyWidth/2,
    backgroundHeight/2 - butterflyHeight/2);
display.show();

```

Table 4.277**Put the constructor on hold**

At this point, I will put the discussion of the constructor on hold and explain the `setOpacity` and `drawPictureOnPicture` methods.

The setOpacity method

The `setOpacity` method is shown in its entirety in Listing 6 (p. 1776) .

Listing 6 - The setOpacity method.

```

private Picture setOpacity(
    Picture pic,double percentOpacity){

    int opacity = (int)(255*percentOpacity/100);
    int opacityMask = opacity << 24;

    for(int col = 0;col < butterflyWidth;col++){
        for(int row = 0;row < butterflyHeight;row++){
            //Get the pixel in basic int format.
            int basicPixel = pic.getBasicPixel(col,row);

            //Set the alpha value for the pixel.
            basicPixel = basicPixel & 0x00FFFFFF;
            basicPixel = basicPixel | opacityMask;

            //Set the modified pixel into tempPicture.
            tempPicture.setBasicPixel(col,row,basicPixel);
        }//end inner loop
    }//end outer loop

    return tempPicture;

} //end setOpacity

```

Table 4.278

This method copies an incoming picture into an existing temporary picture, setting the alpha value for every pixel to a specified value in the process. Then it returns the modified picture object's reference where it is saved in the reference variable named **butterfly** in Listing 5 (p. 1776) ,

A bitwise left-shift operation

The only thing in Listing 6 (p. 1776) that is new to this module is the use of a bitwise left-shift operation.

A 24-bit left shift

Listing 6 (p. 1776) converts the incoming **percentOpacity** value to an integer value ranging from 0 to 255. This value resides in the least significant eight bits of an **int** variable named **opacity** .

Then Listing 6 (p. 1776) applies the bitwise left-shift operator (*two left angle brackets*) to shift those eight bits into the eight most significant bits and stores the result in another **int** variable named **opacityMask** .

Apply the opacityMask to the pixels

A pair of nested **for** loops is used to set the alpha value of every pixel to the value of **opacityMask** using an overall bit-masking methodology that I explained in an earlier module.

The drawPictureOnPicture method

After the alpha value for every pixel in the butterfly image has been set to the specified opacity, Listing 5 (p. 1776) calls the method named **drawPictureOnPicture** to draw the modified butterfly image on the beach scene as shown in Figure 1 (p. 1768) .

The **drawPictureOnPicture** method is shown in its entirety in Listing 7 (p. 1777) .

Listing 7 - The drawPictureOnPicture method.

```
private void drawPictureOnPicture(
    Picture source,Picture dest,int xOff,
    int yOff){

    Graphics destGraphics = dest.getGraphics();
    Image sourceImage = source.getImage();
    destGraphics.drawImage(sourceImage,
        xOff,
        yOff,
        null);
} //end drawPictureOnPicture method
```

Table 4.279

This method draws the source picture onto the destination picture with an offset on both axes. There is nothing in Listing 7 (p. 1777) that I haven't explained in an earlier module.

Return to the explanation of the constructor

You are already familiar with the use of anonymous inner classes to create and register listener objects on Java source objects. The slider is a source object.

Listing 8 (p. 1778) begins the registration of an anonymous **ChangeEvent** listener on the slider.

Listing 8 - Begin the registration of an event handler on the slider.

```

    slider.addChangeListener(
new ChangeListener(){
    public void stateChanged(ChangeEvent e){
        //Draw a new copy of the background on the
        // display.
        graphics = display.getGraphics();
        graphics.drawImage(
            background.getImage(),0,0,null);
    }
});

```

Table 4.280

Restore the background image

Each time the slider fires a **ChangeEvent**, this event handler draws a new background image on the display. This erases what was previously drawn there, restoring a pristine image of the beach scene.

Draw a partially opaque butterfly image on the background

Then it uses the current value of the slider to set the opacity of the butterfly image and draws it centered on the display on top of the background image.

A series of events

The slider fires a series of **ChangeEvents** as the user moves the thumb on the slider. Listing 8 (p. 1778) begins the definition of the event handler method named **stateChanged**, which is registered on the slider. This method is called each time the slider fires a **ChangeEvent**.

Listing 8 (p. 1778) draws a new copy of the beach background image on the **Picture** object referred to by the reference variable named **background**. This image replaces the image that was previously drawn there.

Draw the butterfly and repaint

Listing 9 (p. 1779) calls the **setOpacity** and **drawPictureOnPicture** methods to:

- Set the opacity of the butterfly to the value currently represented by the position of the thumb on the slider. This is the value returned by the slider's **getValue** method.
- Draw the butterfly image on the background image.

Listing 9 - Draw the butterfly and repaint.

```

        //Set the opacity of butterfly and copy it onto
        // the display. Then repaint the display.
        butterfly =
            setOpacity(butterfly,slider.getValue());
        drawPictureOnPicture(
            butterfly,
            display,
            backgroundWidth/2 - butterflyWidth/2,
            backgroundHeight/2 - butterflyHeight/2);

        display.repaint();
    }//end stateChanged
} //end new ChangeListener
); //end addChangeListener
//-----//
} //end constructor

```

Table 4.281**Repaint the image**

Then Listing 9 (p. 1779) calls the **repaint** method to cause the modified image to be rendered onto the computer screen.

The end of the program

Listing 9 (p. 1779) also signals the end of the constructor, the end of the class named **Prob07Runner**, and the end of the program.

4.4.3.2.2.6 Run the program

I encourage you to copy the code from Listing 10 (p. 1780) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.3.2.2.7 Summary

In this module, you learned how to use a slider to continuously change the opacity of an image and draw that image onto a background image.

4.4.3.2.2.8 What's next?

In the next module, you will learn how to use a slider to continuously change the threshold detection level of an edge detector and to draw the edge-detected image on the screen.

4.4.3.2.2.9 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

4.4.3.2.3.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

The program described in this module requires the use of the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at *Java OOP: The Guzdial-Ericson Multimedia Class Library* ⁴²¹ .

4.4.3.2.3.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

4.4.3.2.3.2.1.1 Figures

- Figure 1 (p. 1784) . Contents of the file named Prob08.jpg.
- Figure 2 (p. 1785) . Output images.

4.4.3.2.3.2.1.2 Listings

- Listing 1 (p. 1788) . Beginning of the class named Prob08Runner.
- Listing 2 (p. 1789) . Beginning of the constructor.
- Listing 3 (p. 1789) . Beginning of the edgeDetector method.
- Listing 4 (p. 1791) . Detect using adjacent pixels in each column.
- Listing 5 (p. 1792) . Register a ChangeEvent listener on the slider.
- Listing 6 (p. 1793) . Complete program listing.

4.4.3.2.3.3 Preview

An earlier module (see *3D Displays, Color Distance, and Edge Detection* ⁴²²) explained how to implement an edge detection algorithm for a fixed detection threshold.

The primary objective of this module is to illustrate how to use a slider to continuously change the detection threshold of an edge detector and to draw the edge-detected image on the screen.

Brief program specifications

Write a program named **Prob08** that uses the class definition for the class named **Prob08** shown in Listing 6 (p. 1793) and Ericson's media library along with the image file named Prob08.jpg ⁴²³ (shown in Figure 1 (p. 1784)) to produce the two graphic output images shown in Figure 2 (p. 1785) .

Figure 1 - Contents of the file named Prob08.jpg.

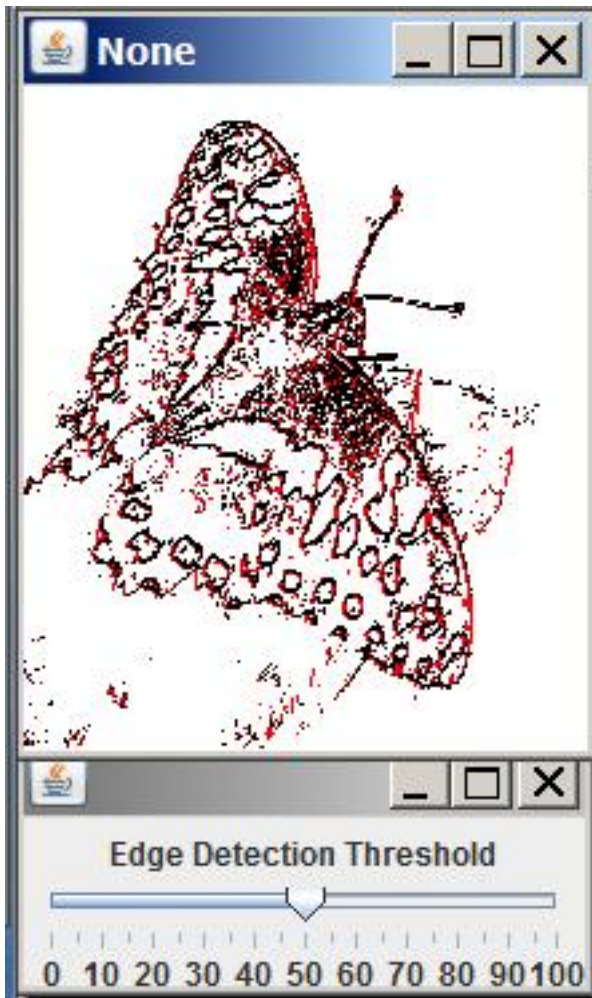

⁴²¹<http://cnx.org/content/m44148/latest/>

⁴²²<http://www.developer.com/java/other/article.php/3798646/3D-Displays-Color-Distance-and-Edge-Detection.htm>

⁴²³<http://cnx.org/content/m44913/latest/Prob08.jpg>

Figure 2 - Output images.

Note that Figure 2 (p. 1785) consists of two separate output images. The image containing the slider is positioned directly below the image of the butterfly.

New classes

You may define new classes as necessary to cause your program to behave as required, but you may not modify the class definition for the class named **Prob08** given in Listing 6 (p. 1793) .

The output images

The top image shown in Figure 2 (p. 1785) is an image of a butterfly to which an edge detection algorithm has been applied.

The bottom image in Figure 2 (p. 1785) is a slider that is used to control the edge-detection threshold.

Detect by rows and by columns

The edge-detection algorithm performs edge detection on a **Picture** object by rows and also by columns.

All edges that are detected by processing adjacent pixels on a row are marked in red. All edges that are detected by processing adjacent pixels on a column are marked in black.

If a pixel is determined to be on an edge using both approaches, it ends up being black. If an edge is not detected, the corresponding pixel is marked in white.

Program behavior

At startup, the thumb on the slider is positioned at the 50-percent mark and the image has been edge-detected using a threshold value of 50.

As you move the slider to the right, the threshold value increases up to a value of 100, which in turn causes the amount of white area in the image to increase.

As you move the slider to the left, the threshold value decreases down to a value of zero, which in turn causes the amount of white area in the image to decrease.

The program must terminate and return control to the operating system when you click the large X in the upper-right corner of the GUI containing the slider.

In addition to the output images described above, your program must display your name on the command-line screen.

4.4.3.2.3.4 Discussion and sample code

4.4.3.2.3.4.1 The class named Prob08

You can view the driver class named **Prob08** at the beginning of the source code in Listing 6 (p. 1793) . You are already familiar with the code in the **main** method of that class from earlier modules so I won't spend any time explaining it.

Brief description

Briefly, the **main** method instantiates a new object of the class named **Prob08Runner** and calls the **run** method on that object. When the **run** method returns, the GUI shown in Figure 2 (p. 1785) has been displayed on the screen.

At that point, the program simply goes into an idle state and waits for the user to take some action that causes an event to be fired. When an event is fired, it is handled and the program goes idle again waiting for another event.

(Because there are images on the screen, the program does not terminate until the user forces it to terminate.)

4.4.3.2.3.4.2 The class named Prob08Runner

Will explain in fragments

I will explain this program in fragments. A complete listing of the program is provided in Listing 6 (p. 1793) near the end of the module.

Beginning of the class named Prob08Runner

The class named **Prob08Runner** begins in Listing 1 (p. 1788) .

Listing 1 - Beginning of the class named Prob08Runner.

```
class Prob08Runner extends JFrame{

private JPanel mainPanel = new JPanel();
private JPanel titlePanel = new JPanel();
private JSlider slider = new JSlider();

private Picture butterfly =
        new Picture("Prob08.jpg");

private int butterflyWidth =
        butterfly.getWidth();
private int butterflyHeight =
        butterfly.getHeight();

private Picture display =
        new Picture(butterflyWidth,butterflyHeight);

private Pixel pix1;
private Pixel pix2;
private Pixel displayPixel;

private double distance = 0;
```

Table 4.282

There is nothing in Listing 1 (p. 1788) that I haven't explained in earlier modules, so I won't repeat those explanations here.

Beginning of the constructor

The constructor begins in Listing 2 (p. 1789) .

Listing 2 - Beginning of the constructor.

```

    public Prob08Runner(){//constructor
    setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);

    slider.setMajorTickSpacing(10);
    slider.setMinorTickSpacing(5);
    slider.setPaintTicks(true);
    slider.setPaintLabels(true);

    mainPanel.setLayout(new BorderLayout());
    titlePanel.add(new JLabel(
        "Edge Detection Threshold"));
    mainPanel.add(titlePanel,BorderLayout.NORTH);
    mainPanel.add(slider,BorderLayout.CENTER);

    getContentPane().add(mainPanel);

    setSize(butterflyWidth + 7,97);
    setLocation(0,butterflyHeight + 25);
    setVisible(true);

    //Produce the initial display with a threshold
    // value of 50, which matches the initial
    // position of the pointer on the slider.
    display = edgeDetector(butterfly,50);

    display.show();

```

Table 4.283**Put the constructor on hold**

The only thing that is new in Listing 2 (p. 1789) is the call to the method named `edgeDetector`. I will put the explanation of the constructor on hold while I explain the method named `edgeDetector`.

Beginning of the edgeDetector method

The `edgeDetector` method begins in Listing 3 (p. 1789).

This method performs edge detection on a **Picture** object by rows and also by columns.

As mentioned earlier, all edges that are detected by processing adjacent pixels on a row are marked in red.

All edges that are detected by processing adjacent pixels on a column are marked in black.

If a pixel is determined to be on an edge using both approaches, it ends up being black.

Listing 3 - Beginning of the edgeDetector method.*continued on next page*

```

private Picture edgeDetector(
    Picture picture,int threshold){
for(int row = 0;row < butterflyHeight - 1;row++){
  for(int col = 0;col < butterflyWidth - 1;col++){
    pix1 = picture.getPixel(col,row);
    displayPixel = display.getPixel(col,row);

    //First process two adjacent pixels on the
    // same row.
    pix2 = picture.getPixel(col + 1,row);

    //Get and save the color distance between the
    // two pixels.
    distance = pix1.colorDistance(pix2.getColor());

    //Compare the color distance to the threshold
    // and set the color of the pixel in the
    // display picture accordingly.
    if(distance > threshold){
      displayPixel.setColor(Color.RED);
    }else{
      displayPixel.setColor(Color.WHITE);
    }//end else
  }
}

```

Table 4.284

A pair of nested for loops

Listing 3 (p. 1789) shows the beginning of a pair of nested **for** loops that I used to detect the edges in the image of the butterfly. The code in Listing 3 (p. 1789) detects edges using adjacent pixels on each row and sets the color of the corresponding pixel in the output picture to red if an edge is detected.

(Note that the output picture referred to by **display** was instantiated as an instance variable in Listing 1 (p. 1788) .)

I explained an edge-detection algorithm in great detail in an earlier module titled 3D Displays, Color Distance, and Edge Detection ⁴²⁴ . The code in Listing 3 (p. 1789) is essentially an implementation of that algorithm where the detection threshold is an input parameter to the method.

Detect using adjacent pixels in each column

Listing 4 (p. 1791) detects edges using adjacent pixels on the columns.

⁴²⁴<http://www.developer.com/java/other/article.php/3798646/3D-Displays-Color-Distance-and-Edge-Detection.htm>

Listing 4 - Detect using adjacent pixels in each column.

```

        //Now process two adjacent pixels in the same
        // column using the same approach.
        pix2 = picture.getPixel(col,row + 1);
        distance = pix1.colorDistance(pix2.getColor());
        //Compare the color distance to the threshold
        // and change pixel color accordingly.
        if(distance > threshold){
            displayPixel.setColor(Color.BLACK);
        }//end if

        }//end inner loop
    }//end outer loop

    return display;
} //end edgeDetector

```

Table 4.285

If an edge is detected in Listing 4 (p. 1791) , the color of the corresponding pixel in the output picture is set to black.

Return the output picture and terminate

The `edgeDetector` method returns a reference to the output picture and terminates in Listing 4 (p. 1791) .

*(While writing this, I realized that because the variable named **display** is an instance variable, the program would also work properly if the `edgeDetector` method were to return void.)*

Returning to the constructor...

Returning to where we left off in Listing 2 (p. 1789) , the `show` method is called on the output picture referred to by `display` causing an image similar to that shown in Figure 2 (p. 1785) to be displayed.

Register a ChangeEvent listener on the slider

Listing 5 (p. 1792) registers an anonymous listener object on the slider. Each time the slider fires a `ChangeEvent` , the method named `stateChanged` is executed.

Listing 5 - Register a ChangeEvent listener on the slider.

```

        slider.addChangeListener(
        new ChangeListener(){
            public void stateChanged(ChangeEvent e){

                display = edgeDetector(
                    butterfly,slider.getValue());
                display.repaint();

                }//end stateChanged
            }//end new ChangeListener
        });//end addChangeListener
        //-----//
    }//end constructor
    //-----//
} //end class Prob08Runner

```

Table 4.286**Call the edgeDetector method**

The `stateChanged` method calls the `edgeDetector` method to get a new edge-detected image for which the threshold is the current value of the slider.

Then the display is repainted showing the new image on the screen.

The end of the program

Listing 5 (p. 1792) also signals the end of the constructor, the end of the class, and the end of the program.

4.4.3.2.3.5 Run the program

I encourage you to copy the code from Listing 6 (p. 1793) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.3.2.3.6 Summary

In this module, you learned how to use a slider to continuously change the threshold detection level of an edge detector and to draw the edge-detected image on the screen.

4.4.3.2.3.7 What's next?

In the next module, you will learn how to use a slider to continuously change the size of an image and to draw the scaled image onto a background image.

4.4.3.2.3.8 Miscellaneous

This section contains a variety of miscellaneous information.

4.4.3.2.4.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

The program described in this module requires the use of the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library⁴²⁶.

4.4.3.2.4.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

4.4.3.2.4.2.1.1 Figures

- Figure 1 (p. 1797) . Prob09a.jpg.
- Figure 2 (p. 1797) . Prob09b.jpg.
- Figure 3 (p. 1798) . Output images.

⁴²⁵This content is available online at <<http://cnx.org/content/m44914/1.7/>>.

⁴²⁶<http://cnx.org/content/m44148/latest/>

4.4.3.2.4.2.1.2 Listings

- Listing 1 (p. 1800) . Register a listener object on the slider.
- Listing 2 (p. 1801) . The method named drawScaledPictureOnPicture.
- Listing 3 (p. 1802) . Complete program listing.

4.4.3.2.4.3 Preview

The primary objective of this module is to illustrate how to use a slider to continuously change the size of an image and to draw the scaled image onto a background image.

Brief program specifications

Write a program named **Prob09** that uses the class definition for the class named **Prob09** shown in Listing 3 (p. 1802) and Ericson's media library along with the image files named Prob09a.jpg⁴²⁷ (see Figure 1 (p. 1797)) and Prob09b.jpg⁴²⁸ (see Figure 2 (p. 1797)) to produce the graphic output images shown in Figure 3 (p. 1798) .

Figure 1 - Prob09a.jpg.

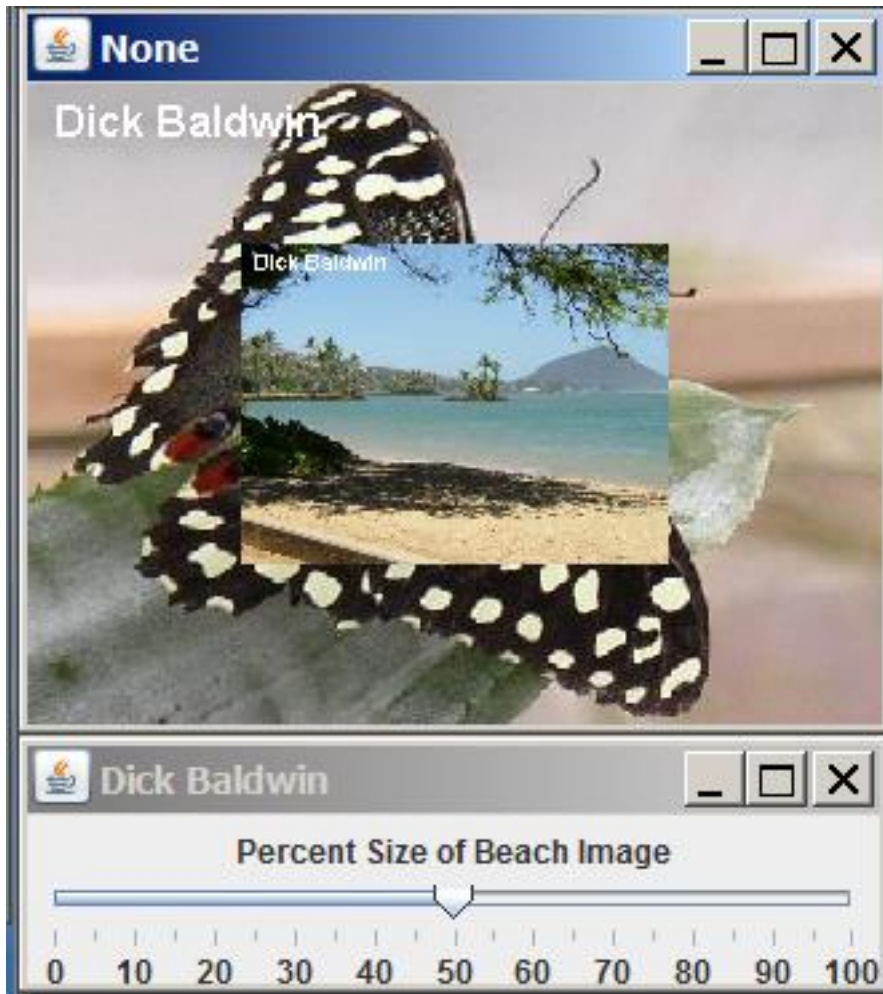

Figure 2 - Prob09b.jpg.

⁴²⁷<http://cnx.org/content/m44914/latest/Prob09a.jpg>

⁴²⁸<http://cnx.org/content/m44914/latest/Prob09b.jpg>

Figure 3 - Output images.

4.4.3.2.4.4 General background information

The overall structure of this program is very similar to a program that I explained in an earlier module titled *Controlling an Edge Detector with a Slider*⁴²⁹. The only significant difference between the two programs is the code that is executed when the slider fires a **ChangeEvent**.

I will explain the code that is new and different in this program and refer you back to the earlier module for an explanation of the remainder of the code. You can view the entire program in Listing 3 (p. 1802) near the end of the module.

4.4.3.2.4.5 Discussion and sample code

Register a listener object on the slider

The code in Listing 1 (p. 1800) registers an anonymous listener object on the slider.

⁴²⁹<http://cnx.org/content/m44913/latest>

Listing 1 - Register a listener object on the slider.

```

    slider.addChangeListener(
new ChangeListener(){
    public void stateChanged(ChangeEvent e){

        //Restore the background image of the butterfly.
        graphics = display.getGraphics();
        graphics.drawImage(
            butterfly.getImage(),0,0,null);

        drawScaledPictureOnPicture(beach,
                                   display,
                                   slider.getValue());

        display.repaint();
    }//end stateChanged
} //end new ChangeListener
); //end addChangeListener

```

Table 4.287

Each time the slider fires a **ChangeEvent** , the method named **stateChanged** is executed.

Behavior of the stateChanged method

The **stateChanged** method restores the background image of the butterfly. Then it calls the method named **drawScaledPictureOnPicture** to draw a scaled version of the beach on top of the background image using the slider value as the scale factor.

The slider value ranges from 0 to 100. This represents a scale factor as a percent of 1.0. In other words, the beach image is never scaled to a size that is larger than the size of the original beach image.

The image of the beach is always aligned with the center of the **contentPane** of the **JFrame** .

When the **drawScaledPictureOnPicture** method returns, the **repaint** method is called to cause the new image to be rendered on the computer screen.

The method named drawScaledPictureOnPicture

The method named **drawScaledPictureOnPicture** is shown in its entirety in Listing 2 (p. 1801) .

Listing 2 - The method named drawScaledPictureOnPicture.

```
private void drawScaledPictureOnPicture(
    Picture source,
    Picture dest,
    double scaleFactor){

    transform = new AffineTransform();

    double translateX = dest.getWidth()/2
        - source.getWidth()*scaleFactor/100/2;
    double translateY = dest.getHeight()/2
        - source.getHeight()*scaleFactor/100/2;;
    transform.translate(translateX,translateY);
    transform.scale(scaleFactor/100.0,scaleFactor/100.0);

    //Get the Graphics2D object used to draw on the
    // destination picture.
    g2 = (Graphics2D)dest.getGraphics();

    //Scale and draw the source image on the destination
    // image.
    g2.drawImage(source.getImage(),transform,null);

} //end drawScaledPictureOnPicture method
```

Table 4.288**Use an affine transform**

This method uses an affine transform to first translate and then scale the source picture and draws the scaled source picture onto the center of the destination picture.

I have published numerous tutorials that explain the use of Affine transforms in Java, including Applying Affine Transforms to Picture Objects ⁴³⁰. I won't repeat those explanations in this module, but will simply refer you to the earlier tutorials.

Keywords for a Google search

You can find my other tutorials that explain Affine transforms by using Google to search for the following keywords:

```
richard baldwin java affine transform
```

4.4.3.2.4.6 Run the program

I encourage you to copy the code from Listing 3 (p. 1802) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.3.2.4.7 Summary

In this module, you learned how to use a slider to continuously change the size of an image and to draw the scaled image onto a background image.

⁴³⁰<http://www.dickbaldwin.com/java/Java358.htm>

4.4.3.2.4.8 What's next?

In the next module, you will learn how to use a JSlider object along with Affine Transforms to control the rotation of an image.

4.4.3.2.4.9 Miscellaneous

This section contains a variety of miscellaneous information.

// handler restores the background image of the
// butterfly. Then it draws a scaled version of the
// beach on top of the background image using the
// slider value, which ranges from 0 to 100 as the
// scale factor as a percent of 1.0. The image of the
// beach is always aligned with the center
// of the contentPane of the JFrame.
slider.addChangeListener(
    new ChangeListener(){
        public void stateChanged(ChangeEvent e){

            //Restore the background image of the butterfly.
            graphics = display.getGraphics();
            graphics.drawImage(
                butterfly.getImage(), 0, 0, null);

            drawScaledPictureOnPicture(beach,
                display,
                slider.getValue());

            display.repaint();
        } //end stateChanged
    } //end new ChangeListener
); //end addChangeListener
//-----//
} //end constructor
//-----//

//Scales and draws the source picture onto the center
// of the destination picture.
private void drawScaledPictureOnPicture(
    Picture source,

```

```

        Picture dest,
        double scaleFactor){

    transform = new AffineTransform();

    double translateX = dest.getWidth()/2
        - source.getWidth()*scaleFactor/100/2;
    double translateY = dest.getHeight()/2
        - source.getHeight()*scaleFactor/100/2;;
    transform.translate(translateX,translateY);
    transform.scale(scaleFactor/100.0,scaleFactor/100.0);

    //Get the Graphics2D object used to draw on the
    // destination picture.
    g2 = (Graphics2D)dest.getGraphics();

    //Scale and draw the source image on the destination
    // image.
    g2.drawImage(source.getImage(),transform,null);

} //end drawScaledPictureOnPicture method
} //end class Prob09Runner

-end-

```

4.4.3.2.5 Java3120 Java OOP Controlling Image Rotation with a Slider and Affine Transforms⁴³¹

4.4.3.2.5.1 Table of Contents

4.4.3.2.5.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

The program described in this module requires the use of the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library⁴³².

⁴³¹This content is available online at <<http://cnx.org/content/m44915/1.7/>>.

⁴³²<http://cnx.org/content/m44148/latest/>

4.4.3.2.5.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

4.4.3.2.5.2.1.1 Figures

- Figure 1 (p. 1806) . Program output at startup.
- Figure 2 (p. 1808) . Program output for slider at zero.
- Figure 3 (p. 1809) . Program output for slider at 240.

4.4.3.2.5.2.1.2 Listings

- Listing 1 (p. 1811) . Beginning of the class named Prob10Runner.
- Listing 2 (p. 1812) . Beginning of the constructor for the Prob10Runner class.
- Listing 3 (p. 1813) . Construct the GUI for the slider.
- Listing 4 (p. 1813) . Rotate and display the butterfly.
- Listing 5 (p. 1814) . Register a `ChangeListener` on the slider.
- Listing 6 (p. 1815) . Beginning of the `rotatePicture` method.
- Listing 7 (p. 1815) . Set up the translation transform.
- Listing 8 (p. 1816) . Concatenate the transforms.
- Listing 9 (p. 1816) . Transform and draw the butterfly image.
- Listing 10 (p. 1817) . Complete program listing.

4.4.3.2.5.3 Preview

In this lecture, I will explain a program that uses **Affine Transforms** to rotate an image by a specified angle around a specified anchor point.

Then the program translates the image so as to center it in a **JFrame** object.

Specification of the rotation angle

A **JSlider** is used to specify the rotation angle.

The range of the slider is from 0 to 360 degrees.

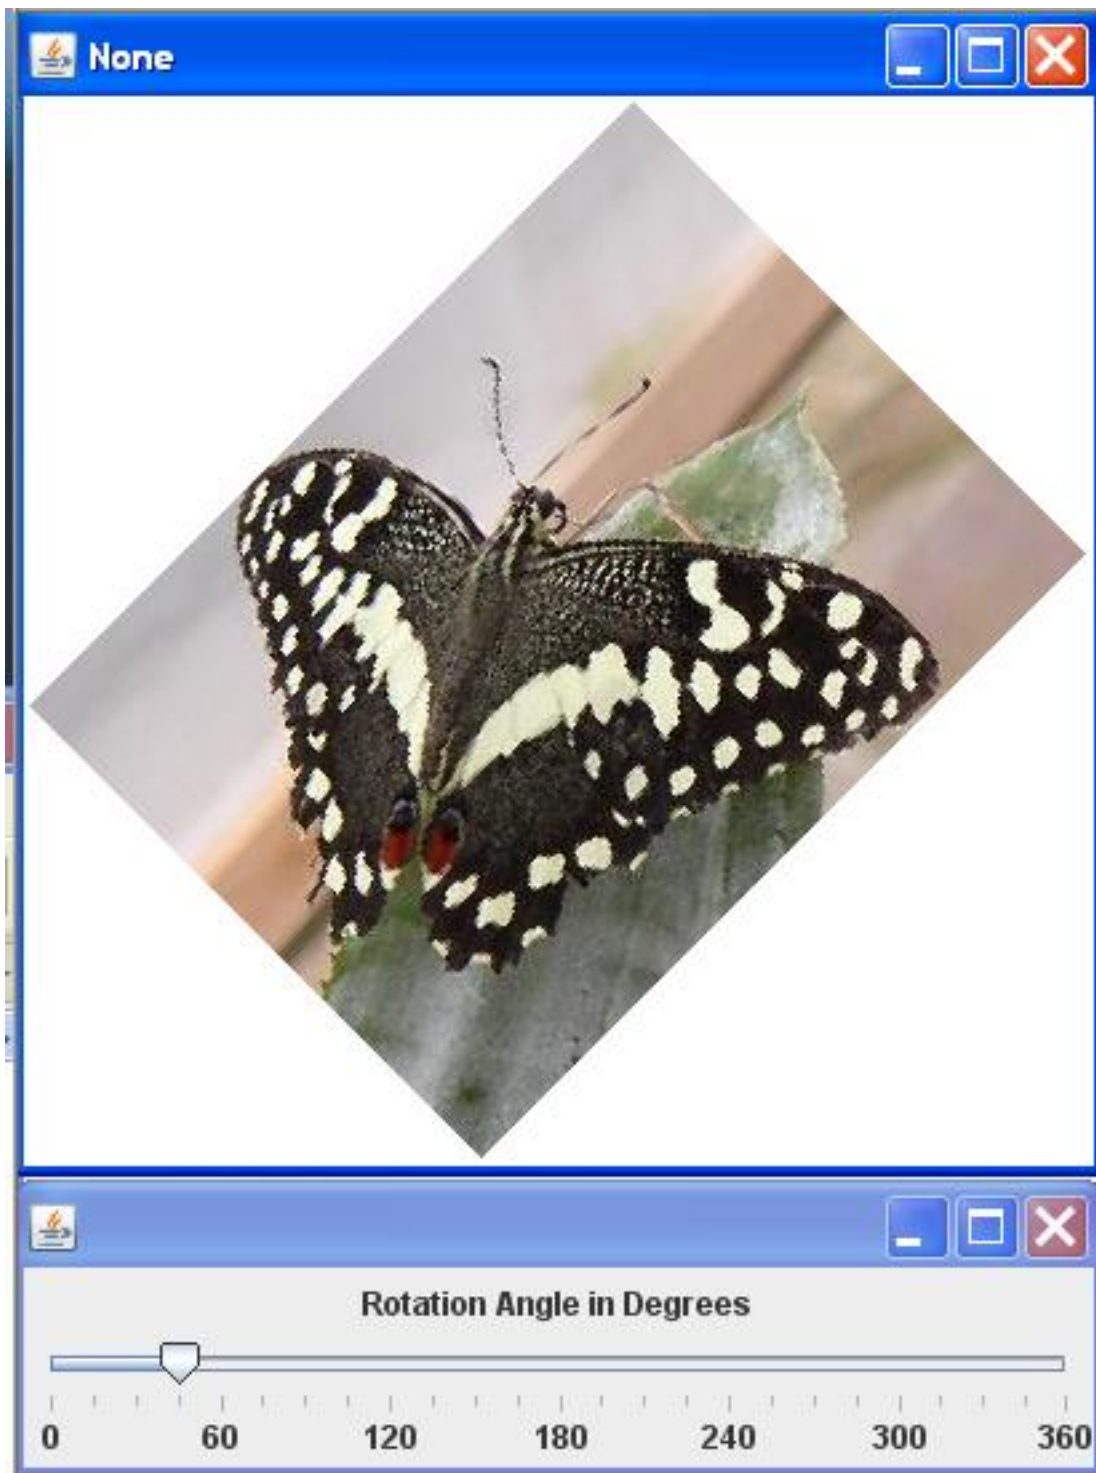

The position of the thumb on the slider specifies a counter-clockwise rotation angle in degrees.

Program output at startup

The thumb on the slider is at 45 degrees when the program starts running.

This causes the initial rotation angle of the butterfly image to be 45 degrees counter-clockwise as shown in Figure 1 (p. 1806) .

Figure 1 - Program output at startup.

Corners barely graze inner-edges of the frame's borders

Note that for the initial rotation angle shown in Figure 1 (p. 1806) , the corners of the image almost touch the inner-edges of the borders on the frame.

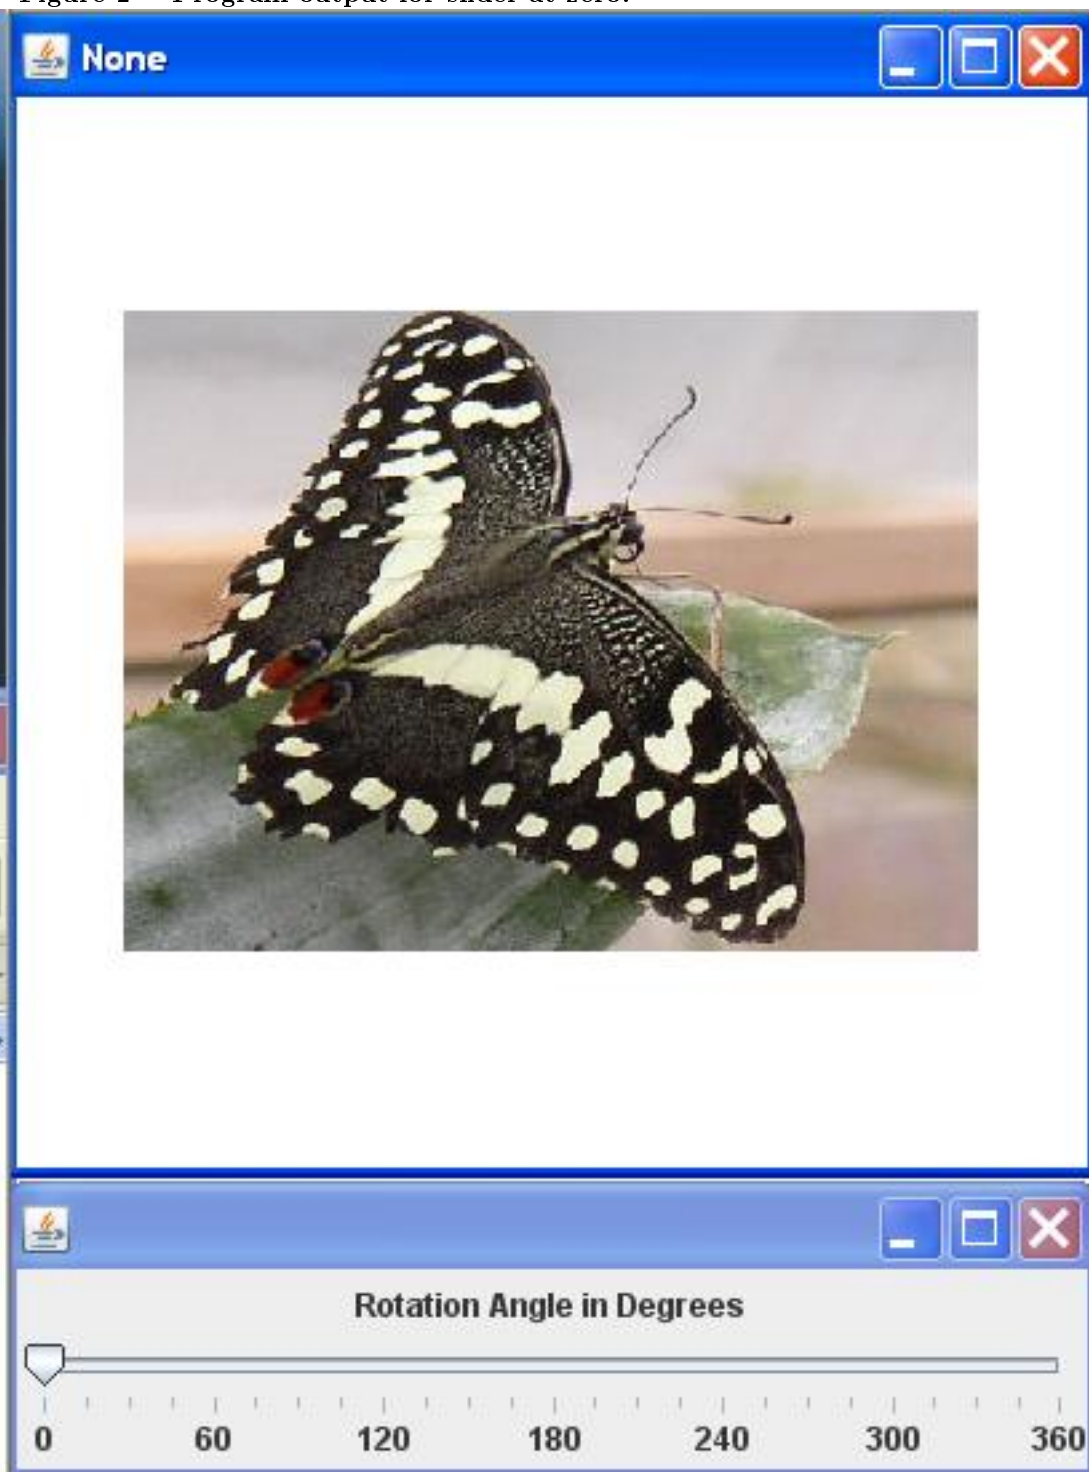

If you run the program and rotate the image, you will see that the size of the frame is such that the corners of the image barely graze the inner-edges for those cases where the diagonals of the image are horizontal and

vertical.

Program output for slider at zero degrees

Figure 2 (p. 1808) shows the program output when the thumb on the slider has been moved to zero degrees at the far-left end of the slider.

Figure 2 - Program output for slider at zero.

Program output for slider at 240 degrees

Figure 3 (p. 1809) shows the result of positioning the thumb on the slider at 240 degrees.

Figure 3 - Program output for slider at 240.

**Brief program specifications**

Write a program named **Prob10** that uses the **Prob10** class definition shown in Listing 10 (p. 1817)

and Ericson's media library along with the image file named Prob10.jpg⁴³³ to produce the graphic output images shown in Figure 1 (p. 1806) through Figure 3 (p. 1809) .

The butterfly image rotates smoothly around its center as you move the slider back and forth.

The program must terminate and return control to the operating system when you click the large X in the upper-right corner of the GUI containing the slider.

General background information

The overall structure of this program is very similar to programs that I explained in earlier lectures titled

- Controlling an Edge Detector with a Slider⁴³⁴ , and
- Controlling an Image-Scaling Program with a Slider⁴³⁵ .

The most significant difference...

Is the code that is executed when the slider fires a **ChangeEvent** . There are a few other differences as well.

New and different code

I will explain the code that is new and different in this program.

I will refer you back to the earlier lectures for an explanation of the remainder of the code.

You can view the entire program in Listing 10 (p. 1817) .

4.4.3.2.5.4 Discussion and sample code

Beginning of the class named Prob10Runner

The code in the **main** method in Listing 10 (p. 1817) instantiates a new object of the class named **Prob10Runner** .

Listing 1 (p. 1811) shows the beginning of the class named **Prob10Runner** .

Listing 1 (p. 1811) declares several instance variables and initializes some of them.

I will refer back to some of these variables in later paragraphs.

⁴³³<http://cnx.org/content/m44915/latest/Prob10.jpg>

⁴³⁴<http://cnx.org/content/m44913/latest>

⁴³⁵<http://cnx.org/content/m44914/latest>

Listing 1 - Beginning of the class named Prob10Runner.

```
class Prob10Runner extends JFrame{

private JPanel mainPanel = new JPanel();
private JPanel titlePanel = new JPanel();

//Instantiate a new slider setting the limits and the
// initial position of the thumb.
private JSlider slider = new JSlider(0,360,45);

private Picture butterfly = new Picture("Prob10.jpg");
private Picture background = null;

private int butterflyWidth = butterfly.getWidth();
private int butterflyHeight = butterfly.getHeight();

private Picture display = null;
private int displayWidth = 0;
private int displayHeight = 0;

private Image image = null;
private Graphics graphics = null;
private AffineTransform rotateTransform = null;
private AffineTransform translateTransform = null;
private Graphics2D g2 = null;
```

Table 4.289**Beginning of the constructor for the Prob10Runner class**

Listing 2 (p. 1812) shows the beginning of the constructor for the class named **Prob10Runner** .

Listing 2 - Beginning of the constructor for the Prob10Runner class.

```

    public Prob10Runner(){//constructor

    setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);

    //Compute the minimum dimensions allowed for the
    // display window that will contain the butterfly
    // image rotated at any angle. This turns out to
    // be a square with the length of each side equal
    // to the diagonal length of the butterfly picture.
    //The length of each side was increased by one
    // pixel to guard against loss of precision when
    // converting from double to int.
    int diagonal = 1 + (int)(Math.sqrt(
        butterflyWidth*butterflyWidth +
        butterflyHeight*butterflyHeight));

    //Instantiate the picture in which the rotated
    // butterfly image will be displayed.
    display = new Picture(diagonal,diagonal);
    displayWidth = displayHeight = diagonal;

    //This picture provides a white background the same
    // size as the display picture.
    background = new Picture(diagonal,diagonal);

```

Table 4.290**Not much that is new here**

The only thing that might be considered new in Listing 2 (p. 1811) is the code that computes the minimum dimensions for a display window that will contain the butterfly image rotated by any angle.

The rationale for this computation is explained in the comments.

Construct the GUI for the slider

The code in Listing 3 (p. 1813) constructs the GUI that contains the slider shown in Figure 1 (p. 1806) . Although the code in Listing 3 (p. 1813) is a little tedious, there are no new concepts associated with that code.

Listing 3 - Construct the GUI for the slider.

```

        //Construct the GUI for the slider.
slider.setMajorTickSpacing(60);
slider.setMinorTickSpacing(15);
slider.setPaintTicks(true);
slider.setPaintLabels(true);

mainPanel.setLayout(new BorderLayout());
titlePanel.add(new JLabel(
        "Rotation Angle in Degrees"));
mainPanel.add(titlePanel,BorderLayout.NORTH);
mainPanel.add(slider,BorderLayout.CENTER);

getContentPane().add(mainPanel);
pack();//Adjust the size of the slider GUI.

//Compute an improved size and location for the
// GUI containing the slider.
setSize(displayWidth + 2 * getInsets().left,
        mainPanel.getHeight() + slider.getHeight());
setLocation(0,displayHeight + getInsets().top
        + getInsets().bottom + 1);
setVisible(true);

```

Table 4.291**Rotate and display the butterfly**

The code in Listing 4 (p. 1813) calls the method named **rotatePicture** , passing the initial value of the thumb on the slider as a parameter to cause the initial display of the butterfly to be properly rotated.

Then Listing 4 (p. 1813) calls the **show** method on the display to cause the rotated butterfly image to be displayed as shown in Figure 1 (p. 1806) .

Listing 4 - Rotate and display the butterfly.

```

        rotatePicture(slider.getValue());

display.show();

```

Table 4.292**Register a ChangeListener on the slider**

The code in Listing 5 (p. 1814) registers an anonymous **ChangeListener** object on the slider.

Listing 5 - Register a ChangeListener on the slider.

```

        slider.addChangeListener(
new ChangeListener(){
    public void stateChanged(ChangeEvent e){
        //Restore the background image of the display
        // to all white.
        graphics = display.getGraphics();
        graphics.drawImage(
            background.getImage(),0,0,null);

        //Rotate the butterfly image, draw it on the
        // display, and repaint the display on the
        // screen..
        rotatePicture(slider.getValue());
        display.repaint();
    }//end stateChanged
} //end new ChangeListener
); //end addChangeListener
//-----//
} //end constructor

```

Table 4.293

Each time the slider fires a **ChangeEvent** , the **stateChanged** method in Listing 5 (p. 1814) is executed.

The **stateChanged** method begins by restoring the background image of the display.

Then the **stateChanged** method calls the **rotatePicture** method to draw a rotated version of the butterfly on top of the background image using the slider value, (*which ranges from 0 to +360*) , as the rotation angle in degrees.

The image of the butterfly (see *Figure 1* (p. 1806)) is always centered in the display picture.

Finally, the **stateChanged** method causes the display to be repainted to force the rotated image to appear on the screen.

End of the constructor

Listing 5 (p. 1814) signals the end of the constructor for the class named **Prob10Runner** .

Beginning of the rotatePicture method

The **rotatePicture** method begins in Listing 6 (p. 1815) .

Listing 6 - Beginning of the rotatePicture method.

```

private void rotatePicture(double angle){

//Set up the rotation transform
rotateTransform = new AffineTransform();
//Negate the angle for counter-clockwise rotation.
rotateTransform.rotate(-Math.toRadians(angle),
                      butterflyWidth/2,
                      butterflyHeight/2);

```

Table 4.294

The **rotatePicture** method accepts a rotation angle in degrees as an incoming parameter. The **rotatePicture** method

- rotates a butterfly image by that angle around its center,
- translates the rotated image, and
- draws the rotated image in the center of a display picture.

Set up the rotation transform

Listing 6 (p. 1815) begins by instantiating a new object of the **AffineTransform** class.

Then it calls the **rotate** method on the transform object to configure that object for use in rotating the image of the butterfly.

Overloaded versions of the rotate method

There are several overloaded versions of the **rotate** method.

The version called in Listing 6 (p. 1815) requires three parameters:

- The rotation angle in radians
- The X coordinate of the anchor point (*point around which the rotation will take place*) .
- The Y coordinate of the anchor point.

A positive rotation value indicates a clockwise rotation.

Convert from degrees to radians

Listing 6 (p. 1815) converts the incoming angle in degrees to radians

The code in Listing 6 (p. 1815) applies a minus sign to convert the angle from a positive value to a negative value for **counter-clockwise** rotation, and passes that value as the rotation parameter.

Specify the rotation anchor point

Listing 6 (p. 1815) also specifies the center of the butterfly image as the anchor point.

Set up the translation transform

Listing 7 (p. 1815) sets up the translation transform that will be used to translate the rotated image to the center of the new **Picture** object.

Listing 7 - Set up the translation transform.

continued on next page

```

    translateTransform = new AffineTransform();
    translateTransform.translate(
        (displayWidth - butterflyWidth)/2,
        (displayHeight - butterflyHeight)/2);

```

Table 4.295

Listing 7 (p. 1815) instantiates a new **AffineTransform** object.

Then it calls the **translate** method to configure that object for use in translating (*moving*) the rotated image of the butterfly.

The translation transform object will be concatenated with the rotation object from Listing 6 (p. 1815) to produce an **AffineTransform** object that can **rotate** and **translate**, in that order.

Concatenate the transforms

Listing 8 (p. 1816) concatenates the **AffineTransform** object referred to by **translateTransform** with the transform object referred to by **rotateTransform**.

Listing 8 - Concatenate the transforms.

```

    translateTransform.concatenate(rotateTransform);

```

Table 4.296

The resulting composite transform

The concatenation in Listing 8 (p. 1816) results in an **Affine Transform** object referred to by **translateTransform** that will first rotate the image around its center and then translate the rotated image to the center of the new **Picture** object.

The order of operations is very important

When rotating and translating images, it is important that the two operations be performed in the correct order.

Otherwise, the results might not be what you want.

Transform and draw the butterfly

Listing 9 (p. 1816) applies the composite transform to the butterfly image and draws the transformed image on the output picture as shown in Figure 1 (p. 1806), Figure 2 (p. 1808), and Figure 3 (p. 1809).

Listing 9 - Transform and draw the butterfly image.

```

    Graphics2D g2 = (Graphics2D)display.getGraphics();
    g2.drawImage(butterfly.getImage(),
        translateTransform,
        null);

    }//end rotatePicture

} //end class Prob10Runner

```

Table 4.297

The end of the program

Listing 9 (p. 1816) also signals the end of the `rotatePicture` method, the end of the `Prob10Runner` class, and the end of the program.

4.4.3.2.5.5 Run the program

I encourage you to copy the code from Listing 10 (p. 1817) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.3.2.5.6 Summary

In this lecture, you learned how to use a `JSlider` object along with `Affine Transforms` to control the rotation of an image.

4.4.3.2.5.7 What's next?

In the next module, you will learn how to open an image file (*specified by a string in a text field*) in a `PictureExplorer` object.

4.4.3.2.5.8 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java OOP: Controlling Image Rotation with a Slider and Affine Transforms

4.4.3.3.1.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

⁴³⁶This content is available online at <http://cnx.org/content/m44916/1.7/>.

The program described in this module requires the use of the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library ⁴³⁷ .

4.4.3.3.1.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

4.4.3.3.1.2.1.1 Figures

- Figure 1 (p. 1822) . Program output at startup.
- Figure 2 (p. 1822) . Screen shot after the image is loaded.

4.4.3.3.1.2.1.2 Listings

- Listing 1 (p. 1823) . Complete program listing.
- Listing 2 (p. 1825) . The driver class.
- Listing 3 (p. 1826) . Beginning of the Prob11Runner class.
- Listing 4 (p. 1827) . Beginning of the constructor.
- Listing 5 (p. 1827) . Beginning of anonymous listener class.
- Listing 6 (p. 1828) . Completion of the anonymous listener class.

4.4.3.3.1.3 Preview

This program demonstrates how to specify an image file in a text field, and open the image in a new **PictureExplorer** object.

Program output at startup

Figure 1 (p. 1822) shows the program output at startup.

Figure 1 - Program output at startup.

Pre-loaded image file name

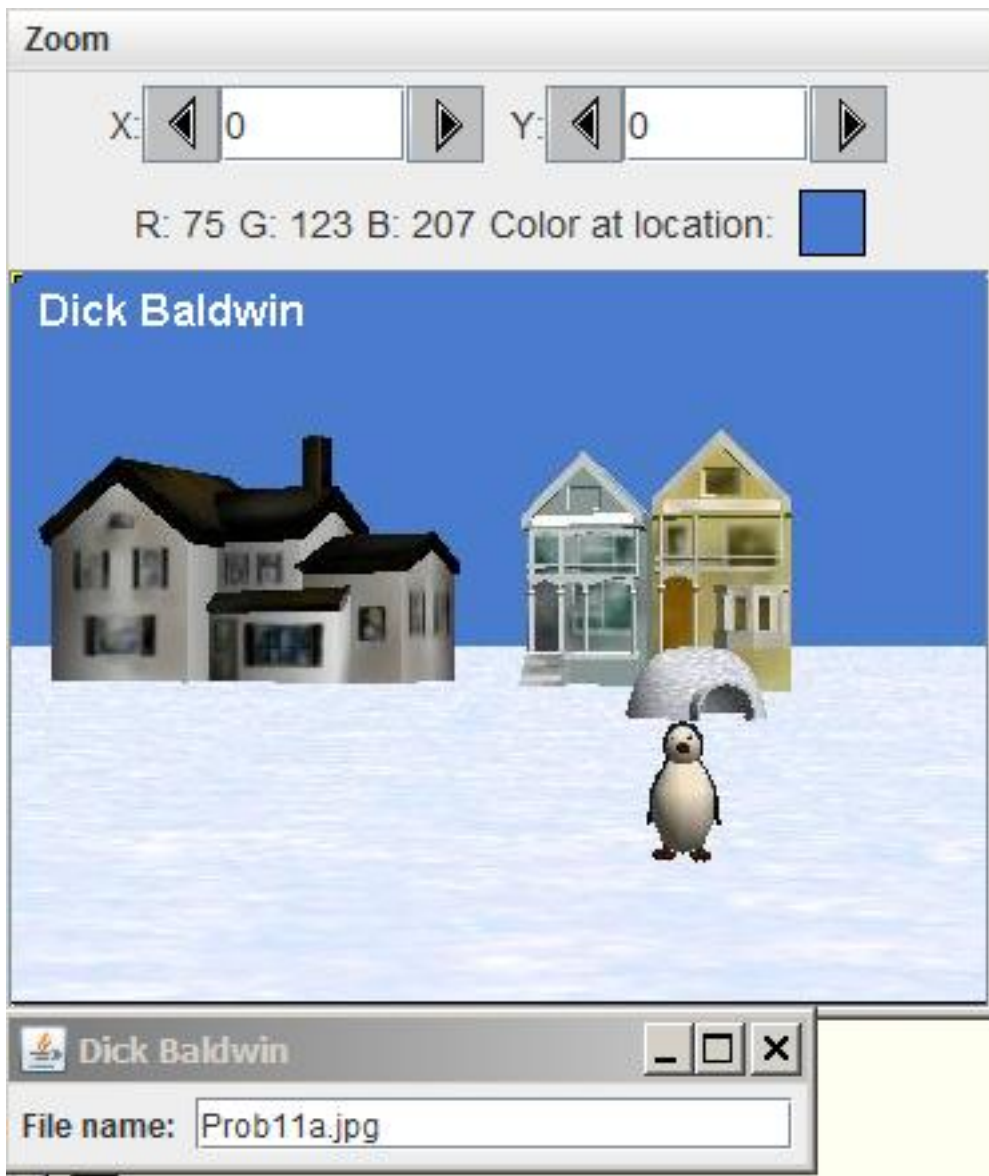

For convenience, the text field is pre-loaded with the name of an image file that is located in the current directory.

Press Enter to load the image

Pressing the Enter key while the text field has the focus will cause the image to be loaded into a **PictureExplorer** object, and will cause the **PictureExplorer** object to be displayed as shown in Figure 2 (p. 1822) .

Figure 2 - Screen shot after the image is loaded.

⁴³⁷<http://cnx.org/content/m44148/latest/>

Control panel is relocated

Note in Figure 2 (p. 1822) that the control panel containing the text field has been automatically relocated to a position immediately below the **PictureExplorer** object.

Another image file in the current directory

Entering the path and name of any jpeg file will cause that file to be loaded into a new **PictureExplorer** object.

4.4.3.3.1.4 Complete program listing

A complete listing of the program discussed in this lecture is shown in Listing 1 (p. 1823) below.

Listing 1 - Complete program listing.

```
/*File Prob11 Copyright 2012 R.G.Baldwin
The purpose of this program is to demonstrate the use of
a JTextField object to specify the name of an image file,
```

which is then loaded and displayed in a `PictureExplorer` object.

The text field is pre-loaded with the name of an image file that is in the current directory (`Prob11a.jpg`).

An image file named `Prob11b.jpg` is also in the current directory and can be loaded and displayed by entering the name in the text field.

Any image file on the disk can be loaded and displayed by entering the path and name of the image file.

```

import javax.swing.JFrame;
import javax.swing.JPanel;
import javax.swing.JTextField;
import javax.swing.JLabel;
import java.awt.event.ActionEvent;
import java.awt.event.ActionListener;
import javax.swing.WindowConstants;

public class Prob11{
    public static void main(String[] args){
        new Prob11Runner();
    }//end main method
} //end class Prob11
//=====//

class Prob11Runner extends JFrame{
    private Prob11Runner jFrameObj = null;
    private PictureExplorer explorer = null;
    private Picture pix;

    private JPanel fileNamePanel = new JPanel();
    private JTextField inputFileNameField =
        new JTextField("Prob11a.jpg",20);

    private String fileName = "no file specified";
    //-----//

    public Prob11Runner(){//constructor
        fileNamePanel.add(new JLabel("File name: "));
        fileNamePanel.add(inputFileNameField);

        //Add the fileNamePanel to the content pane, adjust
        // to the correct size, and set the title.
        getContentPane().add(fileNamePanel);
        pack();
        setTitle("Dick Baldwin");
    }
}

```

```

//Make the GUI visible, set the focus, and establish
// a reference to the GUI object.
setVisible(true);
inputFileNameField.requestFocus();
jFrameObj = this;

//-----//
//Register listeners on the user input field.
//-----//

inputFileNameField.addActionListener(
    new ActionListener(){
        public void actionPerformed(ActionEvent e){
            fileName = inputFileNameField.getText();

            pix = new Picture(fileName);
            pix.addMessage("Dick Baldwin",10,20);
            explorer = new PictureExplorer(pix);

            //Set the location for the control GUI
            // immediately below the PictureExplorer object,
            // and set its default close operation.
            setLocation(0,pix.getHeight() + 128);
            jFrameObj.setDefaultCloseOperation(
                WindowConstants.EXIT_ON_CLOSE);
        }//end actionPerformed
    }//end newActionListener
);//end addActionListener
//-----//
}//end constructor
//-----//
}//end class Prob11Runner

```

4.4.3.3.1.5 Will explain the code in fragments

As usual, I will break the code down, and explain it in fragments.

The driver class

The driver class is shown in Listing 2 (p. 1825) .

There is nothing new in Listing 2 (p. 1825) .

Listing 2 - The driver class.

```

public class Prob11{
    public static void main(String[] args){
        new Prob11Runner();
    }//end main method
}//end class Prob11

```

Table 4.298

Beginning of the Prob11Runner class

The **Prob11Runner** class begins in Listing 3 (p. 1826) .

Listing 3 (p. 1826) declares several instance variables that will be used later in the program, initializing some of them.

Note that the class extends **JFrame** , so an object of the class "is a" **JFrame** object.

Listing 3 - Beginning of the Prob11Runner class.

```
class Prob11Runner extends JFrame{
private Prob11Runner jFrameObj = null;
private PictureExplorer explorer = null;
private Picture pix;

private JPanel fileNamePanel = new JPanel();
private JTextField inputFileNameField =
    new JTextField("Prob11a.jpg",20);

private String fileName = "no file specified";
```

Table 4.299**Beginning of the constructor**

The constructor for the **Prob11Runner** class begins in Listing 4 (p. 1827) .

The code in Listing 4 (p. 1827) performs the physical construction of the GUI show in Figure 1 (p. 1822)

The code in Listing 4 (p. 1827) saves a reference to the object so that it can be accessed later from within a listener object.

Listing 4 - Beginning of the constructor.

```

    public Prob11Runner(){//constructor
    fileNamePanel.add(new JLabel("File name: "));
    fileNamePanel.add(inputFileNameField);

    //Add the fileNamePanel to the content pane, adjust
    // to the correct size, and set the title.
    getContentPane().add(fileNamePanel);
    pack();
    setTitle("Dick Baldwin");

    //Make the GUI visible, set the focus, and establish
    // a reference to the GUI object.
    setVisible(true);
    inputFileNameField.requestFocus();
    JFrameObj = this;

```

Table 4.300**Register a listener on the text field**

Listing 5 (p. 1827) shows the beginning of code that instantiates an **ActionListener** object of an anonymous listener class, and registers the listener object on the text field shown in Figure 1 (p. 1822) .

Listing 5 - Beginning of anonymous listener class.

```

    inputFileNameField.addActionListener(
    new ActionListener(){
    public void actionPerformed(ActionEvent e){
        fileName = inputFileNameField.getText();

        pix = new Picture(fileName);
        pix.addMessage("Dick Baldwin",10,20);

        explorer = new PictureExplorer(pix);

```

Table 4.301**Get image and create Picture object**

Listing 5 (p. 1827) begins by getting the name of the image file from the text field, using that image file to create a new **Picture** object, and adding a name in the upper-left corner of the picture.

Create new PictureExplorer object

Then Listing 5 (p. 1827) instantiates a new **PictureExplorer** object that encapsulates the **Picture** object that was created from the image file.

Completion of the anonymous listener class

Listing 6 (p. 1828) shows the completion of the anonymous listener class, as well as the end of the constructor, and the end of the class named **Prob11Runner** .

Listing 6 - Completion of the anonymous listener class.

```

        setLocation(0,pix.getHeight() + 128);

        JFrameObj.setDefaultCloseOperation(
            WindowConstants.EXIT_ON_CLOSE);
    }//end action performed
    }//end newActionListener
);//end addActionListener
//-----//
}//end constructor
//-----//
}//end class Prob11Runner

```

Table 4.302

Relocate the GUI

Listing 6 (p. 1828) begins by setting the location of the GUI to a location that is immediately below the **PictureExplorer** object.

Relocate the GUI (cont'd)

Note that the value of 128 pixels was experimentally determined to be the approximate difference between the height of the **PictureExplorer** object and the height of the **Picture** object that it encapsulates.

(This difference may not be correct for different display options on different operating systems.)

Set the default close operation

Listing 6 (p. 1828) ends by setting the behavior of the X-button in the GUI to a value that will cause it to terminate the program when the button is clicked.

4.4.3.3.1.6 Run the program

I encourage you to copy the code from Listing 1 (p. 1823) and download the image file named Prob11a.jpg⁴³⁸ . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.3.3.1.7 What's next?

In the next module, you will learn how to extract color data from a selected pixel in a **PictureExplorer** object, and how to display a color value in a text field. You will also learn how to disable the X-button in the **PictureExplorer** object, and how to use a reference to the **JFrame** object that serves as a container for the **PictureExplorer** object.

4.4.3.3.1.8 Miscellaneous

This section contains a variety of miscellaneous information.

4.4.3.3.2.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

The program described in this module requires the use of the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library⁴⁴⁰.

⁴³⁹This content is available online at <<http://cnx.org/content/m44917/1.6/>>.

⁴⁴⁰<http://cnx.org/content/m44148/latest/>

4.4.3.3.2.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

4.4.3.3.2.2.1.1 Figures

- Figure 1 (p. 1830) . Program output at startup.
- Figure 2 (p. 1831) . Program output after clicking the button.

4.4.3.3.2.2.1.2 Listings

- Listing 1 (p. 1833) . Addition of getter methods.
- Listing 2 (p. 1834) . Disabled the call to `setDefaultCloseOperation` method.
- Listing 3 (p. 1834) . The driver class for Prob12.
- Listing 4 (p. 1834) . Beginning of the class named Prob12Runner.
- Listing 5 (p. 1835) . Beginning of the constructor.
- Listing 6 (p. 1835) . Construct a `Picture` object.
- Listing 7 (p. 1836) . Construct a `PictureExplorer` object.
- Listing 8 (p. 1836) . Set the size and location of the GUI control panel.
- Listing 9 (p. 1837) . Register a listener object on the button.
- Listing 10 (p. 1838) . Prob12.java.
- Listing 11 (p. 1840) . Modified `PictureExplorer.java`.

4.4.3.3.2.3 Preview

In this module, I will show you how to extract color data from a selected pixel in a `PictureExplorer` object, and how to display the value in a text field.

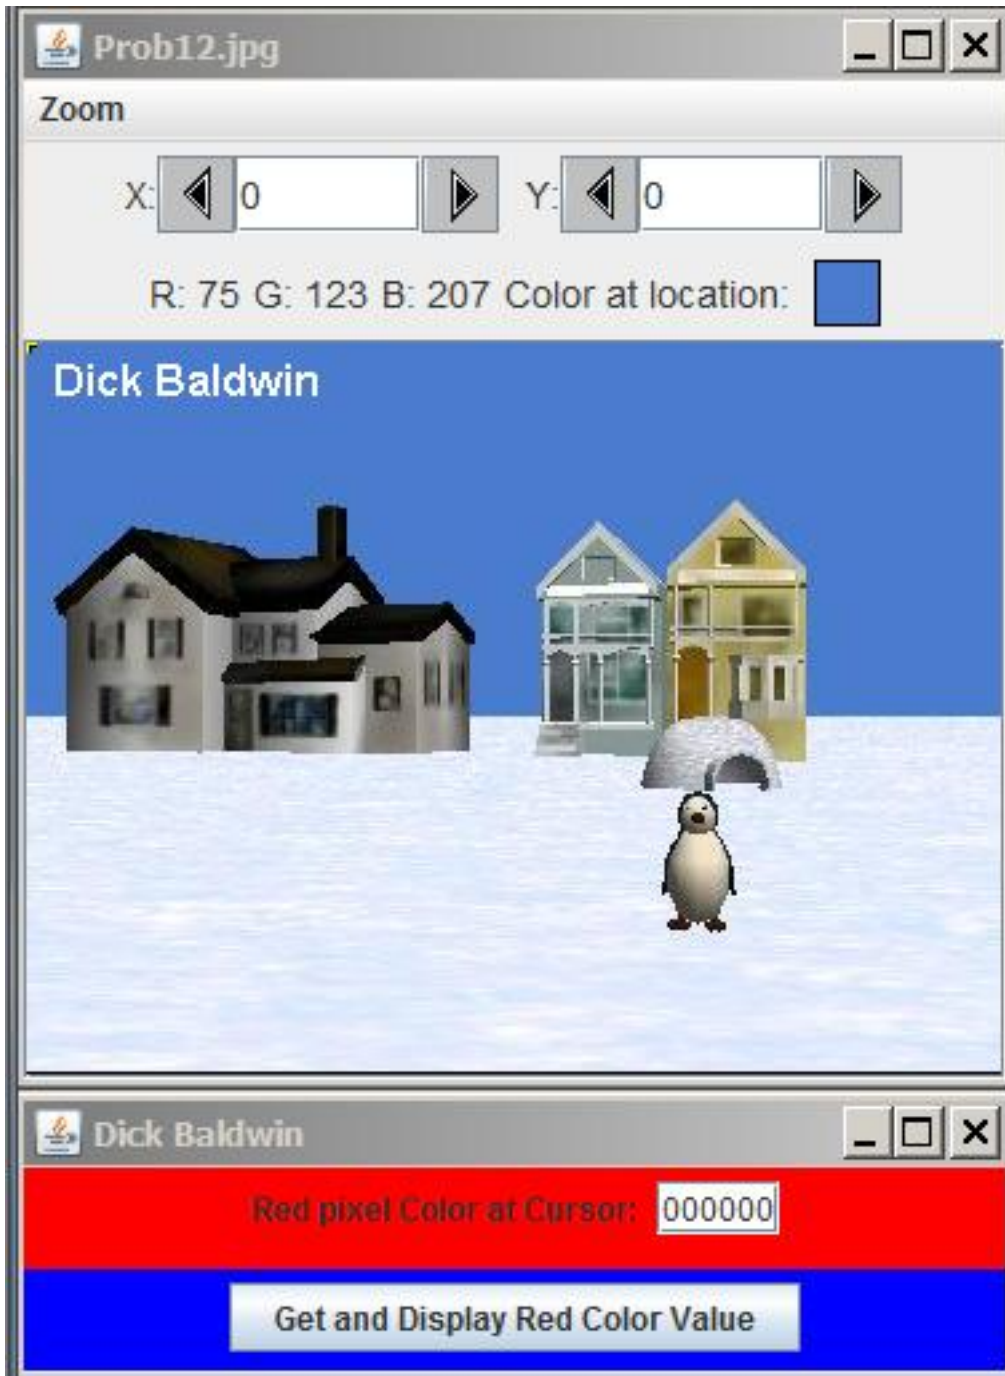

I will also show you how to disable the **X-button** in the `PictureExplorer` object, and how to get and use a reference to the `JFrame` object that serves as a container for the `PictureExplorer` object.

Program output at startup

Figure 1 (p. 1830) shows a screen shot of the program output at startup.

Note that the text field in the red panel near the bottom contains all zeros.

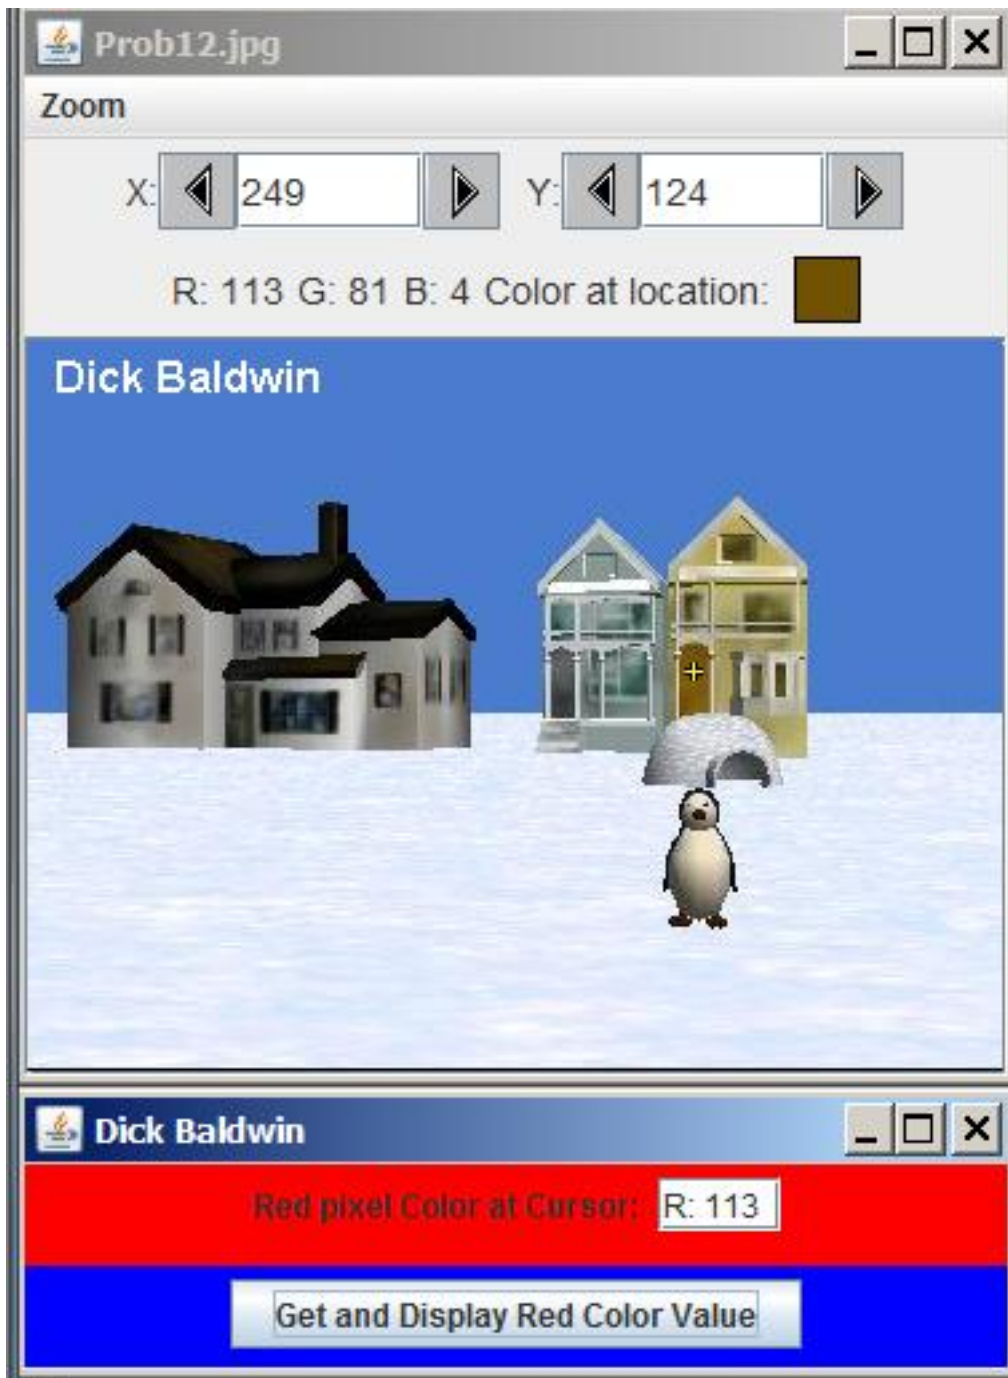

Figure 1 - Program output at startup.

Program output after clicking the button

Figure 2 (p. 1831) shows the screen output after moving the `PictureExplorer` crosshair cursor to the brown door immediately above the penguin, and clicking the button labeled *"Get and Display Red Color Value."*

Figure 2 - Program output after clicking the button.

The red color value

The text field near the bottom of Figure 2 (p. 1831) displays the red color value of the pixel at the location of the crosshair cursor on the door in the image.

Compare this value with the value of the red color value displayed near the top of the **PictureExplorer** object. You will see that they match.

4.4.3.3.2.4 Discussion and sample code

Two source code files are required for this program:

- The file named **Prob12.java**
- A modified version of Ericson's file named **PictureExplorer.java**

A complete listing of **Prob12.java** is shown in Listing 10 (p. 1838) .

A complete listing of the modified **PictureExplorer.java** file is shown in Listing 11 (p. 1840) .

Modifications to PictureExplorer.java

The modifications that I made can be found by searching the source code in Listing 11 (p. 1840) for the word "Baldwin".

The modifications were:

- I added a *getter* method to cause the red color value to be accessible from outside the **PictureExplorer** object.
- I added a *getter* method that returns a reference to the **JFrame** object containing the **PictureExplorer** object.
- I disabled the call to the **setDefaultCloseOperation** method for the **PictureExplorer** object.

Addition of getter methods

The code for the each of the new *getter* methods is shown in Listing 1 (p. 1833) .

These two methods simply return values that already exist in the **PictureExplorer** object.

Listing 1 - Addition of getter methods.

```

//===Methods added by Baldwin on 05/15/12=====//
//Method to get the red color value as text.
public String getRValue(){
    return rValue.getText();
} //end getRValue

//Method to get a reference to the JFrame containing
// the PictureExplorer object.
public JFrame getFrame(){
    return pictureFrame;
} //end getFrame()
//===End methods added by Baldwin on 05/15/12=====//

```

Table 4.303

Disabled the call to setDefaultCloseOperation method

Comment indicators were used to disable the call to the **setDefaultCloseOperation** method as shown in Listing 2 (p. 1834) .

This code was replaced by code that you will see later that causes the **JFrame** to *do nothing* when the X-button on the **PictureExplorer** object is clicked.

Listing 2 - Disabled the call to setDefaultCloseOperation method.

```

    /*Disabled by Baldwin on 5/15/12
    pictureFrame.setDefaultCloseOperation(
                                JFrame.DISPOSE_ON_CLOSE);
*/

```

Table 4.304**No more modifications**

That concludes the discussion of modifications to Ericson's **PictureExplorer** source code.

The driver class named Prob12

The driver class is shown in Listing 3 (p. 1834) .

There is nothing new here.

Listing 3 - The driver class for Prob12.

```

    public class Prob12{
    public static void main(String[] args){
        new Prob12Runner();
    }//end main method
} //end class Prob12

```

Table 4.305**Beginning of the class named Prob12Runner**

The class named **Prob12Runner** begins in Listing 4 (p. 1834) .

The code in Listing 4 (p. 1834) declares several instance variables and initializes some of them.

Listing 4 - Beginning of the class named Prob12Runner.

```

    class Prob12Runner extends JFrame{
    private JFrame explorerFrame = null;
    private PictureExplorer explorer = null;
    private Picture pix;

    private JPanel controlPanel = new JPanel();
    private JPanel colorPanel = new JPanel();
    private JPanel buttonPanel = new JPanel();

    private JTextField redField = new JTextField("000000");

    private JButton getDataButton = new JButton(
        "Get and Display Red Color Value");
    private String fileName = "Prob12.jpg";

```

Table 4.306

Beginning of the constructor

The constructor for the class named **Prob12Runner** begins in Listing 5 (p. 1835) .

The code in Listing 5 (p. 1835) performs the physical construction of the GUI control panel at the bottom of Figure 1 (p. 1830) .

The final position of the GUI control panel will be established after the size of the **PictureExplorer** object's **JFrame** is known.

Listing 5 - Beginning of the constructor.

```

        controlPanel.setLayout(new GridLayout(2,1));
        controlPanel.add(colorPanel);
        controlPanel.add(buttonPanel);

        colorPanel.setBackground(Color.RED);
        colorPanel.add(new JLabel(
            "Red pixel Color at Cursor: "));
        colorPanel.add(redField);

        buttonPanel.setBackground(Color.BLUE);
        buttonPanel.add(getDataButton);

        getContentPane().add(controlPanel);
        setTitle("Dick Baldwin");

        setVisible(true);

```

Table 4.307

Construct a Picture object

Listing 6 (p. 1835) creates a new **Picture** object, and adds a name to the picture before using it to construct a **PictureExplorer** object.

Listing 6 - Construct a Picture object.

```

        pix = new Picture(fileName);
        pix.addMessage("Dick Baldwin",10,20);

```

Table 4.308

Construct a PictureExplorer object

Listing 7 (p. 1836) begins by constructing a new **PictureExplorer** object that encapsulates the **Picture** object instantiated in Listing 6 (p. 1835) , and by saving a reference to the **PictureExplorer** object in the instance variable named **explorer** .

Listing 7 - Construct a PictureExplorer object.

```

explorer = new PictureExplorer(pix);

explorerFrame = explorer.getFrame();

explorerFrame.setDefaultCloseOperation(
    WindowConstants.DO_NOTHING_ON_CLOSE);

```

Table 4.309**Get and use a reference to the JFrame object**

Then Listing 7 (p. 1836) calls the **PictureExplorer** object's new **getFrame** method to get a reference to the **JFrame** object that contains the **PictureExplorer**.

This reference is used in Listing 7 (p. 1836) to call the **setDefaultCloseOperation** method to cause the **JFrame** to *do nothing* when the X-button on the **JFrame** is clicked.

The reference is also used in Listing 8 (p. 1836) to establish the size and location of the GUI control panel.

Set the size and location of the GUI control panel

Now that the **PictureExplorer** object exists, Listing 8 (p. 1836) sets the size and location of the GUI control panel as shown in Figure 1 (p. 1830).

Listing 8 - Set the size and location of the GUI control panel.

```

//Set the size of the control GUI.
setSize(explorerFrame.getWidth(),110);

//Set the location for the control GUI
setLocation(0,explorerFrame.getHeight());

//Set the default close operation for the control GUI.
setDefaultCloseOperation(
    WindowConstants.EXIT_ON_CLOSE);

```

Table 4.310

Note that it isn't necessary to guess about the actual height of the **JFrame** as was the case in an earlier module. The reference to the **JFrame** object provides that information.

Set the default close operation for the control GUI

Finally, Listing 8 (p. 1836) sets the default close operation on the control GUI to cause the program to terminate when the user clicks the X-button on the GUI.

Register a listener object on the button

Listing 9 (p. 1837) registers an **ActionListener** object on the button to cause it to call the **PictureExplorer** object's new **getRValue** method to get the red color value for the pixel at the current **PictureExplorer** crosshair cursor position, and to display that value in the text field as shown in Figure 2 (p. 1831) when the user clicks the button.

Listing 9 - Register a listener object on the button.

```

        getDataButton.addActionListener(
        new ActionListener(){
            public void actionPerformed(ActionEvent e){

                redField.setText(explorer.getRValue());

            }//end action performed
        }//end newActionListener
    );//end addActionListener
    //-----//

} //end constructor
} //end class Prob12Runner

```

Table 4.311

End of the program

Listing 9 (p. 1837) also signals the end of the constructor and the end of the class named **Prob12Runner**

4.4.3.3.2.5 Run the program

I encourage you to copy the code from Listing 10 (p. 1838) and Listing 11 (p. 1840) and download the image file named Prob12.jpg⁴⁴¹. Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.3.3.2.6 Summary

You learned how to extract color data from a selected pixel in a **PictureExplorer** object, and to display the value in a text field.

You also learned how to disable the X-button in the **PictureExplorer** object, and how to use a reference to the **JFrame** object that serves as a container for the **PictureExplorer** object.

4.4.3.3.2.7 What's next?

In the next module, you will learn how to handle document events on text fields containing color values. You will also learn how to create a color swatch.

4.4.3.3.2.8 Miscellaneous

This section contains a variety of miscellaneous information.

4.4.3.3.2.9 Complete program listings

Complete listings of the source code discussed in this module are shown in Listing 10 (p. 1838) and Listing 11 (p. 1840) below.

Listing 10 - Prob12.java.

```
/*File Prob12 Copyright 2012 R.G.Baldwin
```

The purpose of this program is to demonstrate how to get a color value from a PictureExplorer object and to display it in JTextField object.

It also demonstrates how to access and use a reference to a JFrame object that serves as the container for a PictureExplorer object.

Finally, it demonstrates how to disable the X-button in a PictureExplorer object.

Note that this program requires access to a modified version of the PictureExplorier class.

import javax.swing.border.*;

/*
05/15/12
Modified by Baldwin to add getter methods to cause
the following values to be accessible from outside the
PictureExplorer object:

Red color value

Reference to the JFrame containing the PictureExplorer
object.

```

Also disabled the call to `setDefaultCloseOperation`

```

*/

/**
 * Displays a picture and lets you explore the picture by displaying the x, y, red,
 * green, and blue values of the pixel at the cursor when you click a mouse button or
 * press and hold a mouse button while moving the cursor. It also lets you zoom in or
 * out. You can also type in a x and y value to see the color at that location.
 *

4.4.3.3.3.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

4.4.3.3.3.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

4.4.3.3.3.2.1.1 Figures

- Figure 1 (p. 1857) . Program output at startup.
- Figure 2 (p. 1858) . Program output after clicking the button.
- Figure 3 (p. 1858) . Program output after entering color values.

4.4.3.3.3.2.1.2 Listings

- Listing 1 (p. 1859) . The driver class.
- Listing 2 (p. 1859) . Beginning of the class named Prob13Runner.
- Listing 3 (p. 1860) . Beginning of constructor for Prob13Runner.
- Listing 4 (p. 1861) . Continue the constructor.
- Listing 5 (p. 1862) . Register a listener object on the button.
- Listing 6 (p. 1863) . Beginning of DocumentListener on Red text field.
- Listing 7 (p. 1863) . The removeUpdate method.
- Listing 8 (p. 1864) . The insertUpdate method.
- Listing 9 (p. 1865) . The paintColorSwatch method.
- Listing 10 (p. 1866) . Complete program listing.

4.4.3.3.3.3 Preview

In this module, I will show you how to handle document events on text fields containing color values.

I will also show you how to create a color swatch that displays the color indicated by the color values in the Red, Green, and Blue text fields.

Program output at startup

Figure 1 (p. 1857) shows the program output at startup.

Note that the color values in the Red, Green, and Blue text fields are all zero, the color of the square at the right end of the Green panel is black.

Recall that black is represented by Red, Green, and Blue color values of zero.

Figure 1 - Program output at startup.

Program output after clicking the button

Figure 2 (p. 1858) shows the program output after clicking the button labeled "Set Green Color."

Figure 2 - Program output after clicking the button.

Note that in Figure 2 (p. 1858) ,

- the color values in the Red and Blue text fields are zero,
- the color value in the Green text field is 255,
- the square (*color swatch*) at the right end of the green panel is green with a black outline
- the square is not transparent.

Recall that pure green is represented by Red and Blue color values of zero, with a Green color value of 255.

Program output after entering color values

Figure 3 (p. 1858) shows the program output after manually entering a value of 255 in the Red text field.

Note that

- the color values in the Red and Green text fields are 255,
- the color value in the Blue text field is 0, and
- the square at the right end of the green panel is yellow with a black outline.

Figure 3 - Program output after entering color values.

Recall that pure yellow is represented by Red and Green color values of 255, with a Blue color value of zero.

Color of square tracks color values in text fields

The square (*color swatch*) always has a black outline as shown in Figure 3 (p. 1858) .

The color in the swatch always tracks the color values in the text fields regardless of whether those values are changed manually, or they are changed by program code.

4.4.3.3.4 Discussion and sample code

A complete listing of the program discussed in this module is provided in Listing 10 (p. 1866) .

Will explain in fragments

I will break this program down and explain it in fragments.

The driver class

The driver class named **Prob13** is shown in Listing 1 (p. 1859) . There is nothing new here.

Listing 1 - The driver class.

```
public class Prob13{
public static void main(String[] args){
    new Prob13Runner();
} //end main method
} //end class Prob13
```

Table 4.312

Beginning of the class named Prob13Runner

The class named **Prob13Runner** begins in Listing 2 (p. 1859) , which declares several instance variables and initializes some of them.

Listing 2 - Beginning of the class named Prob13Runner .

```
class Prob13Runner extends JFrame{

private JPanel controlPanel = new JPanel();
private JPanel colorPanel = new JPanel();
private JPanel buttonPanel = new JPanel();
private JPanel colorIndicatorPanel = new JPanel();

private JTextField redField = new JTextField("000000");
private JTextField greenField =
    new JTextField("000000");
private JTextField blueField = new JTextField("000000");

private int redInt = 0;
private int greenInt = 0;
private int blueInt = 0;

private JButton setColorButton =
    new JButton("Set Green Color");
```

Table 4.313

Beginning of constructor for Prob13Runner

The constructor begins in Listing 3 (p. 1860) . The last two statements in Listing 3 (p. 1860) may be new to you.

The **JPanel** referred to by **colorIndicatorPanel** is the color swatch shown in Figure 3 (p. 1858) .

The last two statements in Listing 3 (p. 1860) control the border color, and the size of the **JPanel** (*color swatch*) object.

Listing 3 - Beginning of constructor for Prob13Runner.

```

public Prob13Runner(){//constructor

setDefaultCloseOperation(
    WindowConstants.EXIT_ON_CLOSE);

controlPanel.setLayout(new GridLayout(2,1));
controlPanel.add(colorPanel);
controlPanel.add(buttonPanel);

colorPanel.setBackground(Color.GREEN);
colorPanel.add(new JLabel("Red = "));
colorPanel.add(redField);
colorPanel.add(new JLabel(" Green = "));
colorPanel.add(greenField);
colorPanel.add(new JLabel(" Blue = "));
colorPanel.add(blueField);
colorPanel.add(colorIndicatorPanel);

colorIndicatorPanel.setBorder(
    new LineBorder(Color.black,1));
colorIndicatorPanel.setPreferredSize(
    new Dimension(20,20));

```

Table 4.314

The constructor continues in Listing 4 (p. 1861) .

There is nothing new in Listing 4 (p. 1861) with the possible exception of the call to the method named **paintColorSwatch** .

I will explain the method named **paintColorSwatch** later.

Listing 4 - Continue the constructor.

```
        buttonPanel.setBackground(Color.BLUE);
buttonPanel.add(setColorButton);

//Color the swatch for the first time.
paintColorSwatch();

//Add the controlPanel to the content pane, adjust to
// the correct size, and set the title.
getContentPane().add(controlPanel);
pack();
setTitle("Dick Baldwin");

//Make the GUI visible
setVisible(true);
```

Table 4.315**Register listeners on the user input components**

This program registers event listener objects on four input components:

One component is the button at the bottom of Figure 3 (p. 1858) labeled **Set Green Color**.

The other three components are the three text fields labeled **Red** , **Green** , and **Blue** shown in Figure 3 (p. 1858) .

The three event listeners that are registered on the text fields are very similar. Therefore, I will explain only one of them. You can view the code for the other two in Listing 10 (p. 1866) .

Register a listener object on the button

Listing 5 (p. 1862) registers an ActionListener object on the **JButton** object referred to by **setColorButton** .

You have seen code like this in numerous previous modules. Therefore, a detailed explanation of Listing 5 (p. 1862) should not be required here.

Listing 5 - Register a listener object on the button.

```

        setColorButton.addActionListener(
new ActionListener(){
    public void actionPerformed(ActionEvent e){
        //Set the color to green.
        redInt = 0;
        greenInt = 255;
        blueInt = 0;

        //Show the color values in the text fields.
        redField.setText("" + redInt);
        greenField.setText("" + greenInt);
        blueField.setText("" + blueInt);

        }//end action performed
    }//end new ActionListener
});//end addActionListener

```

Table 4.316**The DocumentListener interface**

The **DocumentListener** interface can be described briefly as follows:

"Interface for an observer to register to receive notifications of changes to a text document."

This interface is implemented by numerous classes including the **JTextField** class. As mentioned earlier, the **Red**, **Green**, and **Blue** text fields in Figure 3 (p. 1858) are objects of the **JTextField** class and therefore implement the **DocumentListener** interface.

DocumentListener methods

The **DocumentListener** interface declares the follow three methods:

- **changedUpdate**
 - Gives notification that an attribute or set of attributes changed.
- **insertUpdate**
 - Gives notification that there was an insert into the document.
- **removeUpdate**
 - Gives notification that a portion of the document has been removed.

Only the **insertUpdate** and **removeUpdate** methods are of interest in this program. Therefore, the **changedUpdate** method will be implemented as an empty method.

Beginning of DocumentListener

Listing 6 (p. 1863) shows the beginning of the definition, instantiation, and registration of a **DocumentListener** object on the object of type **Document** that is encapsulated in the Red text field.

Listing 6 - Beginning of DocumentListener on Red text field.

```

    redField.getDocument().addDocumentListener(
new DocumentListener(){

    public void changedUpdate(DocumentEvent e){
        //Empty method - not needed
    }//end changedUpdate
}

```

Table 4.317

Note that registration of the listener object in this case has an additional level of indirection (*getDocument*) as compared to the registration of the listener on the JButton in Listing 5 (p. 1862) . In other words, the listener is not registered on the text field. Instead, it is registered on the document encapsulated in the text field.

This listener will respond when the contents of the text field are modified, either by the program, or by the user.

(As explained earlier, the **changedUpdate** method is defined as an empty method.)

The removeUpdate method

Listing 7 (p. 1863) shows the **removeUpdate** method in its entirety.

Listing 7 - The removeUpdate method.

```

    public void removeUpdate(DocumentEvent e){
    try{
        redInt = Integer.parseInt(
                                redField.getText());
        if((redInt >= 0) && (redInt <= 255)){
            paintColorSwatch();
        }//end if
    }catch(Exception ex){
        //do nothing on exception
    }//end catch
    }//end removeUpdate

```

Table 4.318**Behavior of the removeUpdate method**

Listing 7 (p. 1863) calls the static **parseInt** method of the **Integer** class to convert the **String** contents of the Red text field into a value of type **int** .

The **parseInt** method can throw a **NumberFormatException** if the string does not contain a parsable integer.

The possibility of a **NumberFormatException** , (which is a checked exception) requires that the call to the **parseInt** method be enclosed in a **try-catch** block.

In this program, the **catch** block causes the **removeUpdate** method to **do nothing** if the contents of the text field cannot be converted into an **int** , which causes a **NumberFormatException** to be thrown

If a **NumberFormatException** exception is not thrown, the return value from the **parseInt** method is stored in an instance variable named **redInt** .

If the value of **redInt** is between 0 and 255 inclusive, Listing 7 (p. 1863) calls the method named **paintColorSwatch** , causing the color swatch to be repainted, using the **Red** value, along with the **Green** and **Blue** values computed elsewhere.

The insertUpdate method

The **insertUpdate** method is shown in Listing 8 (p. 1864) .

The behavior of the **insertUpdate** method is essentially the same as the behavior of the **removeUpdate** method explained earlier. Therefore, an explanation of the **insertUpdate** method should not be needed.

Listing 8 - The insertUpdate method.

```

    public void insertUpdate(DocumentEvent e){
    try{
        redInt = Integer.parseInt(
                                redField.getText());
        if((redInt >= 0) && (redInt <= 255)){
            paintColorSwatch();
        }//end if
    }catch(Exception ex){
        //do nothing on exception
    }//end catch
    }//end insertUpdate
    //-----//

    }//end new DocumentListener
    );//end addDocumentListener

```

Table 4.319

The end of the class definition

Listing 8 (p. 1864) also signals the end of the anonymous class definition that began in Listing 6 (p. 1863) .

The Green and Blue text fields

The Green and Blue text fields are processed using very similar **DocumentListener** objects as used for the Red text field. You can view that code in Listing 10 (p. 1866) .

That ends the discussion of the constructor for the class named **Prob13Runner** .

The method named paintColorSwatch

There were earlier references to a method named **paintColorSwatch** . The code for the **paintColorSwatch** method is shown in Listing 9 (p. 1865) .

Listing 9 - The paintColorSwatch method.

continued on next page

```

        private void paintColorSwatch(){
        colorIndicatorPanel.setBackground(
                new Color(redInt,greenInt,blueInt));
        }//end paintColorSwatch
        //-----//
} //end class Prob13Runner

```

Table 4.320

The **paintColorSwatch** method sets the background color for the **JPanel** object that represents the color swatch, using values of red, green, and blue that are computed elsewhere in the program.

The end of the program

Listing 9 (p. 1865) also signals the end of the class named **Prob13Runner** and the end of the program.

4.4.3.3.3.5 Run the program

I encourage you to copy the code from Listing 10 (p. 1866) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.3.3.3.6 Summary

In this lesson, you learned how to handle document events on text fields containing color values. You also learned how to create a color swatch.

4.4.3.3.3.7 What's next?

In the next module, you will learn how to use a **JColorChooser** object to specify a color in any one of five different ways.

4.4.3.3.3.8 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java OOP: Handling document events on a text field and creating a color swatch
- File: Java1326.htm
- Published: 09/11/12
- Revised: 02/06/16

Disclaimers: Financial : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

In the past, unknown individuals have copied my modules from cnx.org, converted them to Kindle books, and placed them for sale on Amazon.com showing me as the author. I neither receive compensation for those sales nor do I know who does receive compensation. If you purchase such a book, please be aware that it is a copy of a module that is freely available on cnx.org and that it was made and published without my prior knowledge.

Affiliation : I am a professor of Computer Information Technology at Austin Community College in Austin, TX.

4.4.3.3.9 Complete program listing

A complete listing of the source code discussed in this module is shown in Listing 10 (p. 1866) .

Listing 10 - Complete program listing.

```
/*File Prob13 Copyright 2012 R.G.Baldwin
```

This program handles document events on the contents of text fields containing color values.

The values are used to create a color swatch that displays the color indicated by the color values in the red, green, and blue text fields.

```

4.4.3.3.4.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

4.4.3.3.4.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

4.4.3.3.4.2.1.1 Figures

- Figure 1 (p. 1872) . Program output at startup.
- Figure 2 (p. 1872) . Program output after clicking the Choose Color button.
- Figure 3 (p. 1873) . Program output after selecting a reddish color and clicking the OK button.
- Figure 4 (p. 1874) . Program output after clicking the Darker button.
- Figure 5 (p. 1876) . The showDialog method.

4.4.3.3.4.2.1.2 Listings

- Listing 1 (p. 1875) . Event handler for the Choose Color button.
- Listing 2 (p. 1875) . Show the JColorChooser object.
- Listing 3 (p. 1877) . Darkening the color.
- Listing 4 (p. 1878) . Complete program listing.

4.4.3.3.4.3 Preview

In this module, you will learn how to use a **JColorChooser** object to specify a color in any one of five different ways:

- Swatches
- HSV
- HSL
- RGB
- CMYK

The details regarding the five different ways are not explained. Instead, an understanding of the five ways for specifying a color is left as an exercise for the student.

This module concentrates on the programming aspects of the color chooser as opposed to the aesthetic aspects of the color chooser.

You will also learn how to create brighter and darker shades of a given color.

What is a JColorChooser object?

According to the Java documentation,

"JColorChooser provides a pane of controls designed to allow a user to manipulate and select a color."

Program output at startup

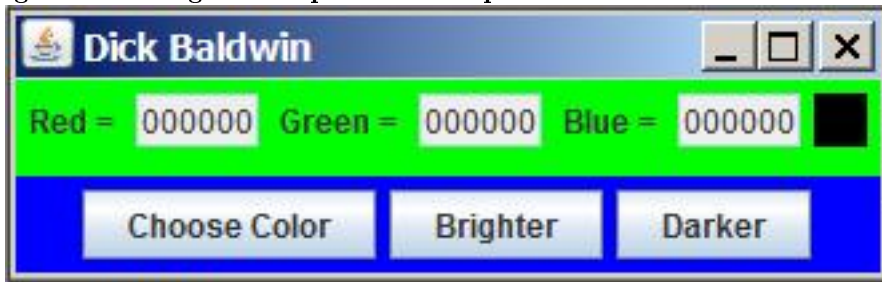

A complete listing of the program discussed in this module is provided in Listing 4 (p. 1878) near the end of the module.

Figure 1 (p. 1872) shows the program output at startup.

The program output is a GUI containing

- three text fields, one each for red, green, and blue color values
- three labels that identify the contents of each text field
- a button labeled **Choose Color**
- two buttons labeled **Brighter** and **Darker**
- a square **color swatch** whose color reflects the color specified by the color component values in the text fields

Figure 1 - Program output at startup.

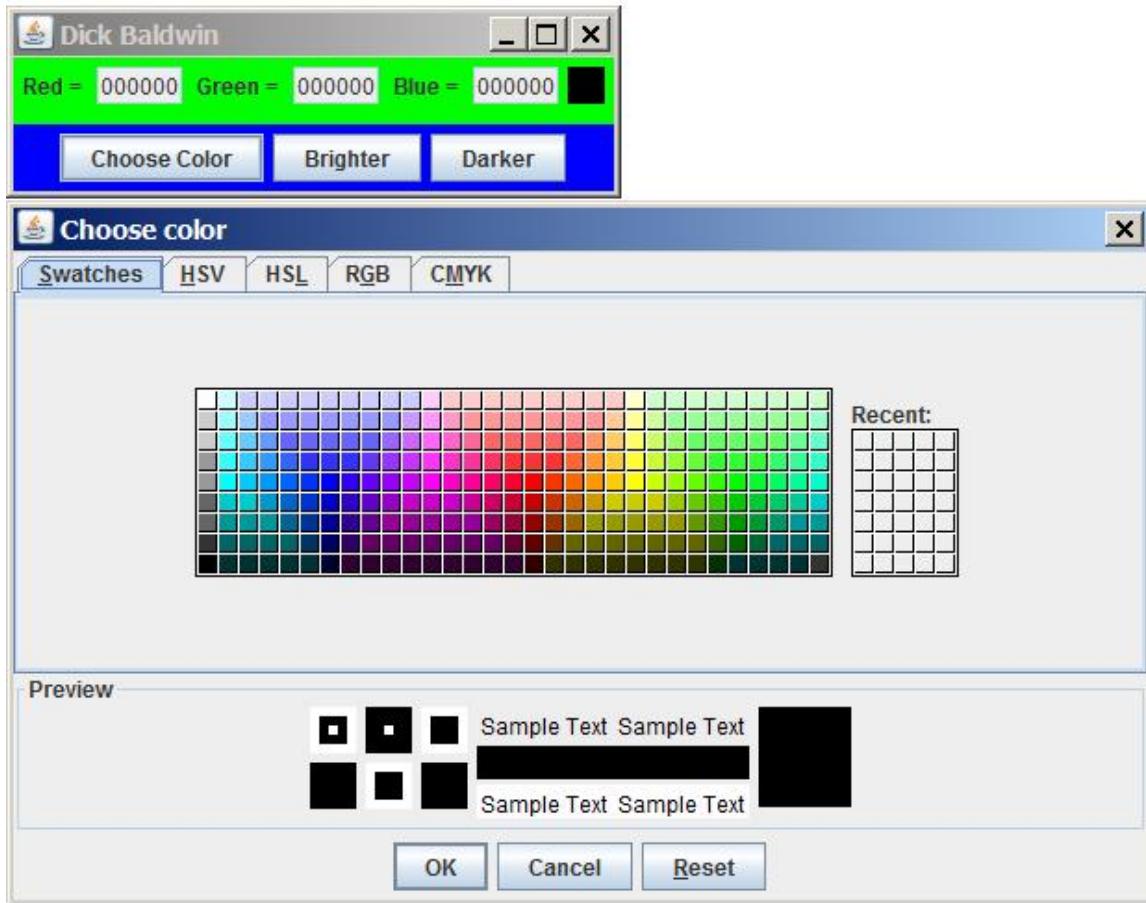

Program output after clicking the Choose Color button.

Figure 2 (p. 1872) shows the result of clicking the **Choose Color** button shown in Figure 1 (p. 1872).

The bottom image in Figure 2 (p. 1872) is an object of the **JColorChooser** class.

(The color chooser object doesn't actually appear below the GUI as shown in Figure 2 (p. 1872). Instead, it appears in the upper-left corner of the screen and hides the GUI. I manually dragged it down below the GUI to produce this image.)

Figure 2 - Program output after clicking the Choose Color button.

The initial color selection

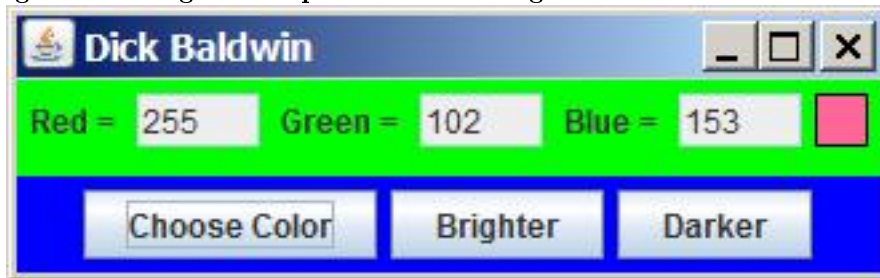

Note in Figure 2 (p. 1872) that the selected color when the color chooser appears matches the color of the square color swatch in Figure 1 (p. 1872) (*black*)

Program output after selecting a reddish color and clicking the OK button.

Figure 3 (p. 1873) shows the result of

- selecting a reddish color in the color chooser, and
- clicking the OK button in the color chooser.

Figure3 - Program output after selecting a reddish color and clicking the OK button.

New color in the GUI

Note in Figure 3 (p. 1873) that

- the color selected in the color chooser now appears in the square color swatch in Figure 3 (p. 1873)

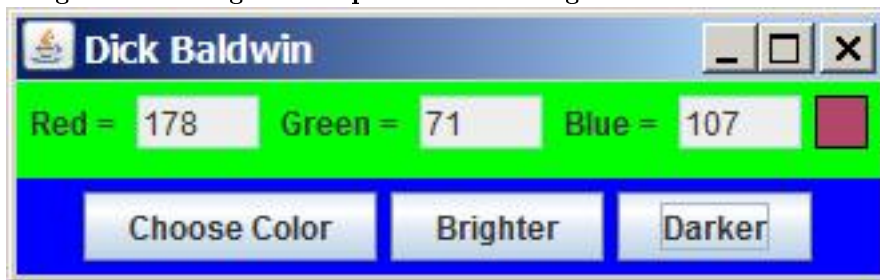

- the color swatch in Figure 3 (p. 1873) has a black border
- the color values in the three text fields describe the color showing in the swatch

(The color in the swatch is based on the three color values in the text fields.)

Program output after clicking the Darker button.

Figure 4 (p. 1874) shows the result of clicking the **Darker** button once.

Figure 4 - Program output after clicking the Darker button.

A darker color

The color swatch in Figure 4 (p. 1874) shows a darker version of the color swatch shown in Figure 3 (p. 1873) .

The numeric color values in Figure 4 (p. 1874) describe the color in the color swatch, and are lower than the corresponding color values in Figure 3 (p. 1873)

A brighter color

Although not demonstrated here, the color in the swatch could be made brighter by clicking the **Brighter** button.

If you click the **Darker** button enough times, the color will go to black. Similarly, if you click the **Brighter** button enough times, the color will go to white.

4.4.3.3.4.4 Discussion and sample code

A complete listing of the program is provided in Listing 4 (p. 1878) .

Much of the code in this program is very similar to code that I explained in earlier modules. Therefore, I won't repeat those explanations here. Instead, I will concentrate on the code that is new and different.

Given that caveat, I will skip all the way down to the event handler for the **Choose Color** button.

Event handler for the Choose Color button

Listing 1 (p. 1875) defines, instantiates, and registers an **ActionListener** object on the **Choose Color** button.

Listing 1 - Event handler for the Choose Color button.

```

        chooseButton.addActionListener(
new ActionListener(){
    public void actionPerformed(ActionEvent e){
        Color selColor = JColorChooser.showDialog(
            chooseButton,"Choose color",new Color(
                redInt,greenInt,blueInt));
        if(selColor != null){
            //Don't change the color if the user cancels
            // out.
            redField.setText("" + selColor.getRed());
            greenField.setText("" + selColor.getGreen());
            blueField.setText("" + selColor.getBlue());
        }//end if

        }//end action performed
    }//end new ActionListener
);//end addActionListener

```

Table 4.321**Show the JColorChooser object**

Listing 2 (p. 1875) shows the code, (extracted from Listing 1 (p. 1875)) that causes the **color chooser** to appear on the screen.

Listing 2 - Show the JColorChooser object.

```

Color selColor = JColorChooser.showDialog(
    chooseButton,
    "Choose color",
    new Color(redInt,greenInt,blueInt));

```

Table 4.322**Call the static showDialog method**

Listing 2 (p. 1875) calls the static **showDialog** method of the **JColorChooser** class. Figure 5 (p. 1876) provides information for the **showDialog** method.

Figure 5 - The showDialog method.*continued on next page*

```

public static Color showDialog(
    Component component,
    String title,
    Color initialColor)
    throws HeadlessException

```

Shows a modal color-chooser dialog and blocks until the dialog is hidden. If the user presses the "OK" button, then this method hides/disposes the dialog and returns the selected color. If the user presses the "Cancel" button or closes the dialog without pressing "OK", then this method hides/disposes the dialog and returns null.

Parameters:

component - the parent Component for the dialog
title - the String containing the dialog's title
initialColor - the initial Color set when the color-chooser is shown

Returns:

the selected color or null if the user opted out

Table 4.323

A straightforward explanation

The behavior of the dialog is explained in Figure 5 (p. 1876) and shouldn't require further explanation.

Parameters to the showDialog method

A comparison of Listing 2 (p. 1875) and Figure 5 (p. 1876) shows how the color chooser is integrated into the program.

Perhaps the most important aspects of that integration are the *third parameter* and the *return value*.

The third parameter

The third parameter is an anonymous **Color** object that matches the color specified by the text fields in the GUI, which determine the color of the swatch.

Thus, the initial color for the color chooser matches the color of the swatch in the GUI when the color chooser first appears.

The return value

The return value from the color chooser is a reference to an object of type **Color**, which is saved in a variable named `selColor`.

Processing the return value

Returning to the code in Listing 1 (p. 1875),

- if the return value is not null,
- the color components of the return value are converted to strings and
- stored in the red, green, and blue text fields.

What happens next?

You learned in an earlier module that if the values stored in any of the three text fields changes for any reason, **DocumentListener** objects registered on the three text fields cause the color of the swatch to change to match the new values of the color components.

Thus, the color that is chosen by the user from the color chooser modifies the values in the text fields causing the color of the swatch in the GUI to match the chosen color.

Darkening and brightening the color

Listing 3 (p. 1877) shows an **ActionListener** object being registered on the button labeled **Darker** in Figure 1 (p. 1872) .

Listing 3 - Darkening the color.

```
darkerButton.addActionListener(
new ActionListener(){
public void actionPerformed(ActionEvent e){
    Color color = new Color(
        redInt,greenInt,blueInt).darker();
    redField.setText("" + color.getRed());
    greenField.setText("" + color.getGreen());
    blueField.setText("" + color.getBlue());
    }//end action performed
};//end newActionListener
);//end addActionListener
```

Table 4.324

The darkening action listener

This code creates a new **Color** object that matches the color values in the three text fields. Then it calls the **darker** method on that **Color** object causing its color to be darkened. Then it extracts the color components from the darker **Color** object and stores those values in the text fields.

This, in turn, causes the color swatch to change to match the new color values.

A brightening event handler

A similar event handler is registered on the button labeled **Brighter** in Figure 1 (p. 1872) .

This code, which you can view in Listing 4 (p. 1878) calls the **brighter** method instead of the **darker** method on the **Color** object.

End of story

That concludes the explanation of material that is new and different in this program.

4.4.3.3.4.5 Run the program

I encourage you to copy the code from Listing 4 (p. 1878) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.3.3.4.6 Summary

In this module, you will learned how to use a **JColorChooser** object to specify a color in any one of five different ways.

You also learned how to create brighter and darker shades of a given color.

4.4.3.3.4.7 What's next?

In the next module, you will learn how to write an editor program that you can use to modify the colors in an image on a pixel-by-pixel basis.

4.4.3.3.4.8 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java OOP: Using a JColorChooser object
- File: Java3128.htm

Disclaimers: Financial : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

In the past, unknown individuals have copied my modules from cnx.org, converted them to Kindle books, and placed them for sale on Amazon.com showing me as the author. I neither receive compensation for those sales nor do I know who does receive compensation. If you purchase such a book, please be aware that it is a copy of a module that is freely available on cnx.org and that it was made and published without my prior knowledge.

Affiliation : I am a professor of Computer Information Technology at Austin Community College in Austin, TX.

4.4.3.3.4.9 Complete program listing

A complete listing of the source code discussed in this module is shown in Listing 4 (p. 1878) .

Listing 4 - Complete program listing.

```
/*File Prob14 Copyright 2012 R.G.Baldwin
```

Old material:

This program services document events on the contents of text fields containing color values.

The values are used to create a color swatch that displays the color indicated by the color values in the red, green, and blue text fields.

New material:

Demonstrates how to create and use a JColorChooser dialog. Also demonstrates use of the darker and brighter methods. Also demonstrates how to cause JTextField objects to be non-editable.

- Summary (p. 1893)
- Miscellaneous (p. 1893)
- Complete program listing (p. 1894)

4.4.3.3.5.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

The program described in this module requires the use of the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library⁴⁴⁵.

4.4.3.3.5.2.1 Viewing tip

I recommend that you open another copy of this document in a separate browser window and use the following links to easily find and view the figures and listings while you are reading about them.

⁴⁴⁴This content is available online at <<http://cnx.org/content/m44926/1.6/>>.

⁴⁴⁵<http://cnx.org/content/m44148/latest/>

4.4.3.3.5.2.1.1 Figures

- Figure 1 (p. 1885) . Program output at startup.
- Figure 2 (p. 1886) . Program output after zooming the image.
- Figure 3 (p. 1887) . Program output after changing the pixel color to yellow.

4.4.3.3.5.2.1.2 Listings

- Listing 1 (p. 1889) . Code for methods that were added.
- Listing 2 (p. 1889) . Modified setDefaultCloseOperation method.
- Listing 3 (p. 1890) . Beginning of ActionListener registered on update button.
- Listing 4 (p. 1890) . Convert zoom factor to type String.
- Listing 5 (p. 1891) . Set pixel color in original image.
- Listing 6 (p. 1891) . Create and populate a new PictureExplorer object.
- Listing 7 (p. 1892) . Call the mousePressed method.
- Listing 8 (p. 1893) . Set the zoom state.
- Listing 9 (p. 1894) . Complete listing of Prob15.
- Listing 10 (p. 1901) . Complete listing of modified PictureExplorer class.

4.4.3.3.5.3 Preview

In this module, you will learn how to write an editor program that you can use to modify the colors in an image on a pixel-by-pixel basis.

Such a program could be useful, for example, for manually correcting "red eye" problems in digital images.

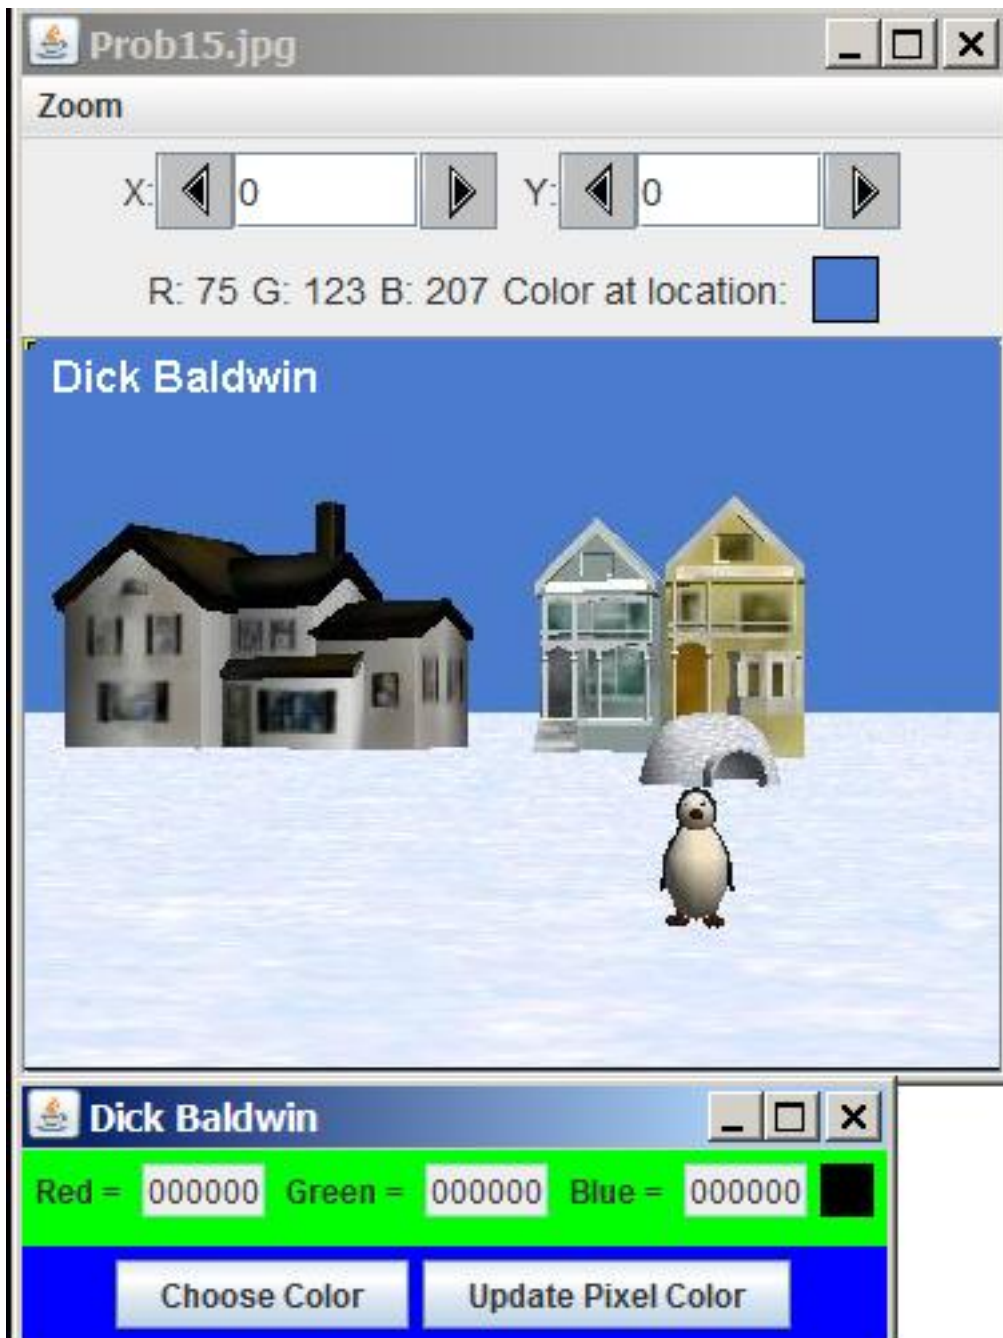

Program output at startup

Figure 1 (p. 1885) shows the program output at startup.

The output consists of

- an Ericson **PictureExplorer** object displaying an image of a penguin, and
- a color manipulation GUI similar to those discussed in earlier modules.

Figure 1 - Program output at startup.

Program output after zooming the image

Figure 2 (p. 1886) shows the program output after placing the **PictureExplorer** cursor on the penguin's nose, and zooming the **PictureExplorer** image by 500%

If you look carefully, you should be able to see the crosshair cursor on the penguin's nose.

Figure 2 - Program output after zooming the image.

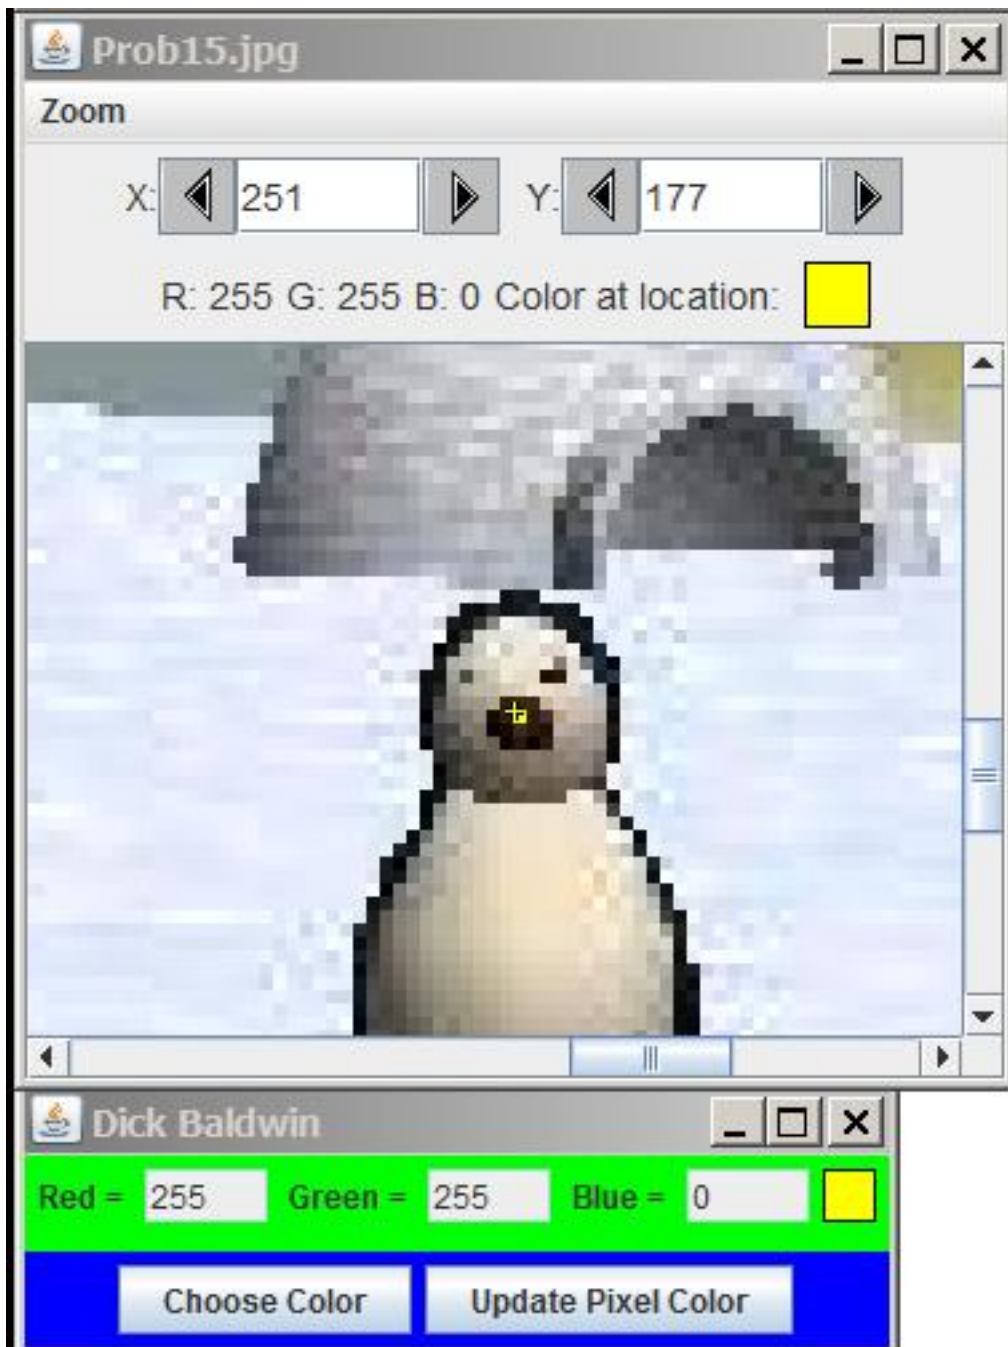

Program output after changing the pixel color to yellow

Figure 3 (p. 1887) shows the result of selecting the color yellow with the GUI, and clicking the button labeled **Update Pixel Color**

If you look carefully, you should see that the pixel next to the crosshair cursor on the penguin's nose has changed from black to yellow.

Figure 3 - Program output after changing the pixel color to yellow.

4.4.3.3.5.4 Discussion and sample code

This program requires modifications to Ericson's `PictureExplorer` class. I will deal with that issue first.

A complete listing of the modified version of the `PictureExplorer` class is shown in Listing 10 (p. 1901).

Changes to Ericson's `PictureExplorer` class

The `PictureExplorer` class was modified to add *getter* methods to cause the following values to be accessible from outside the object:

- int xIndex
- int yIndex
- double zoomFactor
- JFrame pictureFrame

Also the call to the `setDefaultCloseOperation` method was disabled.

Code for methods that were added

Listing 1 (p. 1889) shows the code for the methods that were added to the `PictureExplorer` class.

Listing 1 - Code for methods that were added.

```

    //Method to get the xIndex value.
public int getXIndex(){
    return xIndex;
} //end getXIndex

//Method to get the yIndex value.
public int getYIndex(){
    return yIndex;
} //end getYIndex

//Method to get the zoomFactor value.
public double getZoomFactor(){
    return zoomFactor;
} //end getZoomFactor

//Method to get a reference to the frame
public JFrame getFrame(){
    return pictureFrame;
} //end getFrame()

```

Table 4.325

Modified `setDefaultCloseOperation` method

Listing 2 (p. 1889) shows the modified version of the `setDefaultCloseOperation` method.

Note the parameter that is passed to the method when it is called.

Listing 2 - Modified `setDefaultCloseOperation` method.

```

explorerFrame.setDefaultCloseOperation(
    WindowConstants.DO_NOTHING_ON_CLOSE);

```

Table 4.326

Similar to previous code

Much of the code in this program is similar to code that I explained in earlier modules, and I won't repeat those explanations.

I will skip down to the event handler registered on the button labeled **Update Pixel Color** in Figure 1 (p. 1885) . That code begins in Listing 3 (p. 1890) .

Listing 3 - Beginning of ActionListener registered on update button.

```
updateButton.addActionListener(
new ActionListener(){
public void actionPerformed(ActionEvent e){

//Get properties of PictureExplorer object.
xIndex = explorer.getXIndex();
yIndex = explorer.getYIndex();
zoomFactor = explorer.getZoomFactor();
```

Table 4.327

Important to preserve properties

The only thing that changes when you click the **update** button is the color of the pixel at the crosshair cursor.

Therefore, the program must preserve the state of the explorer object including such items as the zoom factor and the location of crosshair cursor.

Listing 3 (p. 1890) gets and saves the property values that determine the state of the explorer object.

Convert zoom factor to String

The **getZoomFactor** method returns the zoom factor as type **double** . However, we need the zoom factor as type **String** . The code in Listing 4 (p. 1890) converts the zoom factor to type **String** .

Listing 4 - Convert zoom factor to type String.

```
//Save zoom factor as a string.
String zoomString = "100%";
if(zoomFactor == 0.25){
zoomString = "25%";
}else if(zoomFactor == 0.50){
zoomString = "50%";
}else if(zoomFactor == 0.75){
zoomString = "75%";
}else if(zoomFactor == 1.0){
zoomString = "100%";
}else if(zoomFactor == 1.5){
zoomString = "150%";
}else if(zoomFactor == 2.0){
zoomString = "200%";
}else if(zoomFactor == 5.0){
zoomString = "500%";
}else{
zoomString = "100%";//in case no match
} //end else
```

Table 4.328

Set pixel color in original image

The code in Listing 5 (p. 1891)

- creates a new **Color** object based on the values in the text fields of Figure 3 (p. 1887) , and
- changes the color of the corresponding pixel in the original image to the new color.

At this point, the color of the pixel in the original image has been modified.

Listing 5 - Set pixel color in original image.

```
Color newColor = new Color(
    redInt,greenInt,blueInt);
pix.getPixel(xIndex,yIndex).setColor(newColor);
```

Table 4.329

Create and populate a new PictureExplorer object

Listing 6 (p. 1891) begins by disposing of the original **PictureExplorer** object. Then Listing 6 (p. 1891) creates a new **PictureExplorer** object containing the modified image.

Finally Listing 6 (p. 1891) calls the **setDefaultCloseOperation** on the **JFrame** that houses the **PictureExplorer** object disabling the X-button in the upper-right corner.

Listing 6 - Create and populate a new PictureExplorer object.

```
//Dispose of the existing explorer and create a
// new one.
explorerFrame.dispose();

explorer = new PictureExplorer(pix);

//Get reference to the new frame
explorerFrame = explorer.getFrame();
explorerFrame.setDefaultCloseOperation(
    WindowConstants.DO_NOTHING_ON_CLOSE);
```

Table 4.330

Set the state of the PictureExplorer object

You will probably need to study the event handling code in the **PictureExplorer** class to fully understand the remaining code in this discussion.

When you click the image in the **PictureExplorer** object, a **MouseListener** object registered on the **PictureExplorer** object calls the **mousePressed** method belonging to that object

Simulate a physical click

We can simulate a physical click on that image by calling the same method from outside the **PictureExplorer** object.

Call the `mousePressed` method

Listing 7 (p. 1892) calls the `mousePressed` method on the `PictureExplorer` object passing the crosshair coordinates as parameters. Other parameters are also passed to satisfy the requirements of the `mousePressed` method.

(I will leave it as an exercise for the student to investigate those other parameters.)

Listing 7 - Call the `mousePressed` method.

```

//Now set the state of the new explorer.

//Simulate a mouse pressed event in the picture
// to set the cursor and the text in the
// coordinate fields.
explorer.mousePressed(new MouseEvent(
    new JButton("dummy component"),
    MouseEvent.MOUSE_PRESSED,
    (long)0,
    0,
    xIndex,
    yIndex,
    0,
    false));

```

Table 4.331

`PictureExplorer` object handles crosshair cursor

The code in Ericson's `mousePressed` method takes care of all the requirements that result from setting the location of the crosshair cursor, such as setting the coordinate values in the `PictureExplorer` object's text fields shown in Figure 3 (p. 1887) .

Set the zoom state

Manually selecting a zoom level from the `Zoom` menu in the `PictureExplorer` object causes the `actionPerformed` method belonging to an `ActionListener` object registered on the `PictureExplorer` object to be executed.

As before, we can simulate the manual selection of a `Zoom` menu value by calling that `actionPerformed` method from outside the object.

Set the zoom state

Listing 8 (p. 1893) calls Ericson's `actionPerformed` method, passing the `String` representation of the zoom factor as a parameter.

(I will leave it as an exercise for the student to investigate the other parameters.)

Listing 8 - Set the zoom state.

continued on next page

```

        //Simulate an action event on the zoom menu to
        // set the zoom.
        explorer.actionPerformed(new ActionEvent(
            explorer,
            ActionEvent.ACTION_PERFORMED,
            zoomString));

    }//end actionPerformed
} //end newActionListener
); //end addActionListener

```

Table 4.332

Conclusion of discussion

That concludes the discussion of the **ActionListener** object registered on the button labeled **Update Pixel Color** in Figure 1 (p. 1885) .

It also concludes the discussion of the program.

4.4.3.3.5.5 Run the program

I encourage you to copy the code from Listing 9 (p. 1894) and Listing 10 (p. 1901) and download the image file named Prob15.jpg⁴⁴⁶ . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

4.4.3.3.5.6 Summary

In this module, you learned how to write an editor program that you can use to modify the colors in an image on a pixel-by-pixel basis.

4.4.3.3.5.7 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java OOP: A Pixel Color Editor
- File: Java3130.htm
- Published: 09/11/12
- Revised: 02/06/16

Disclaimers: Financial : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

4.4.3.3.5.8 Complete program listing

Complete listings of the source code discussed in this module are shown in Listing 9 (p. 1894) and Listing 10 (p. 1901) below.

Listing 9 - Complete listing of Prob15.

```
/*File Prob15 Copyright 2012 R.G.Baldwin
```

The purpose of this program is demonstrate one way to change the color of a pixel in a Picture object that is encapsulated in a PictureExplorer object.

The pixel to be modified is selected by placing the cursor in the PictureExplorer object.

4.4.3.4 Practice Programs

4.4.3.4.1 Java OOP: ITSE 2317 Practice Programs 1⁴⁴⁷**4.4.3.4.1.1 ITSE2317 - Java Programming (Intermediate) - Practice Test 1**

- Java and Media Library Version Requirements (p. 1919)
- Input Image Files (p. 1919)
- Solution source code files (p. 1919)
- Output Images (p. 1919)
- New Classes (p. 1919)
- Hints (p. 1920)
- Testing Your Programs (p. 1920)
- Program Specifications (p. 1920)
 - Program 1 (p. 1920)
 - Program 2 (p. 1921)
 - Program 3 (p. 1923)
 - Program 4 (p. 1925)
 - Program 5 (p. 1927)
- Miscellaneous Information (p. 1930)

4.4.3.4.1.1.1 Java and Media Library Version Requirements

Your programs must be compatible with Sun's Standard Edition JDK Version 1.7 or later.

Some of the programs on this test require you to use the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library⁴⁴⁸.

4.4.3.4.1.1.2 Input Image Files

Links are provided within the individual program specifications for downloading zip files that contain any image files that may be required to write, compile, and test your programs.

4.4.3.4.1.1.3 Solution source code files

The downloadable zip files mentioned above also contains source code files for the programming solutions. You can compile and execute those programs using procedures described in Java OOP: The Guzdial-Ericson Multimedia Class Library⁴⁴⁹.

4.4.3.4.1.1.4 Output Images

Your output image(s) must match my output image(s) in every respect including color, size, position, etc. Don't forget to display your name in the output image(s) as shown.

4.4.3.4.1.1.5 New Classes

You may define new classes and add import directives as needed to cause your programs to behave as required, but you may not modify the class definitions for the given classes named ProbXX when such class definitions are provided.

⁴⁴⁷This content is available online at <<http://cnx.org/content/m44264/1.5/>>.

⁴⁴⁸<http://cnx.org/content/m44148/latest/>

⁴⁴⁹<http://cnx.org/content/m44148/latest/>

4.4.3.4.1.1.6 Hints

For some of the programs, you may first need to deduce the algorithm used to transform the input image into the output image, and then write a working program that implements that algorithm. In some cases, you may need to compare numeric color values for corresponding pixels in the input and output images in order to deduce the algorithm.

You can obtain those color values using the following procedure:

1. Click the download link for the zip files that contain input image files and solution source code files. Use the capabilities of your browser to download and save the contents of those zip files.
2. If necessary, replace calls to the `show` method in my source code with calls to the `explore` method to force the program to display the output images in a `PictureExplorer` window.
3. Compile and run the source code.
4. Write, compile, and run a simple Java program that will display each input image file in a `PictureExplorer` window.
5. Use the input and output `PictureExplorer` windows to compare the input and output color values on a pixel by pixel basis.

You may find other useful hints in my online tutorials and slides for this course.

4.4.3.4.1.1.7 Testing Your Programs

You can compile and execute your program by following the instructions given at Java OOP: The Guzdial-Ericson Multimedia Class Library ⁴⁵⁰.

4.4.3.4.1.1.8 Program Specifications

4.4.3.4.1.1.8.1 Program 1

```

Write a program named Prob01 that uses the class definition shown below and Ericson's media library along with the image file named Prob01.jpg to produce the graphic output image shown in Figure 1 (p. 1921) below.

Click here ⁴⁵¹ to download a zip file containing the required image file along with the source code for a solution.

Contrary to the general instructions given above, you may not define any new classes to cause your program to behave as required.

You must copy and modify (if necessary) the media classes named World.java, Turtle.java, and SimpleTurtle.java to cause your program to produce the required output. Don't forget to compile these classes after you modify them.

In addition to the output image, your program must produce the following output on the command-line screen, and must substitute your name for mine wherever my name appears both in the image and on the command-line screen:

```
Dick Baldwin
Picture, filename Prob01.jpg height 274 width 365
Dick Baldwin
Dick Baldwin
Dick Baldwin
Dick Baldwin
Dick Baldwin
*****/
```

⁴⁵⁰<http://cnx.org/content/m44148/latest/>

⁴⁵¹<http://cnx.org/content/m44264/latest/Prob01solution.zip>

```

public class Prob01{
    //DO NOT MODIFY THE CODE IN THIS CLASS DEFINITION.
    public static void main(String[] args){
        World mars = new World(200,250);
        Turtle joe = new Turtle(mars);
        joe.forward();
        Turtle bill = new Turtle(mars);
        bill.moveTo(50,125);
        Turtle sue = new Turtle(mars);
        sue.moveTo(150,125);
        Turtle tom = new Turtle(mars);
        tom.moveTo(100,225);
    }//end main method
} //end class Prob01
//End program specifications.

```

Figure 1 - Required output images for Prob01.

4.4.3.4.1.1.8.2 Program 2

Listing 2 - Write the Java application described below.

```
/*File Prob02 Copyright 2012 R.G.Baldwin
```

Write a program named Prob02 that uses the class definition shown below and Ericson's media library to produce the graphic output image shown in Figure 2 (p. 1922) below.

Click here ⁴⁵² to download a zip file containing source code for a solution.

⁴⁵²<http://cnx.org/content/m44264/latest/Prob02solution.zip>

Contrary to the general instructions given above, you may not define any new classes to cause your program to behave as required.

You must copy and modify (if necessary) the media classes named Turtle.java, and SimpleTurtle.java to cause your program to produce the required output. Don't forget to compile these classes after you modify them.

In addition to the output image, your program must produce the following output on the command-line screen, and must substitute your name for mine wherever my name appears both in the image and on the command-line screen:

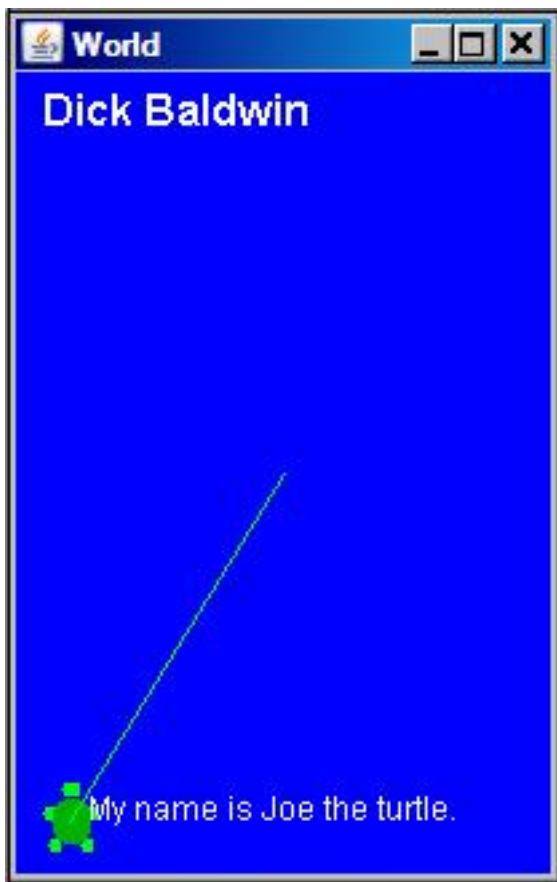

```

    Dick Baldwin
My name is Joe the turtle.
*****/
import java.awt.Color;

public class Prob02{
    //DO NOT MODIFY THE CODE IN THIS CLASS DEFINITION.
    public static void main(String[] args){
        World mars = new World(200,300);
        Turtle joe = new Turtle(mars,"Joe");
        joe.moveTo(20,280);
        joe.setInfoColor(Color.WHITE);
        joe.setShowInfo(true);
        System.out.println(joe);
    }//end main method
} //end class Prob02
//End program specifications.

```

Figure 2 - Required output images for Prob02.

4.4.3.4.1.1.8.3 Program 3

Listing 3 - Write the Java application described below.

```
/*File Prob03 Copyright 2012 R.G.Baldwin
```

Write a program named Prob03 that uses Ericson’s media library to produce the graphic output images shown in Figure 3 (p. 1923) and Figure 4 (p. 1924) below.

Click here ⁴⁵³ to download a zip file containing the source code for a solution.

The image shown in Figure 3 (p. 1923) is the image that appears on the screen when the program starts running. The image shown in Figure 4 (p. 1924) is what you should see when you click the button at the bottom of the world.

You must copy and modify (if necessary) the media class named World.java, to cause your program to produce the required output with the required behavior. Don’t forget to compile that class after you modify it.

This program adds a JButton object to the SOUTH location of the World object as shown in Figure 3 (p. 1923) .

The program initially displays an empty white world. When the user clicks the button, the world’s background color changes to blue, a turtle appears in the center of the World, and the student’s name appears near the top of the world.

Figure 3 - The first of two required output images for Prob03.

⁴⁵³<http://cnx.org/content/m44264/latest/Prob03solution.zip>

Figure 4 - The second of two required output images for Prob03.

4.4.3.4.1.1.8.4 Program 4

Listing 4 - Write the Java application described below.

```
/*File Prob04 Copyright 2012 R.G.Baldwin
```

Write a program named Prob04 that uses Ericson's media library to produce the graphic output images shown in Figure 5 (p. 1926) , Figure 6 (p. 1926) , and Figure 7 (p. 1927) below.

Click here ⁴⁵⁴ to download a zip file containing the source code for a solution.

Figure 5 (p. 1926) shows the image that appears on the screen when the program starts running. Figure 6 (p. 1926) shows what you should see after you have clicked the button at the bottom of the world one time. Figure 6 (p. 1926) shows what you should see after you have clicked the button sixteen times.

You must copy and modify the media classes named World.java and SimplePicture.java, to cause your program to produce the required output with the required behavior. Don't forget to compile those classes after you modify them.

This program adds a JButton object to the SOUTH location of the World object as shown in Figure 5 (p. 1926) .

The following description is intended to guide you in writing your program. However, you must run my version of the program and replicate it exactly. I recommend that you run the two programs side-by-side and compare their appearance and behavior each time you click both programs.

⁴⁵⁴<http://cnx.org/content/m44264/latest/Prob04solution.zip>

The program initially displays an empty white world with a button at the bottom. When the user clicks the button, the world's background color changes to green, a turtle appears in the bottom right of the World, and the student's name appears near the top of the world in blue. The turtle has a blue body and a red shell.

When you click the button again, the background changes to yellow, the student's name changes to red, and the turtle changes to a red body with a blue shell. The turtle turns 90 degrees left and moves forward 100 pixels plus the value of a click counter. As a result, the turtle leaves a blue trail.

On the next click, the colors revert to the same as before, the turtle turns 90 degrees left and moves forward 100 pixels plus the value of the click counter leaving a red trail.

This cycle repeats on each click with the turtle's trail drawing a square spiral of increasing size with red lines on the top and bottom of the spiral and blue lines on the right and left of the spiral.

Figure 5 - Required output image for Prob04.

Figure 6 - Required output image for Prob04.

Figure 7 - Required output image for Prob04.

4.4.3.4.1.1.8.5 Program 5

Listing 5 - Write the Java application described below.

```
/*File Prob05 Copyright 2012 R.G.Baldwin
```

Write a program named Prob05 that uses Ericson's media library to produce the graphic output image shown in Figure 8 (p. 1928) , Figure 9 (p. 1928) , and Figure 10 (p. 1929) below.

Click here ⁴⁵⁵ to download a zip file containing the source code for a solution.

Figure 8 (p. 1928) shows the image that appears on the screen when the program starts running. Figure 9 (p. 1928) shows what you should see after you have entered numeric values into the angle and distance fields and have clicked the Move button. Figure 10 (p. 1929) is similar to what you should see after doing the above several times for different numeric values.

You must copy and modify the media class named World.java to cause your program to produce the required output with the required behavior. Don't forget to compile World.java after you modify it.

This program adds two buttons, two labels, and two text fields to form a GUI at the bottom of the World object.

If you enter numeric values into the angle and distance fields and then click the Move button, the turtle will turn by that angle in degrees and move by that distance in pixels.

The program must terminate and return control to the operating system when you click the Quit button.

Note that the GUI at the bottom of the World object is comprised of AWT components instead of Swing components.

Figure 8 - Required output image for Prob05.

Figure 9 - Required output image for Prob05.

4.4.3.4.2 Java OOP: ITSE 2317 Practice Programs 2⁴⁵⁶

4.4.3.4.2.1 ITSE2317 - Java Programming (Intermediate) - Practice Test 2

- Java and Media Library Version Requirements (p. 1932)
- Input Image Files (p. 1932)
- Solution source code files (p. 1932)
- Output Images (p. 1932)
- New Classes (p. 1932)
- Hints (p. 1933)
- Testing Your Programs (p. 1933)
- Program Specifications (p. 1933)
 - Program 1 (p. 1933)
 - Program 2 (p. 1936)
 - Program 3 (p. 1937)
 - Program 4 (p. 1938)
 - Program 5 (p. 1940)
- Miscellaneous Information (p. 1942)

4.4.3.4.2.1.1 Java and Media Library Version Requirements

Your programs must be compatible with Sun's Standard Edition JDK Version 1.7 or later.

Some of the programs on this test require you to use the Guzdial-Ericson multimedia class library. You will find download, installation, and usage instructions for the library at Java OOP: The Guzdial-Ericson Multimedia Class Library⁴⁵⁷.

4.4.3.4.2.1.2 Input Image Files

Links are provided within the individual program specifications for downloading zip files that contain any image files that may be required to write, compile, and test your programs.

4.4.3.4.2.1.3 Solution source code files

The downloadable zip files mentioned above also contains source code files for the programming solutions. You can compile and execute those programs using procedures described in Java OOP: The Guzdial-Ericson Multimedia Class Library⁴⁵⁸.

4.4.3.4.2.1.4 Output Images

Your output image(s) must match my output image(s) in every respect including color, size, position, etc. Don't forget to display your name in the output image(s) as shown.

4.4.3.4.2.1.5 New Classes

You may define new classes and add import directives as needed to cause your programs to behave as required, but you may not modify the class definitions for the given classes named ProbXX when such class definitions are provided.

⁴⁵⁶This content is available online at <<http://cnx.org/content/m44265/1.6/>>.

⁴⁵⁷<http://cnx.org/content/m44148/latest/>

⁴⁵⁸<http://cnx.org/content/m44148/latest/>

4.4.3.4.2.1.6 Hints

For some of the programs, you may first need to deduce the algorithm used to transform the input image into the output image, and then write a working program that implements that algorithm. In some cases, you may need to compare numeric color values for corresponding pixels in the input and output images in order to deduce the algorithm.

You can obtain those color values using the following procedure:

1. Click the download link for the zip files that contain input image files and solution source code files. Use the capabilities of your browser to download and save the contents of those zip files.
2. If necessary, replace calls to the `show` method in my source code with calls to the `explore` method to force the program to display the output images in a `PictureExplorer` window.
3. Compile and run the source code.
4. Write, compile, and run a simple Java program that will display each input image file in a `PictureExplorer` window.
5. Use the input and output `PictureExplorer` windows to compare the input and output color values on a pixel by pixel basis.

You may find other useful hints in my online tutorials and slides for this course.

4.4.3.4.2.1.7 Testing Your Programs

You can compile and execute your program by following the instructions given at Java OOP: The Guzdial-Ericson Multimedia Class Library ⁴⁵⁹.

4.4.3.4.2.1.8 Program Specifications

4.4.3.4.2.1.8.1 Program 1

Listing 1 - Write the Java application described below.

```
/*File Prob01 Copyright 2012 R.G.Baldwin
```

Write a program named Prob01 that uses the class definition shown below and Ericson's media library along with the image files named Prob01a.jpg and Prob01b.jpg to produce the graphic output images shown in Figure 1 (p. 1934), Figure 2 (p. 1934), and Figure 3 (p. 1935) below.

Click here ⁴⁶⁰ to download a zip file containing the required image files along with the source code for a solution.

Just in case you haven't noticed it, the image in Figure 3 (p. 1935) contains a partially transparent image of a butterfly superimposed and centered on the beach image.

In order to write this program, you must modify the class from Ericson's media library named SimplePicture. Your modifications must make it possible for you to display a partially transparent image on top of another image with the background image showing through. The degree of transparency can range from being completely transparent at one extreme to being totally opaque at the other extreme. In this case, the butterfly image is about 37-percent opaque. Don't forget to compile the SimplePicture class after you modify it.

You will probably need to do some outside research in order to write this program. For example, you will need to learn about the following topics and probably some other topics as well:

- Alpha transparency
- BufferedImage objects of TYPE_INT_ARGB
- The representation of a pixel as type int.
- Bit manipulation of pixels.

⁴⁵⁹<http://cnx.org/content/m44148/latest/>

⁴⁶⁰<http://cnx.org/content/m44265/latest/Prob01solution.zip>

- The drawImage method of the Graphics class.

In addition to the output images described above, your program must produce the following output on the command-line screen, and must substitute your name for mine wherever my name appears both in the images and on the command-line screen:

```

Dick Baldwin.
Dick Baldwin
Picture, filename Prob01a.jpg height 118 width 100
Picture, filename Prob01b.jpg height 240 width 320
Picture, filename None height 101 width 77
*****/
import java.awt.Color;
import java.awt.Graphics;
import java.awt.Image;

public class Prob01{
    //DO NOT MODIFY THE CODE IN THIS CLASS DEFINITION.
    public static void main(String[] args){
        Picture[] pictures = new Prob01Runner().run();
        System.out.println(pictures[0]);
        System.out.println(pictures[1]);
        System.out.println(pictures[2]);
    }//end main method
}//end class Prob01
//End program specifications.

```

Figure 1 - The first of three required output images for Prob01.

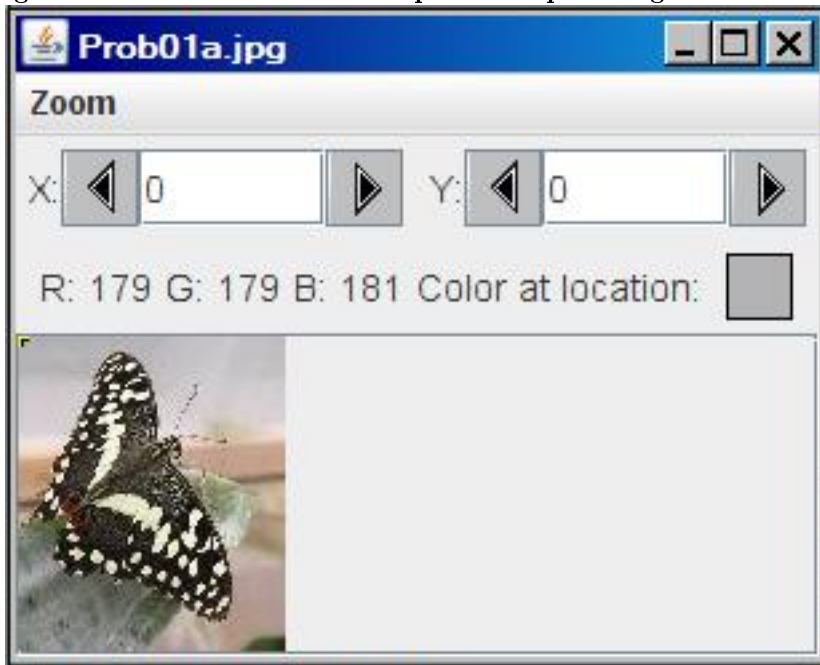

Figure 2 - The second of three required output images for Prob01.

Figure 3 - The third of three required output images for Prob01.

4.4.3.4.2.1.8.2 Program 2

Listing 2 - Write the Java application described below.

```
/*File Prob02 Copyright 2012 R.G.Baldwin
```

Write a program named Prob02 that uses Ericson's media library along with the image files named Prob02a.jpg and Prob02b.jpg to produce the graphic output images shown in Figure 4 (p. 1936) below.

Click here ⁴⁶¹ to download a zip file containing the required image files along with the source code for a solution.

The top image shown in Figure 4 (p. 1936) is a beach scene with a partially opaque butterfly superimposed on the beach scene. The bottom image is a slider that is used to control the percent opacity of the butterfly image.

At startup, the slider is positioned at the 50-percent mark and the opacity of the butterfly is 50 percent.

As you move the slider to the right, the butterfly becomes more opaque, becoming totally opaque when the slider is positioned at 100 percent. As you move the slider to the left, the butterfly becomes less opaque, becoming totally transparent when the slider is positioned at 0 percent.

In order to write this program, you must modify the class from Ericson's media library named SimplePicture. Your modifications must make it possible for you to display a partially transparent image on top of another image with the background image showing through.

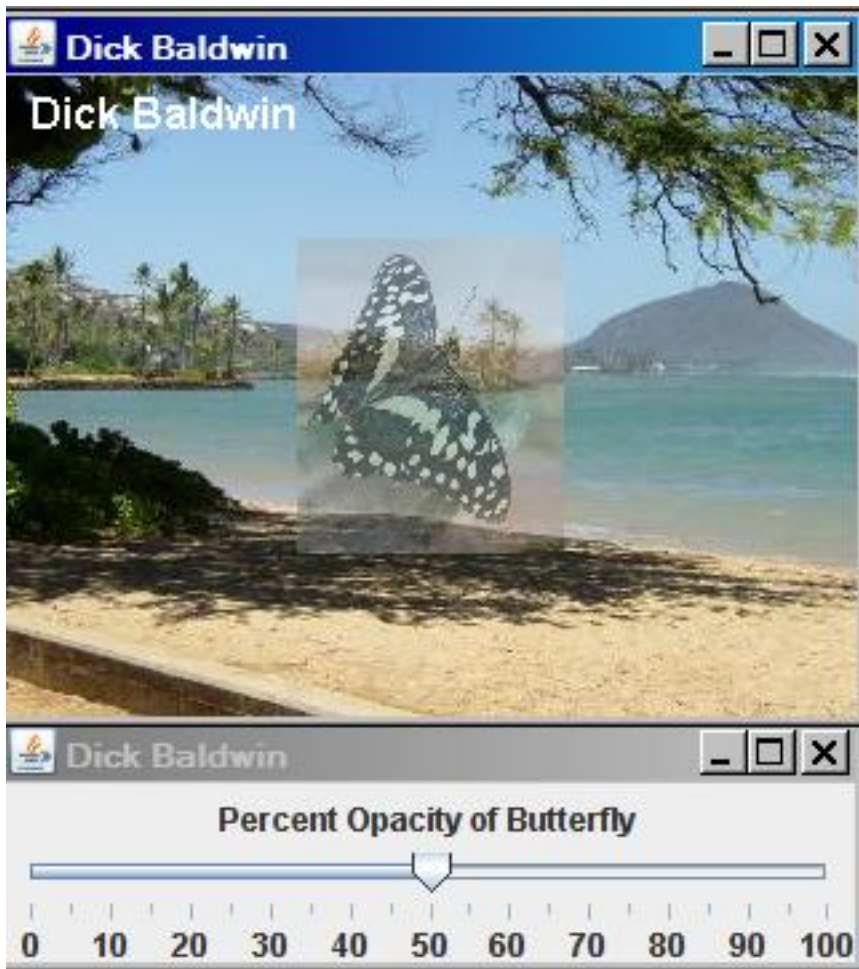

Your modification must also make it possible to display your name in the dark blue banner at the top of the image of the beach scene.

The program must terminate and return control to the operating system when you click the large X in the upper- right corner of the GUI containing the slider.

In order to improve the responsiveness and memory utilization of the program, you should instantiate all of the Picture objects that the program needs at startup, and should not instantiate additional Picture objects when handling events fired by the slider.

Figure 4 - Required output images for Prob02.

⁴⁶¹<http://cnx.org/content/m44265/latest/Prob02solution.zip>

4.4.3.4.2.1.8.3 Program 3

Listing 3 - Write the Java application described below.

```
/*File Prob03 Copyright 2012 R.G.Baldwin
```

Write a program named Prob03 that uses Ericson's media library along with the image file named Prob3.jpg to produce the graphic output images shown in Figure 5 (p. 1938) below.

Click here ⁴⁶² to download a zip file containing the required image file along with the source code for a solution.

The top image shown in Figure 5 (p. 1938) is an image of a butterfly to which an edge detection algorithm has been applied. The bottom image is a slider that is used to control the edge-detection threshold.

The edge-detection algorithm performs edge detection on a Picture object by rows and also by columns. All edges that are detected by processing adjacent pixels on a row are marked in red. All edges that are detected by processing adjacent pixels on a column are marked in black. If a pixel is determined to be on an edge using both approaches, it ends up being black. If an edge is not detected, the corresponding pixel is marked in white.

At startup, the slider is positioned at the 50-percent mark and the image has been edge-detected using a threshold value of 50. As you move the slider to the right, the threshold increases up to a value of 100, which in turn causes the amount of white area in the image to increase. As you move the slider to the left,

⁴⁶²<http://cnx.org/content/m44265/latest/Prob03solution.zip>

the threshold decreases down to a value of zero, which in turn causes the amount of white area in the image to decrease.

The program must terminate and return control to the operating system when you click the large X in the upper- right corner of the GUI containing the slider.

Figure 5 - Required output images for Prob03.

4.4.3.4.2.1.8.4 Program 4

Listing 4 - Write the Java application described below.

```
/*File Prob04 Copyright 2012 R.G.Baldwin
```

Write a program named Prob04 that uses Ericson's media library along with the image files named Prob04a.jpg and Prob04b.jpg to produce the graphic output images shown in Figure 6 (p. 1939) and Figure 7 (p. 1939) below.

Click here ⁴⁶³ to download a zip file containing the required image files along with the source code for a solution.

The top image shown in Figure 6 (p. 1939) is a butterfly image. The image immediately below that one is a slider that is used to control a scale factor that is applied to an image of a beach.

At startup, the slider is positioned at the zero-percent mark (*at the far left*) and the beach image is too small to be seen in the upper-left corner of the butterfly image.

⁴⁶³<http://cnx.org/content/m44265/latest/Prob04solution.zip>

As you move the slider to the right, an image of a beach emerges from the upper-left corner covering the image of the butterfly.

Figure 7 (p. 1939) shows the result of moving the slider to the 50-percent mark.

The size of the beach image increases and decreases smoothly as you move the slider back and forth. The upper-left corner of the beach image is always in the upper-left corner of the butterfly image. The butterfly becomes completely covered by the beach image when the slider is positioned at 100 percent (*the far right*).

The program must terminate and return control to the operating system when you click the large X in the upper-right corner of the GUI containing the slider.

Figure 6 - Required output images for Prob04.

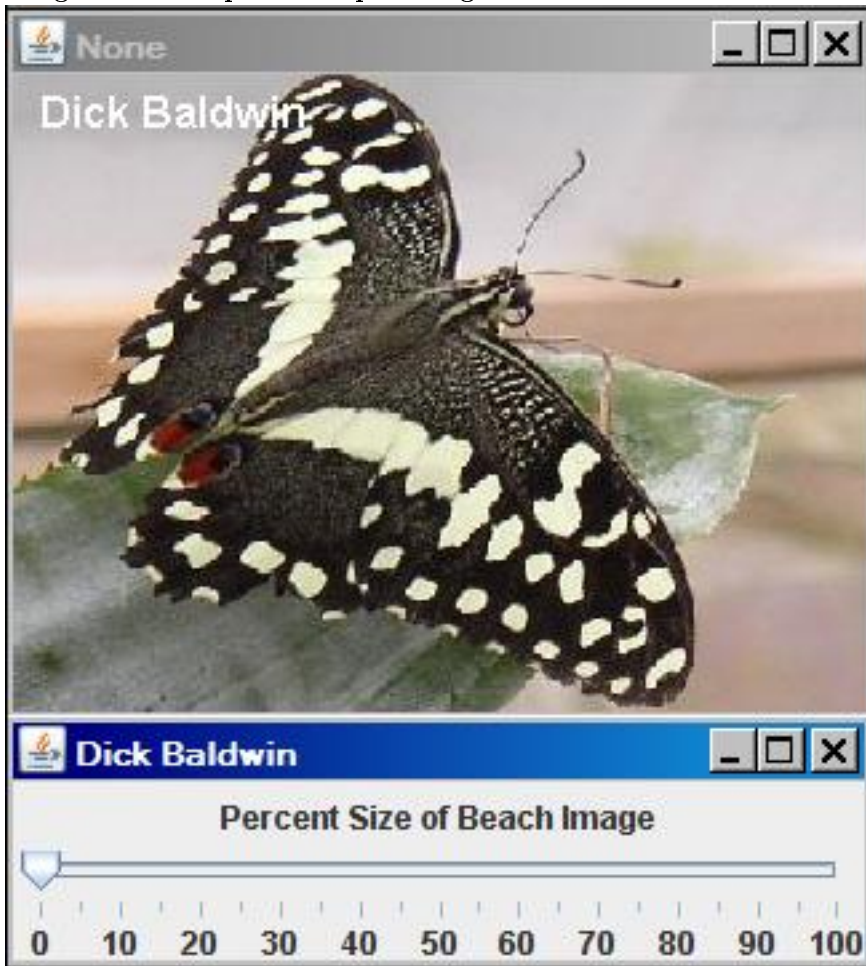

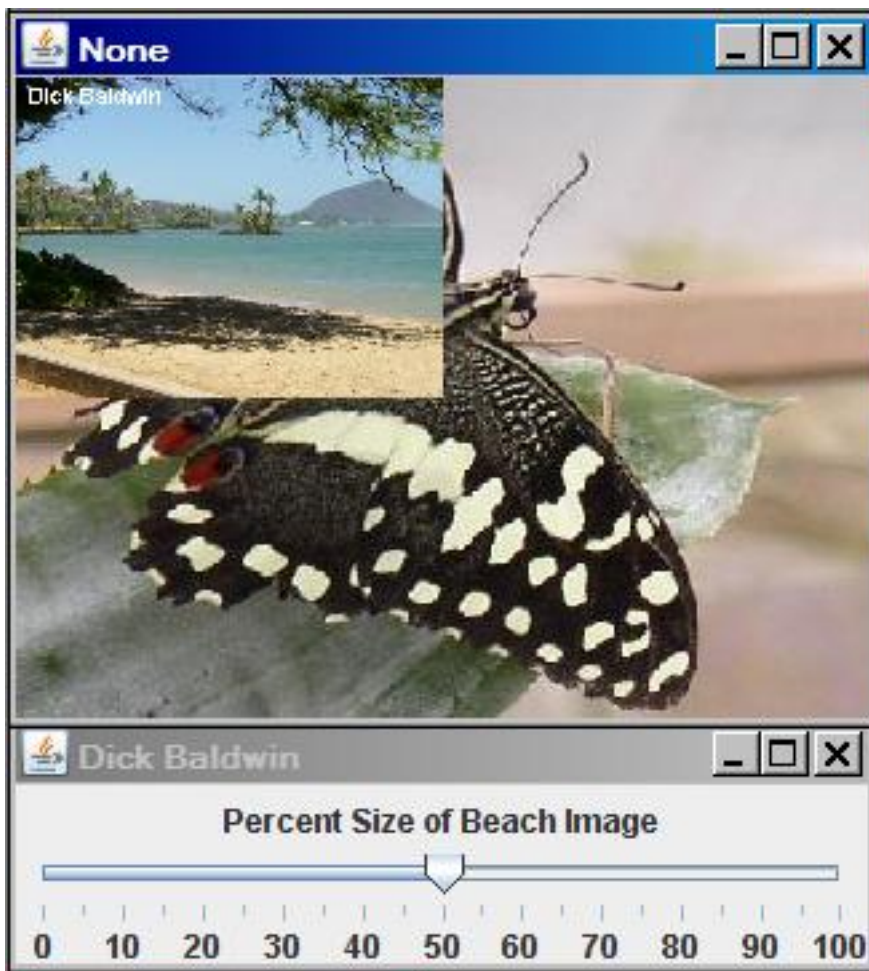

Figure 7 - Required output image for Prob04.

4.4.3.4.2.1.8.5 Program 5

Listing 5 - Write the Java application described below.

```
/*File Prob05 Copyright 2012 R.G.Baldwin
```

Write a program named Prob05 that uses Ericson's media library along with the image file named Prob05.jpg to produce the graphic output images shown in Figure 8 (p. 1941) and Figure 9 (p. 1941) below.

Click here ⁴⁶⁴ to download a zip file containing the required image file along with the source code for a solution.

The top image in Figure 8 (p. 1941) is a butterfly image. The image of the butterfly can be rotated in its picture by any angle ranging from -360 degrees to +360 degrees.

The image immediately below that one is a slider that is used to control the rotation angle that is applied to the butterfly image.

At startup, the slider is positioned at the zero-degrees mark (*in the center*) and the butterfly image is displayed with no rotation. As you move the slider to the right, the butterfly image rotates clockwise around its center through an angle that can be as large as 360 degrees.

Figure 9 (p. 1941) shows the result of moving the slider to the +120-degree mark.

As you move the slider to the left, the butterfly image rotates counter-clockwise around its center through an angle that can be as large as -360 degrees.

⁴⁶⁴<http://cnx.org/content/m44265/latest/Prob05solution.zip>

The butterfly image rotates smoothly around its center as you move the slider back and forth. The program must terminate and return control to the operating system when you click the large X in the upper- right corner of the GUI containing the slider.

Figure 8 - Required output image for Prob05.

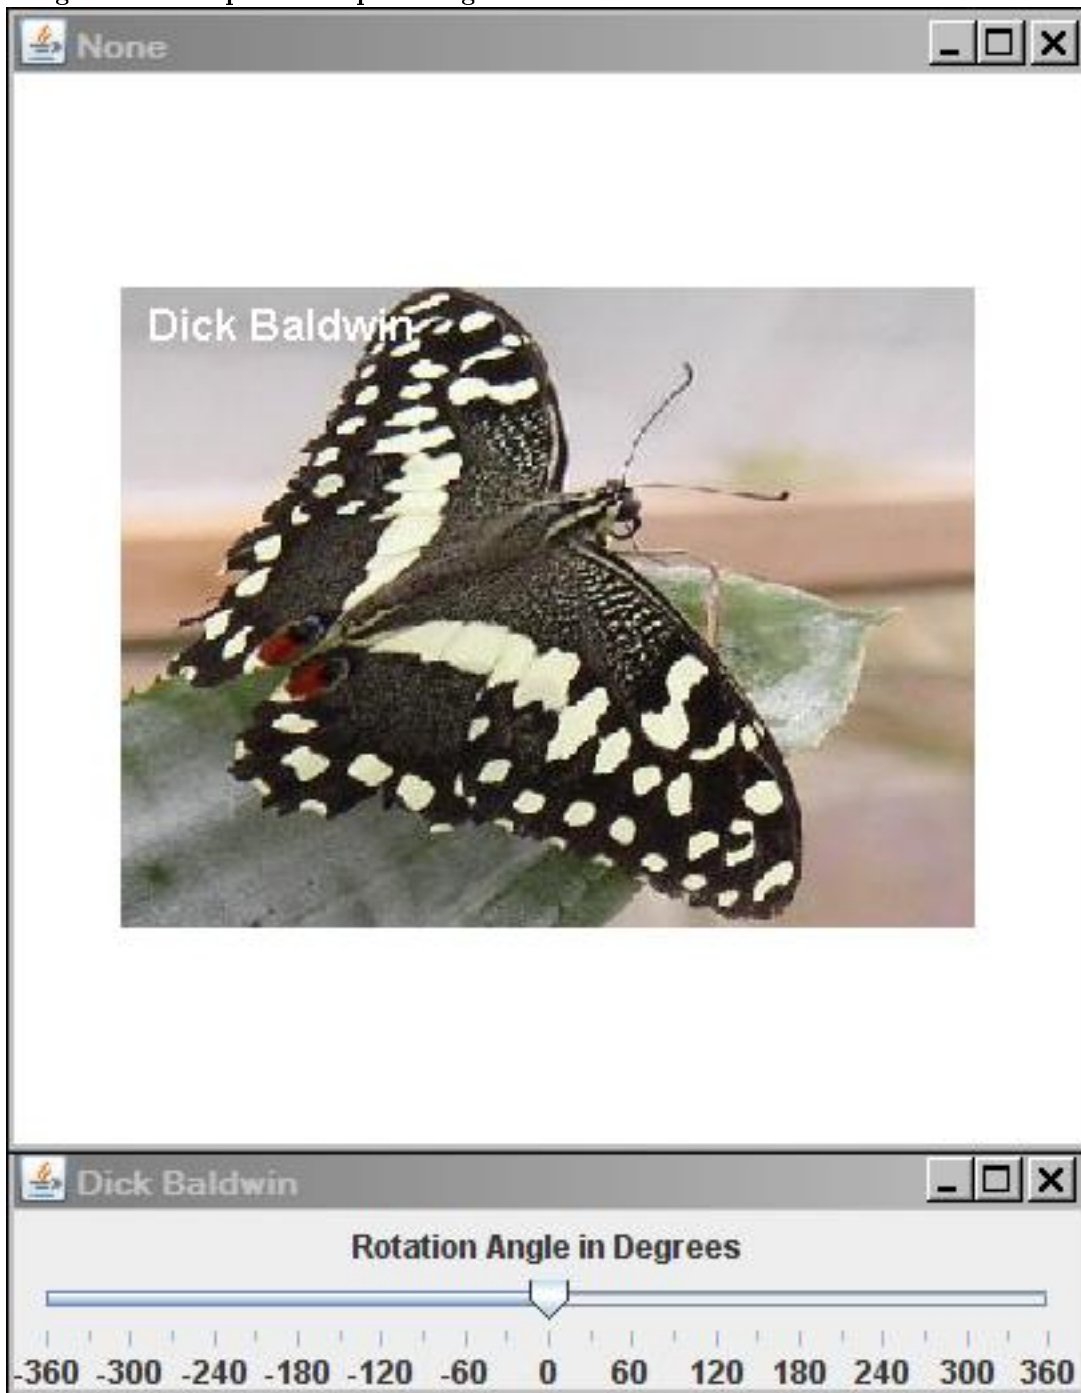

Figure 9 - Required output image for Prob05.

1. Click the download link for the zip files that contain input image files and solution source code files. Use the capabilities of your browser to download and save the contents of those zip files.
2. If necessary, replace calls to the `show` method in my source code with calls to the `explore` method to force the program to display the output images in a **PictureExplorer** window.
3. Compile and run the source code.
4. Write, compile, and run a simple Java program that will display each input image file in a **PictureExplorer** window.
5. Use the input and output **PictureExplorer** windows to compare the input and output color values on a pixel by pixel basis.

You may find other useful hints in my online tutorials and slides for this course.

4.4.3.4.3.1.6 Testing Your Programs

You can compile and execute your program by following the instructions given at Java OOP: The Guzdial-Ericson Multimedia Class Library ⁴⁶⁸ .

4.4.3.4.3.1.7 Program Specifications

4.4.3.4.3.1.7.1 Program 1

Listing 1 - Write the Java application described below.

```
/*File Prob01 Copyright 2012 R.G.Baldwin
```

Write a program named Prob01 that uses Ericson's media library along with the image file named Prob01a.jpg to produce the graphic output image shown in Figure 1 (p. 1945) below.

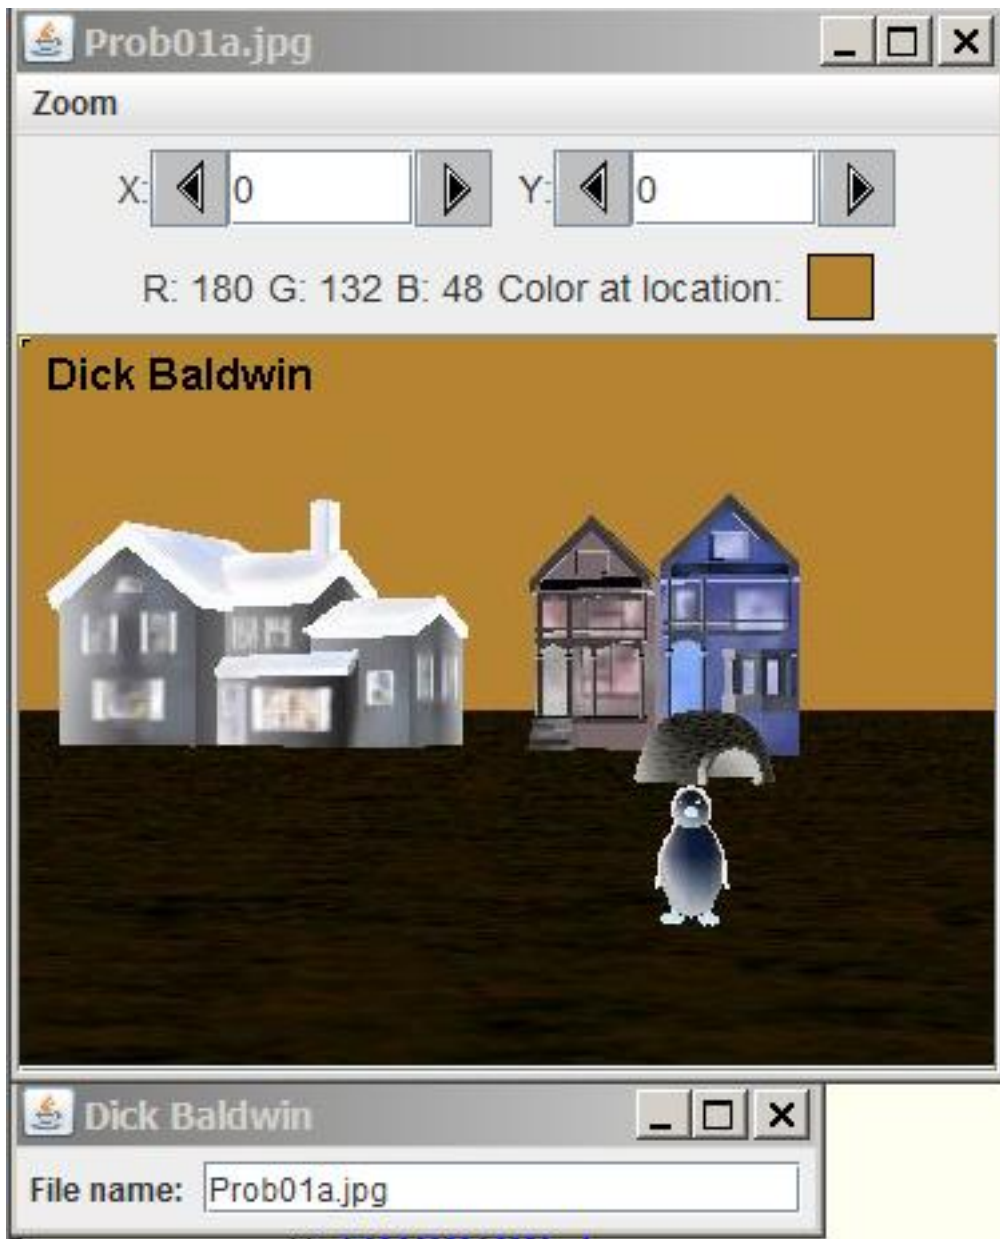

Click here ⁴⁶⁹ to download a zip file containing the required image file along with the source code for a solution.

When the program first starts running, only the GUI containing the text field is visible. When you type the file name into the text field and press Enter, the image of the penguin appears and the GUI moves to a position below the image of the penguin. The program terminates and returns control to the operating system when you click the X in the upper-right corner of the GUI.

Figure 1 - Required output images for Prob01.

⁴⁶⁸<http://cnx.org/content/m44148/latest/>

⁴⁶⁹<http://cnx.org/content/m44262/latest/Prob01solution.zip>

4.4.3.4.3.1.7.2 Program 2

Listing 2 - Write the Java application described below.

```
/*File Prob02 Copyright 2012 R.G.Baldwin
```

Write a program named Prob02 that uses Ericson's media library along with the image file named Prob02.jpg to produce the graphic output images shown in Figure 2 (p. 1947) below.

Click here ⁴⁷⁰ to download a zip file containing the required image file along with the source code for a solution.

Whenever you click the button in the GUI in the lower image, the green color component value at the location of the crosshair cursor in the upper image is displayed in the text field in the GUI.

⁴⁷⁰<http://cnx.org/content/m44262/latest/Prob02solution.zip>

Figure 2 - Required output images for Prob02.

4.4.3.4.3.1.7.3 Program 3

Listing 3 - Write the Java application described below.

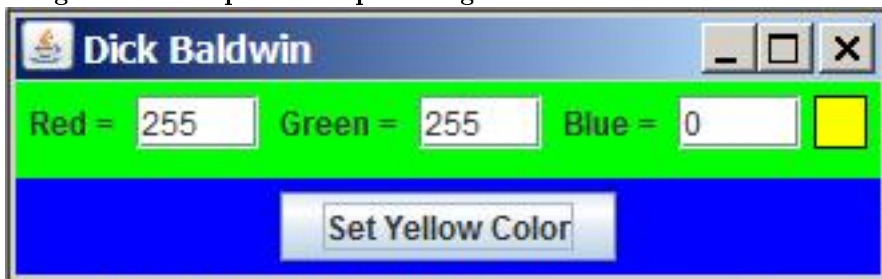

```
/*File Prob03 Copyright 2012 R.G.Baldwin
```

Write a program named Prob03 that uses Ericson's media library to produce the graphic output image shown in Figure 3 (p. 1948) below.

Click here ⁴⁷¹ to download a zip file containing the source code for a solution.

Whenever you click the button in the GUI, the square in the upper right turns from black to yellow with a black border and the RGB color values for the color yellow appear in the three text fields.

Figure 3 - Required output image for Prob03.

4.4.3.4.3.1.7.4 Program 4

Listing 4 - Write the Java application described below.

```
/*File Prob04 Copyright 2012 R.G.Baldwin
```

Write a program named Prob04 that uses Ericson's media library to produce the graphic output images shown in Figure 4 (p. 1948) below.

Click here ⁴⁷² to download a zip file containing the source code for a solution.

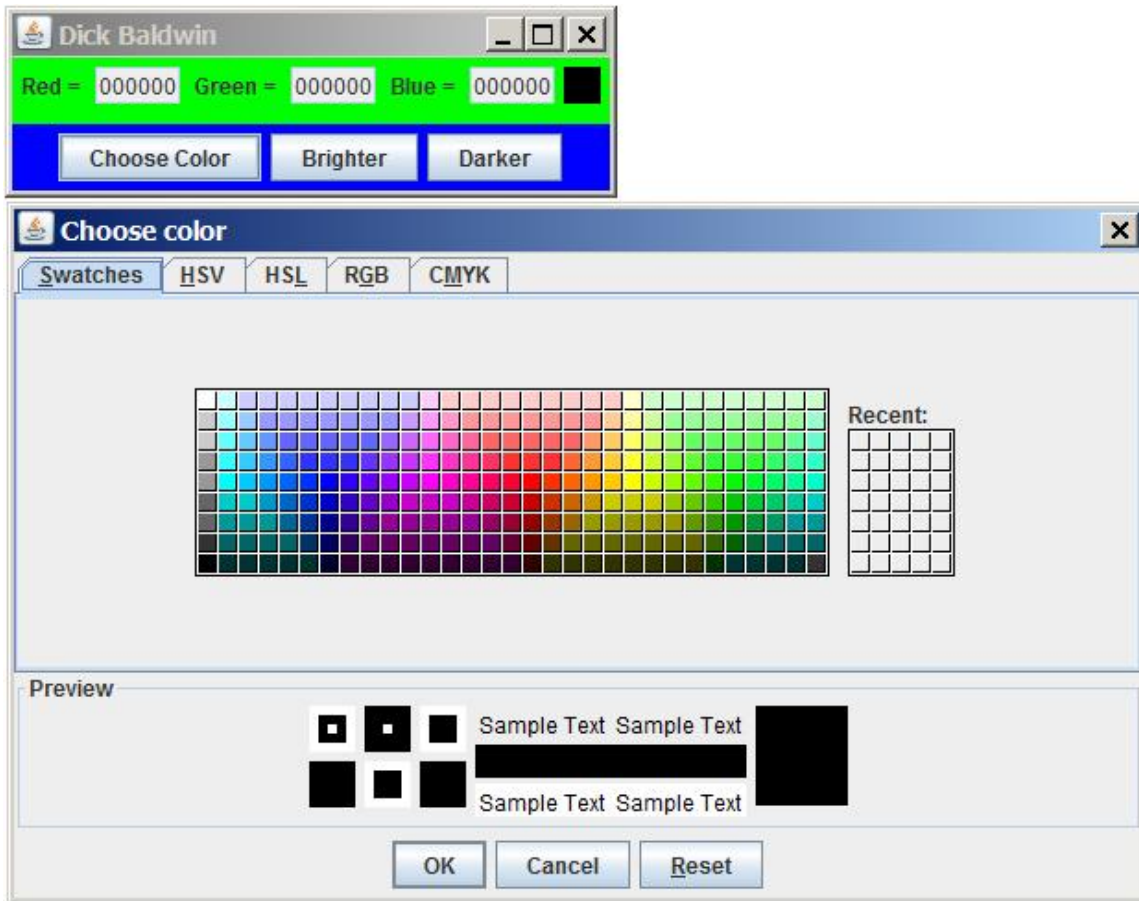

Whenever you click the "Choose Color" button in the GUI in the upper image, the color chooser dialog shown in the lower image appears. When you select a color and click the OK button, the color chooser dialog disappears and that color appears in the square in the upper right portion of the GUI. In addition, the red, green, and blue color component values for that color appear in the corresponding text fields.

Whenever you click the "Brighter" and "Darker" buttons, the color displayed in the square becomes brighter or darker and the color values in the text fields change accordingly.

Figure 4 - Required output images for Prob04.

⁴⁷¹<http://cnx.org/content/m44262/latest/Prob03solution.zip>

⁴⁷²<http://cnx.org/content/m44262/latest/Prob04solution.zip>

4.4.3.4.3.1.7.5 Program 5

Listing 5 - Write the Java application described below.

```
/*File Prob05 Copyright 2012 R.G.Baldwin
```

Write a program named Prob05 that uses Ericson's media library along with the image file named Prob05.jpg to produce the graphic output images shown in Figure 5 (p. 1949) below.

Click here ⁴⁷³ to download a zip file containing the required image file along with the source code for a solution.

The color in the square in the upper right of the GUI in the lower image is governed by the color values in the red, green, and blue text fields.

Whenever you click the button in the GUI, the pixel at the crosshair cursor in the upper image is changed to reflect the color in the square in the GUI. This can best be seen when the upper image is zoomed to 500%.

Figure 5 - Required output image for Prob05.

4.4.4 Review Event Handling

4.4.4.1 Jy0037: Review Event Handling⁴⁷⁴**4.4.4.1.1 Table of Contents**

- Preface (p. 1953)
- Questions (p. 1953)
 - 1 (p. 1953) , 2 (p. 1953) , 3 (p. 1953) , 4 (p. 1954) , 5 (p. 1954) , 6 (p. 1954) , 7 (p. 1954) , 8 (p. 1954) , 9 (p. 1954) , 10 (p. 1954) , 11 (p. 1954) , 12 (p. 1954) , 13 (p. 1955) , 14 (p. 1955) , 15 (p. 1955) , 16 (p. 1955) , 17 (p. 1957) , 18 (p. 1958) , 19 (p. 1958) , 20 (p. 1959) , 21 (p. 1960) , 22 (p. 1961) , 23 (p. 1961) , 24 (p. 1963) , 25 (p. 1964) , 26 (p. 1965) , 27 (p. 1965) , 28 (p. 1965) , 29 (p. 1966) , 30 (p. 1968) , 31 (p. 1969) , 32 (p. 1970) , 33 (p. 1971) , 34 (p. 1973) , 35 (p. 1974) , 36 (p. 1975) , 37 (p. 1976)
- Listings (p. 1978)
- Answers (p. 1980)
- Miscellaneous (p. 1984)

4.4.4.1.2 Preface

This module contains a non-exhaustive set of review questions and answers keyed to the material in the Event Handling sub-collection. The questions are heavily weighted toward the tutorials listed in Jy0035: Java OOP: Preface to Event Handling⁴⁷⁵ and the seven modules that begin with Java OOP: The AWT and Swing, A Preview⁴⁷⁶ in the sub-collection titled **Essence of OOP** .

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

These questions are similar to many of the questions on the online Blackboard test for Event Handling in ITSE 2317. When you take the test in the testing center, you will only have access to the computer screen, a pencil, and a sheet of scratch paper. You might benefit by limiting yourself to only those tools as you study this material to get used to working under those limitations.

4.4.4.1.3 Questions**4.4.4.1.3.1 Question 1** .

True or False: AWT is the abbreviation for *Abstract Windows Toolkit* .

Answer 1 (p. 1984)

4.4.4.1.3.2 Question 2

True or False: GUI is the abbreviation for the Graphical User Interface.

Answer 2 (p. 1984)

4.4.4.1.3.3 Question 3

True or False: There are two primary packages that are used for **GUI** programming in Java SE 7.

- java.awt.*
- com.sun.java.swing.*

Answer 3 (p. 1983)

⁴⁷⁴This content is available online at <<http://cnx.org/content/m47927/1.6/>>.

⁴⁷⁵<http://cnx.org/content/m47842/latest/?collection=col11441/latest>

⁴⁷⁶<http://cnx.org/content/m44331/latest/?collection=col11441/latest>

4.4.4.1.3.4 Question 4

True or False: When it was released, Swing was a replacement for the AWT.

Answer 4 (p. 1983)

4.4.4.1.3.5 Question 5

True or False: A *callback* mechanism is a mechanism where a method in one object asks a method in another object to *"call me back"* or *"notify me"* when an interesting event happens.

Answer 5 (p. 1983)

4.4.4.1.3.6 Question 6

True or False: Many different objects may ask one object to notify them when the interesting event happens. This is sometimes referred to as *unicasting* .

Answer 6 (p. 1983)

4.4.4.1.3.7 Question 7

True or False: API is an abbreviation for Application Programming Interface.

Answer 7 (p. 1983)

4.4.4.1.3.8 Question 8

Given: The event model that has been in use since Java version 1.1 is sometimes called the Delegation Event Model and is sometimes called the JavaBeans Event Model. (*It may be called by other names as well.*) Although there was an earlier model, the Delegation Event Model is the event model to which the questions in this review module apply.

True or False: The event model makes use of **event sources** and **event listeners** .

Answer 8 (p. 1983)

4.4.4.1.3.9 Question 9

True or False: An event **listener** is an object that has the ability to determine when an interesting event has occurred, and to notify **source** objects of the occurrence of the event.

Answer 9 (p. 1983)

4.4.4.1.3.10 Question 10

True or False: A **listener** object is an instance of a class (or instance of a subclass of a class) that implements a specific *listener interface* .

Answer 10 (p. 1983)

4.4.4.1.3.11 Question 11

True or False: A number of listener interfaces are defined where each interface declares the methods appropriate for a specific class of events. Thus, there is natural pairing of classes of events and interface definitions.

Answer 11 (p. 1983)

4.4.4.1.3.12 Question 12

True or False: There is a class of mouse events that includes most of the events normally associated with mouse action and there is a matching source definition that is used to define a listener class for those events.

Answer 12 (p. 1983)

4.4.4.1.3.13 Question 13

True or False: A listener object can be registered on a source object to be notified of the occurrence of all events of the specific class for which the listener object is designed.

Answer 13 (p. 1982)

4.4.4.1.3.14 Question 14

True or False: Once a listener object is registered to be notified of all events of the specific class for which the listener object is designed, the occurrence of such an event will automatically invoke the matching method in the listener object. The code in the body of the method is designed by the programmer to perform the desired action when the event occurs.

Answer 14 (p. 1982)

4.4.4.1.3.15 Question 15

True or False: In many cases, the same goal can be achieved by either implementing a listener interface or extending a corresponding adapter class.

Answer 15 (p. 1982)

4.4.4.1.3.16 Question 16

True or False: The program shown below will compile and run successfully. When it starts running, it displays a small window and also displays the following on the command-line screen:

WProcl windowActivated test msg

WProcl windowOpened test msg

Whenever the small window loses the focus, the following is displayed on the command-line screen:

WProcl windowDeactivated test msg

Whenever the small window gains the focus, the following is displayed on the command-line screen:

WProcl windowActivated test msg

Whenever the user clicks the X-button, the small window disappears and the following is displayed on the command-line screen.

WProcl windowClosing test msg

WProcl windowDeactivated test msg

WProcl windowClosed test msg

Listing 1 . Question 16.

```

/*File Q16.java
*****/
import java.awt.*;
import java.awt.event.*;

public class Q16 {
    public static void main(String[] args){
        GUI gui = new GUI();//instantiate a GUIInterface object
    }//end main
} //end class Q16
//=====//

class GUI{
    public GUI(){//constructor
        //Create a new Frame object

```

```

    Frame displayWindow = new Frame();
    displayWindow.setSize(300,200);
    displayWindow.setTitle("Q16");

    WProc1 winProcCmd1 = new WProc1(displayWindow);
    displayWindow.addWindowListener(winProcCmd1);
    displayWindow.setVisible(true);
} //end constructor
} //end class GUI definition
//=====//

class WProc1 implements WindowListener{
    Frame displayWindowRef;

    WProc1(Frame windowIn){ //constructor
        this.displayWindowRef = windowIn;
    } //end constructor

    public void windowClosed(WindowEvent e){
        System.out.println("WProc1 windowClosed test msg");
    } //end windowClosed()

    public void windowIconified(WindowEvent e){
        System.out.println("WProc1 windowIconified test msg");
    } //end windowIconified()

    public void windowOpened(WindowEvent e){
        System.out.println("WProc1 windowOpened test msg");
    } //end windowOpened()

    public void windowClosing(WindowEvent e){
        System.out.println("WProc1 windowClosing test msg");
        displayWindowRef.dispose(); //generate WindowClosed
    } //end windowClosing()

    public void windowDeiconified(WindowEvent e){
        System.out.println(
            "WProc1 windowDeiconified test msg");
    } //end windowDeiconified()

    public void windowActivated(WindowEvent e){
        System.out.println("WProc1 windowActivated test msg");
    } //end windowActivated()

    public void windowDeactivated(WindowEvent e){
        System.out.println(
            "WProc1 windowDeactivated test msg");
    } //end windowDeactivated()
} //end class WProc1
//=====//

```

Answer 16 (p. 1982)

4.4.4.1.3.17 Question 17

True or False: The program shown below will compile and run successfully. When it starts running, it displays a small window and doesn't display anything on the command-line screen.

Whenever the small window is iconified to the system tray, the following is displayed on the command-line screen:

```
***** WProc2 windowIconified test msg
```

Whenever the small window is deiconified from the system tray, the following is displayed on the command-line screen:

```
***** WProc2 windowDeiconified test msg
```

Nothing happens when the user clicks the X-button. The program does not terminate and does not return control to the operating system.

Listing 2 . Question 17.

```
/*File Q17.java Copyright 1997, R.G.Baldwin
*****/

import java.awt.*;
import java.awt.event.*;

public class Q17 {
    public static void main(String[] args){
        GUI gui = new GUI();//instantiate a GUIInterface object
    }//end main
} //end class Q17
//=====//

class GUI{
    public GUI(){//constructor
        //Create a new Frame object
        Frame displayWindow = new Frame();
        displayWindow.setSize(300,200);
        displayWindow.setTitle("Q17");

        WProc2 winProcCmd2 = new WProc2();
        displayWindow.addWindowListener(winProcCmd2);
        displayWindow.setVisible(true);

    } //end constructor
} //end class GUI definition
//=====//

class WProc2 extends WindowAdapter{

    public void windowIconified(WindowEvent e){
        System.out.println(
            "***** WProc2 windowIconified test msg");
    } //end windowIconified()

    public void windowDeiconified(WindowEvent e){
        System.out.println(
```

```

        "***** WProc2 windowDeiconified test msg");
    }//end windowDeiconified()

} //end class WProc2

```

Answer 17 (p. 1982)

4.4.4.1.3.18 Question 18

True or False: The default layout manager for a Frame object is **FlowLayout** .

Answer 18 (p. 1982)

4.4.4.1.3.19 Question 19

True or False: The program shown below displays a small Frame object on the computer screen. When the user clicks the mouse inside the Frame object, the mouse coordinates are displayed near the mouse pointer.

When the user clicks the X-button in the upper right corner of the Frame, the program terminates and returns control to the operating system.

Listing 3 . Question 19.

```

/*File Q19.java
*/
import java.awt.*;
import java.awt.event.*;

public class Q19 {
    public static void main(String[] args){
        GUI gui = new GUI();
    } //end main
} //end class Q19
//-----

class MyFrame extends Frame{
    int clickX;
    int clickY;

    public void paint(Graphics g){
        g.drawString(
            "" + clickX + ", " + clickY, clickX, clickY);
    } //end paint()
} //end class MyFrame
//-----

class GUI {
    public GUI(){ //constructor
        MyFrame displayWindow = new MyFrame();
        displayWindow.setSize(300,300);
        displayWindow.setTitle("Q19");
        displayWindow.setVisible(true);

        displayWindow.addWindowListener(new WProc1());
        displayWindow.addMouseListener(

```

```

        new MProc1(displayWindow));
    }//end constructor
} //end class GUI definition
//-----

class MProc1 extends MouseAdapter{
    MyFrame refToWin; //save a reference to the window here

    MProc1(MyFrame inWin){//constructor
        refToWin = inWin;//save ref to window
    }//end constructor

    public void mousePressed(MouseEvent e){
        refToWin.clickX = e.getX();
        refToWin.clickY = e.getY();
        refToWin.repaint();
    }//end mousePressed()
} //end class MProc1
//-----
class WProc1 extends WindowAdapter{
    public void windowClosed(WindowEvent e){
        System.exit(0);
    }//end windowClosed()
} //end class Wproc1

```

Answer 19 (p. 1982)

4.4.4.1.3.20 Question 20

True or False: The program shown below will compile and run successfully. When it starts running, it displays a small JFrame window and doesn't display anything on the command-line screen.

Whenever the small window is iconified to the system tray, the following is displayed on the command-line screen:

```
***** WProc2 windowIconified test msg
```

Whenever the small window is deiconified from the system tray, the following is displayed on the command-line screen:

```
***** WProc2 windowDeiconified test msg
```

When the user clicks the X-button, the program terminates and returns control to the operating system.

Listing 4 . Question 20.

```

/*File Q20.java
*****/

import java.awt.*;
import java.awt.event.*;
import javax.swing.*;

public class Q20 {
    public static void main(String[] args){
        GUI gui = new GUI();//instantiate a GUIInterface object
    } //end main
} //end class Q20

```

```
//=====//

class GUI{
    public GUI(){//constructor
        JFrame displayWindow = new JFrame();
        displayWindow.setSize(300,200);
        displayWindow.setTitle("Q20");
        //Following is available in recent Java versions
        displayWindow.setDefaultCloseOperation(
            JFrame.EXIT_ON_CLOSE);
        displayWindow.addWindowListener(new WProc2());
        displayWindow.setVisible(true);

    }//end constructor
}//end class GUI definition
//=====//

class WProc2 extends WindowAdapter{
    public void windowIconified(WindowEvent e){
        System.out.println(
            "***** WProc2 windowIconified test msg");
    }//end windowIconified()

    public void windowDeiconified(WindowEvent e){
        System.out.println(
            "***** WProc2 windowDeiconified test msg");
    }//end windowDeiconified()
}//end class WProc2
//=====//
```

Answer 20 (p. 1982)

4.4.4.1.3.21 Question 21

True or False: The program shown below displays a small JFrame object on the computer screen. When the user clicks the mouse inside the JFrame object, the mouse coordinates are displayed near the mouse pointer. Old coordinates are erased and new coordinates are displayed with each successive mouse click.

When the user clicks the X-button in the upper right corner of the Frame, the program terminates and returns control to the operating system.

Listing 5 . Question 21.

```
/*File Q21.java
*****/
import java.awt.*;
import java.awt.event.*;
import javax.swing.*;
public class Q21 {
    public static void main(String[] args){
        GUI gui = new GUI();//instantiate a GUI
    }//end main
}//end class Q21
//=====//
```

```

class MyFrame extends JFrame{
    int clickX;
    int clickY;

    public void paint(Graphics g){
        g.drawString(
            "" + clickX + ", " + clickY, clickX, clickY);
    }//end paint()
}//end class MyFrame
//=====//

class GUI {
    public GUI(){//constructor
        MyFrame displayWindow = new MyFrame();
        displayWindow.setSize(300,300);
        displayWindow.setTitle("Q21");
        displayWindow.setVisible(true);
        displayWindow.setDefaultCloseOperation(
            JFrame.EXIT_ON_CLOSE);

        displayWindow.addMouseListener(
            new MouseProc(displayWindow));
    }//end constructor
}//end class GUI definition
//=====//

class MouseProc extends MouseAdapter{
    MyFrame refToWin; //save a reference to the source here

    MouseProc(MyFrame inWin){//constructor
        refToWin = inWin;//save ref to window
    }//end constructor

    public void mousePressed(MouseEvent e){
        refToWin.clickX = e.getX();

        refToWin.clickY = e.getY();
        refToWin.repaint();
    }//end mousePressed()
}//end class MouseProc
//=====//

```

Answer 21 (p. 1982)

4.4.4.1.3.22 Question 22

True or False: There must always be a one-to-one correspondence between source objects and listener objects.

Answer 22 (p. 1981)

4.4.4.1.3.23 Question 23

True or False: The program shown below displays two small Frame objects side-by-side on the computer screen. Clicking inside either Frame object causes the mouse coordinates to be displayed in that Frame

object relative to the upper-left corner of the Frame object.

Clicking the X-button on either Frame object causes that Frame object to disappear from the computer screen. Clicking the X-button on both Frame objects causes both Frame objects to disappear and causes the program to terminate returning control to the operating system.

Listing 6 . Question 23.

```

/*File Q23.java
*/
//=====================================================//

import java.awt.*;
import java.awt.event.*;

public class Q23 {
    public static void main(String[] args){
        GUI gui = new GUI();
    }//end main
}//end class Q23
//=====================================================//

class MyFrame extends Frame{
    int xCoord;
    int yCoord;

    MyFrame(){//constructor
        setTitle("Q3");
        setSize(200,200);
    }//end constructor

    public void paint(Graphics g){
        g.drawString("" + xCoord + ", " + yCoord, xCoord, yCoord);
    }//end paint()
}//end class MyFrame
//=====================================================//

class GUI {
    public GUI(){//constructor

        MyFrame myFrame1 = new MyFrame();
        myFrame1.setVisible(true);

        MyFrame myFrame2 = new MyFrame();
        myFrame2.setLocation(201,0);
        myFrame2.setVisible(true);

        WProc1 winProcCmd1 = new WProc1();
        myFrame1.addWindowListener(winProcCmd1);
        myFrame2.addWindowListener(winProcCmd1);

        MouseProc mouseProcCmd = new MouseProc();
        myFrame1.addMouseListener(mouseProcCmd);

```

```

        myFrame2.addMouseListener(mouseProcCmd);
    }//end constructor
} //end class GUI definition
//=====//

class MouseProc extends MouseAdapter{
    public void mousePressed(MouseEvent e){
        ((MyFrame)e.getComponent()).xCoor = e.getX();
        ((MyFrame)e.getSource()).yCoor = e.getY();
        e.getComponent().repaint();
    } //end mousePressed()
} //end class MouseProc
//=====//

class WProc1 extends WindowAdapter{
    public void windowClosing(WindowEvent e){
        System.exit(0);
    } //end windowClosing()
} //end class WProc1
//=====//

```

Answer 23 (p. 1981)

4.4.4.1.3.24 Question 24

True or False: The program shown below displays a small JFrame with a red background. Two overlapping buttons appear in front of the red background. One button is green and the other button is yellow.

At startup, the green button is in front of and partially hides the yellow button. If you click the front most button, the two buttons swap positions front to back. In other words, clicking the green button when it is in front brings the yellow button to the front. Clicking the yellow button when it is in front brings the green button to the front. Clicking the button in the back does not cause the buttons to swap positions.

Clicking the X-button causes the program to terminate and return control to the operating system.

Listing 7 . Question 24.

```

/*File Q24
*****/

import java.awt.*;
import java.awt.event.*;
import javax.swing.*;

class Q24 extends JFrame{//subclass JFrame
    JLayeredPane theLayeredPane;
    JButton greenButton;

```

Answer 24 (p. 1981)

4.4.4.1.3.25 Question 25

True or False: The `MouseEvent` interface declares three methods:

- public abstract void mouseDragged(MouseEvent e)
- public abstract void mouseMoved(MouseEvent e)
- public abstract void mousePressed(MouseEvent e)

Answer 25 (p. 1981)

4.4.4.1.3.26 Question 26

True or False: The `mouseDragged` method is invoked when a mouse button is pressed on a component and then dragged.

Answer 26 (p. 1981)

4.4.4.1.3.27 Question 27

True or False: The `mouseMoved` method is invoked when the mouse is moved on a component with no buttons down.

Answer 27 (p. 1981)

4.4.4.1.3.28 Question 28

True or False: This program displays a small Frame object on the computer screen. When you hold down a mouse button and move your mouse pointer into the client area of the Frame, the coordinates of the mouse pointer appear directly above the pointer. As you move the mouse pointer around in the client area while holding the button down, the coordinates of the pointer continue to be displayed above the pointer.

If you release the mouse button while moving the mouse in the client area, the coordinates of the point where you released the button appear and remain there until you press the mouse button, at which time the coordinates of the mouse pointer resume being displayed.

Clicking the X-button terminates the program and returns control to the operating system.

Answer 28 (p. 1981)

4.4.4.1.3.29 Question 29

True or False: The program shown below displays a Frame object on the computer screen. The Frame object contains a single large Button object labeled Whistle.

When the user clicks the Whistle button, the program displays the following text on the command-line screen.

I am whistling, Tweet Tweet Tweet

When the user clicks the X-button, the program terminates returning control to the operating system.

Listing 9 . Question 29.

```

/*File Q29.java Copyright 1997, R.G.Baldwin
*****
import java.awt.*;
import java.awt.event.*;

public class Q29 {
    void whistle() {System.out.println(
        "I am whistling, Tweet Tweet Tweet");}
    //-----

    static public void main(String[] args){
        Q29 app = new Q29();
        GUI gui = app.new GUI();
    }//end main()
    //-----

    //The GUI class is defined inside the Q29 class and is
    // an inner-class of Q29.
    class GUI extends Frame{

} //end GUI constructor
} //end class GUI
} //end class Q29
//=====

```

Answer 29 (p. 1980)

4.4.4.1.3.30 Question 30

True or False: The program shown below displays a small Frame object with a white background. A Button object and a Label object are placed in the Frame. The Label is on the left and the Button is on the right. The two are lined up horizontally and the pair is centered left-to-right in the Frame.

The Button is labeled "Button" and the Label is labeled "Initial Text".

When you click the Button, the text in the Label changes to "Ouch".

When you click the X-button, the program terminates and returns control to the operating system.

Listing 10 . Question 30.

```

/*File Q30.java
*****
import java.awt.*;
import java.awt.event.*;

public class Q30 extends Frame {
    Label myLabel;
    //-----//
    static public void main(String[] args){
        Q30 app = new Q30();
    } //end main()
    //-----//

    public Q30(){//constructor
        this.setTitle("Q30");
        this.setLayout(new FlowLayout());
        Button myButton;
        this.add(myButton = new Button("Button"));
        this.add(myLabel = new Label("Initial Text"));
        //-----//

        myButton.addActionListener(
            new //instantiate anonymous object of the class
              ActionListener(){//anonymous class definition
                public void actionPerformed(ActionEvent e){
                    myLabel.setText("Ouch");
                } //end actionPerformed()
            } //end ActionListener class definition

```

```

    );//end addActionListener() statement

    this.addWindowListener(
        new WindowAdapter(){//anonymous class definition
            public void windowClosing(WindowEvent e){
                System.exit(0);//terminate the program
            }//end windowClosing()
        }//end WindowAdapter
    );//end addWindowListener
//-----

    this.setSize(300,100);
    this.setVisible(true);
} //end Q30 constructor
} //end class Q30
//=====

```

Answer 30 (p. 1980)

4.4.4.1.3.31 Question 31

True or False: The program shown below displays a JSlider centered in a JFrame. The JSlider is calibrated to extend from -100 on the left end to 100 on the right end with 0 at the center. There is a tick mark every 10 units and every other tick mark is labeled, including -100, 0, and 100.

When you move the thumb on the slider, the value of the current position of the thumb is displayed on the command-line screen. Old values are not erased when a new value is displayed.

When you click the X-button, the program terminates and returns control to the operating system.

Listing 11 . Question 31.

```

/*File Q31
*****
import javax.swing.JFrame;
import javax.swing.JSlider;
import javax.swing.event.ChangeListener;
import javax.swing.event.ChangeEvent;
import java.awt.BorderLayout;
public class Q31{

    public static void main(String[] args){
        new Q31gui();
    } //end main method
} //end class Q31
//=====//

class Q31gui extends JFrame{

    private JSlider slider = new JSlider(-100,100);

    public Q31gui(){//constructor
        setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);

        slider.setMajorTickSpacing(20);

```

```

slider.setMinorTickSpacing(10);
slider.setPaintTicks(true);
slider.setPaintLabels(true);

getContentPane().add(slider);

setSize(300,100);
setTitle("Q31");
setVisible(true);
//-----//

slider.addChangeListener(
    new ChangeListener(){
        public void stateChanged(ChangeEvent e){
            System.out.print(" " + slider.getValue());
        }//end stateChanged
    }//end new ChangeListener
);//end addChangeListener
//-----//
}//end constructor
//-----//

}//end class Q31gui

```

Answer 31 (p. 1980)

4.4.4.1.3.32 Question 32

True or False: The program shown below displays a small JFrame object on the computer screen. Each time the user clicks the mouse inside the JFrame object, the mouse coordinates are displayed near the mouse pointer and the old mouse coordinates from the previous click are erased.

When the user clicks the X-button in the upper right corner of the Frame, the program terminates and returns control to the operating system.

Listing 12 . Question 32.

```

/*File Q32.java Copyright 2002 R.G.Baldwin
*****/

import java.awt.*;
import java.awt.event.*;
import javax.swing.*;

public class Q32 {
    public static void main(String[] args){
        new Q32gui();
    }//end main
}//end class Q32
//=====//

class Q32gui {
    public Q32gui(){//constructor
        JFrame theFrame = new JFrame();

```

```

    theFrame.setSize(200,200);
    theFrame.setTitle("Q32");
    DisplaySpace displayWindow = new DisplaySpace();

    theFrame.getContentPane().add(displayWindow,"Center");
    theFrame.setDefaultCloseOperation(
                                JFrame.EXIT_ON_CLOSE);
    theFrame.setVisible(true);

    displayWindow.addMouseListener(
                                new MProc1(displayWindow));
} //end constructor
//=====//

class DisplaySpace extends JPanel{

    int clickX;
    int clickY;

    public void paintComponent(Graphics g){
        super.paintComponent(g);
        g.drawString(
            "" + clickX + ", " + clickY, clickX, clickY);
    } //end paintComponent
} //end class DisplaySpace
//=====//

class MProc1 extends MouseAdapter{
    DisplaySpace refToWin;

    MProc1(DisplaySpace inWin){ //constructor
        refToWin = inWin; //save ref to window
    } //end constructor

    public void mousePressed(MouseEvent e){
        refToWin.clickX = e.getX();
        refToWin.clickY = e.getY();
        refToWin.repaint(); //display coordinate information
    } //end mousePressed()
} //end class MProc1
} //end GUI class
//=====//

```

Answer 32 (p. 1980)

4.4.4.1.3.33 Question 33

True or False: The program shown below displays a small JFrame object on the computer screen. Each time the user clicks the mouse inside the JFrame object, the mouse coordinates are displayed near the mouse pointer and the old mouse coordinates from the previous click are erased.

When the user clicks the X-button in the upper right corner of the Frame, the program terminates and returns control to the operating system.

Listing 13 . Question 33.

```

/*File Q33.java
*****/

import java.awt.*;
import java.awt.event.*;
import javax.swing.*;

public class Q33 {
    public static void main(String[] args){
        new Q33gui();
    }//end main
} //end class Q33
//=====//

class Q33gui extends JFrame{
    public Q33gui(){//constructor
        setSize(200,200);
        setTitle("Q33");
        getContentPane().add(new DisplaySpace(),"Center");
        setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
        setVisible(true);
    }//end constructor
} //end Q33gui
//=====//

class DisplaySpace extends JPanel{

    g.drawString(
        "" + clickX + ", " + clickY, clickX, clickY);
} //end paint

} //end class GUI
//-----//
```

Answer 34 (p. 1980)

4.4.4.1.3.35 Question 35

True or False: The program shown below displays a small JFrame object on the computer screen.

When you move your mouse pointer around inside the client area of the frame, without pressing either mouse button, the coordinates of the mouse pointer appear directly above the pointer. In this case, the coordinates are displayed using black characters.

When you move your mouse pointer around inside the client area of the frame, while pressing either mouse button, the coordinates of the mouse pointer appear directly above the pointer. In this case, the coordinates are displayed using red characters.

When you click X-button in the upper right corner of the frame, the program terminates and control is returned to the operating system.

Listing 15 . Question 35.

```
/*File Q35.java
*****/

import java.awt.*;

//=====//

```

Answer 35 (p. 1980)

4.4.4.1.3.36 Question 36

True or False: The program shown below displays a small JFrame object containing two JButton objects and a JLabel object. The JLabel has a green background and blue letters. The captions on the two JButton objects are Top and Bottom.

The three objects are displayed vertically in the JFrame. The Top JButton appears at the top of the column of objects. The Bottom JButton appears at the bottom of the column. The JLabel appears between the two JButton objects.

At startup, the JLabel displays the word Top. When you click the Bottom button, the word in the JLabel changes to Bottom. When you click the Top button, the word in the JLabel changes to Top. When you click X-button on the JFrame, the program terminates and returns control to the operating system.

//-----//

public void actionPerformed(ActionEvent e){
    if(e.getActionCommand().indexOf("Top") != -1)
        label.setText("Top");
    else
        label.setText("Bottom");
} //end actionPerformed()

} //end class Q37gui
//=====//

```

Answer 37 (p. 1980)

4.4.4.1.4 Listings

- Listing 1 (p. 1955) . Question 16.
- Listing 2 (p. 1957) . Question 17.
- Listing 3 (p. 1958) . Question 19.
- Listing 4 (p. 1959) . Question 20.
- Listing 5 (p. 1960) . Question 21.
- Listing 6 (p. 1962) . Question 23.
- Listing 7 (p. 1963) . Question 24.
- Listing 8 (p. 1965) . Question 28.
- Listing 9 (p. 1967) . Question 29.
- Listing 10 (p. 1968) . Question 30.
- Listing 11 (p. 1969) . Question 31.
- Listing 12 (p. 1970) . Question 32.
- Listing 13 (p. 1972) . Question 33.
- Listing 14 (p. 1973) . Question 34.
- Listing 15 (p. 1974) . Question 35.
- Listing 16 (p. 1975) . Question 36.
- Listing 17 (p. 1977) . Question 37.

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the computer screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

4.4.4.1.5 Answers

4.4.4.1.5.1 Answer 37

True. Note that the GUI object is both a source of action events and a listener for action events fired by the buttons.

Back to Question 37 (p. 1976)

4.4.4.1.5.2 Answer 36

True. Note that the GUI object is both a source of action events and a listener for action events fired by the buttons.

Back to Question 36 (p. 1975)

4.4.4.1.5.3 Answer 35

False. The red and black colors are reversed. Otherwise, the statement would be true.

Back to Question 35 (p. 1974)

4.4.4.1.5.4 Answer 34

True. This program uses anonymous inner classes to define and instantiate a mouse event handler and a window event handler.

Back to Question 34 (p. 1973)

4.4.4.1.5.5 Answer 33

False. The code in the anonymous mouse event handler class calls a method named `onMouseEvent`. It should call a method named `mousePressed` instead, in which case the program would behave as described.

Back to Question 33 (p. 1971)

4.4.4.1.5.6 Answer 32

True.

Back to Question 32 (p. 1970)

4.4.4.1.5.7 Answer 31

True.

Back to Question 31 (p. 1969)

4.4.4.1.5.8 Answer 30

False. The Button and the Label are lined up horizontally with the Button on the Left and the Label on the right. The FlowLayout manager places components from left to right in the order that they are added to the container. The Button was added before the Label. See Java094.

Back to Question 30 (p. 1968)

4.4.4.1.5.9 Answer 29

True. See Java094.

Back to Question 29 (p. 1966)

4.4.4.1.5.10 Answer 28

False. The description of the mouse button is reversed. When you move your mouse pointer into the client area of the Frame without pressing a mouse button, the coordinates of the mouse pointer appear directly above the pointer. As you move the mouse pointer around in the client area, the coordinates of the pointer continue to be displayed above the pointer.

If you press one of the mouse buttons while moving the mouse in the client area, the coordinates of the point where you pressed the button appear and remain there until you release the mouse button, at which time the coordinates of the mouse pointer resume being displayed.

Clicking the X-button terminates the program and returns control to the operating system.

See Java092.

Back to Question 28 (p. 1965)

4.4.4.1.5.11 Answer 27

True. See Java092.

Back to Question 27 (p. 1965)

4.4.4.1.5.12 Answer 26

True. See Java092.

Back to Question 26 (p. 1965)

4.4.4.1.5.13 Answer 25

False. The `MouseEventListener` interface declares only the following two methods. The `mousePressed` method is declared in the `MouseListener` interface. See Java092.

- `public abstract void mouseDragged(MouseEvent e)`
- `public abstract void mouseMoved(MouseEvent e)`

Back to Question 25 (p. 1964)

4.4.4.1.5.14 Answer 24

True. See Java087.

Back to Question 24 (p. 1963)

4.4.4.1.5.15 Answer 23

False. Clicking the X-button on either Frame object causes both Frame objects to disappear, terminating the program, and returning control to the operating system. See Java082.

Back to Question 23 (p. 1961)

4.4.4.1.5.16 Answer 22

False. Multiple listener objects can be, and often are registered on a single source object. Similarly, a single listener object can be registered on multiple source objects. In many, but not all such cases, the listener object must be able to identify which source fired the event in order to take the appropriate action. However, in some situations, the appropriate action is independent of the identity of the source. See Java082.

Back to Question 22 (p. 1961)

4.4.4.1.5.17 Answer 21

False. Although new coordinates are displayed with each mouse click, the old coordinates are not erased. See Java081.

Back to Question 21 (p. 1960)

4.4.4.1.5.18 Answer 20

True. See Java 081. Note, however that the `setDefaultCloseOperation` method probably did not exist when Java081 was written. When used as shown in the code for this question, that method causes the program to terminate and return control to the operating system when the user clicks the X-button. Four different default actions can be specified for the X-button:

- `DO_NOTHING_ON_CLOSE`
- `HIDE_ON_CLOSE`
- `DISPOSE_ON_CLOSE`
- `EXIT_ON_CLOSE`

Back to Question 20 (p. 1959)

4.4.4.1.5.19 Answer 19

False. In order for this to be true, it would be necessary to override the `WindowClosing` method instead of the `WindowClosed` method. See Java080.

Back to Question 19 (p. 1958)

4.4.4.1.5.20 Answer 18

False: The default layout manager for a `Frame` object is `BorderLayout` . See Java080.

Back to Question 18 (p. 1958)

4.4.4.1.5.21 Answer 17

True. See Java080.

Back to Question 17 (p. 1957)

4.4.4.1.5.22 Answer 16

True. See Java080.

Back to Question 16 (p. 1955)

4.4.4.1.5.23 Answer 15

True. See Java080.

Back to Question 15 (p. 1955)

4.4.4.1.5.24 Answer 14

True. See Java080.

Back to Question 14 (p. 1955)

4.4.4.1.5.25 Answer 13

True. See Java080.

Back to Question 13 (p. 1955)

4.4.4.1.5.26 Answer 12

False. There is a class of mouse events that includes most of the events normally associated with mouse action and there is a matching **interface** definition that is used to define a listener class for those events. See Java080.

Back to Question 12 (p. 1954)

4.4.4.1.5.27 Answer 11

True. See Java080.

Back to Question 11 (p. 1954)

4.4.4.1.5.28 Answer 10

True. See Java080.

Back to Question 10 (p. 1954)

4.4.4.1.5.29 Answer 9

False. An event **source** is an object that has the ability to determine when an interesting event has occurred, and to notify **listener** objects of the occurrence of the event. See Java080.

Back to Question 9 (p. 1954)

4.4.4.1.5.30 Answer 8

True. See Java080.

Back to Question 8 (p. 1954)

4.4.4.1.5.31 Answer 7

True.

Back to Question 7 (p. 1954)

4.4.4.1.5.32 Answer 6

False. This is *multicasting*. The one-to-one case is often referred to as unicasting. See Java077.

Back to Question 6 (p. 1954)

4.4.4.1.5.33 Answer 5

True. See Java077.

Back to Question 5 (p. 1954)

4.4.4.1.5.34 Answer 4

False. It is very important to understand that Swing is an extension of, and not a replacement for the AWT. Therefore, as students, we cannot simply skip over an understanding of the AWT and move on to Swing. The AWT is the foundation for Swing. See Java073.

Back to Question 4 (p. 1954)

4.4.4.1.5.35 Answer 3

False. `com.sun.java.swing.*` was the package for Swing in JDK 1.1.6. However, sometime between then and the release of Java SE 7, the package containing Swing components was changed to `javax.swing.*`

Back to Question 3 (p. 1953)

4.4.4.1.5.36 Answer 2

True. See Java073.

Back to Question 2 (p. 1953)

4.4.4.1.5.37 Answer 1

True. See Java073.

Back to Question 1 (p. 1953)

4.4.4.1.6 Miscellaneous

This section contains a variety of miscellaneous information.

4.5.1.1 Table of contents

- Preface (p. 1985)
- Links to Chapters (p. 1985)
- Miscellaneous (p. 1985)

4.5.1.2 Preface

- This is the main page for links to JSP content that is part of the course named *ITSE2317 - Java Programming (Intermediate)* at Austin Community College in Austin, TX.
- The material in the chapters is sequential and is designed for progressive study. Most chapters contain material that references concepts and code covered in prior chapters.
- Assignments and the section exam are located in Blackboard.

4.5.1.3 Links to Chapters

- 01 - Getting Started with JSP ⁴⁸⁰
- 02 - Web Programming Model ⁴⁸¹
- 03 - HTML and CSS Fundamentals ⁴⁸²
- 04 - JSP Fundamentals ⁴⁸³
- 05 - Form Processing with JSP ⁴⁸⁴
- 06 - Working with Java Classes ⁴⁸⁵
- 07 - Cookies with JSP ⁴⁸⁶
- 08 - Sessions with JSP ⁴⁸⁷
- 09 - Assessment Questions ⁴⁸⁸

4.5.1.4 Miscellaneous

Due to the dynamic nature of the material, the content at the links above is periodically updated and the links themselves may change. While you are welcome to print the pages, I recommend bookmarking THIS MAIN PAGE for future reference and NOT the subordinate links. The links to the resources may change but they will always be kept up-to-date on this main page. Since the links may change, by bookmarking this main page, you will have access to the current content and working links.

I hope you enjoy the course.

Chapter 5

INEW 2338 Advanced Java (Web)

5.1 Preface

5.1.1 Java4510: Preface to INEW 2338¹

Revised: Thu Jun 02 14:40:19 CDT 2016

This page is included in the following Books:

- *INEW2338 - Advanced Java Programming* ²
- *Object-Oriented Programming (OOP) with Java* ³

5.1.1.1 Table of Contents

- Welcome (p. 1987)
- Programming Oldies but Goodies (p. 1988)
- Downloads (p. 1988)
- Miscellaneous (p. 1988)

5.1.1.2 Welcome

Welcome to the course material for **INEW2338 - Advanced Java Programming**, which I teach at Austin Community College ⁴ in Austin, TX.

Information about the course

The college website for this course is: <http://www.austincc.edu/baldwin/> ⁵

The prerequisite for the course is ITSE2317 - Java Programming (Intermediate) ⁶ or department approval.

Each semester, the course covers **three major topics** :

- Network Programming
- Search Engines OR Servlets OR JSON
- Java EE and Frameworks

¹This content is available online at <<http://cnx.org/content/m48259/1.10/>>.

²<http://cnx.org/contents/yWyT-uhM>

³http://cnx.org/contents/-2RmHFs_

⁴<http://www.austincc.edu/>

⁵<http://www.austincc.edu/baldwin/>

⁶<http://cnx.org/contents/Rl23r3Lw>

Note: Although only one of the topics *Search Engines* , *Servlets* , or *JSON* is covered in the course in any particular semester, all three are important. The course material in the Blackboard course management program will indicate which topic is covered in the current semester.

Students are encouraged to study all three topics for their own educational purposes in order to enhance their prospects of landing a job as a Java programmer.

5.1.1.3 Programming Oldies but Goodies

While much of the material required to succeed in this course is contained in the modules in this book, a large amount of relevant material is also contained in the collection titled Programming Oldies But Goodies ⁷ , which is a work in process. The material in that collection has not yet been converted to the cnxml format required by OpenStax. Instead, the material in that collection is still in its original html format.

You would do well to familiarize yourself with that material as well.

5.1.1.4 Downloads

I encourage you to take advantage of the download options that OpenStax has to offer in order to customize this material for use in your organized courses or for personal self study.

5.1.1.5 Miscellaneous

This section contains a variety of miscellaneous information.

5.2 Network Programming

5.2.1 Java4610-Preface⁸

5.2.1.1 Table of Contents

- Discussion (p. 1989)
- What's next? (p. 1989)
- Miscellaneous (p. 1989)

5.2.1.2 Discussion

This module serves as the preface to a sub-collection of modules on network programming. The modules in this sub-collection are designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX.

5.2.1.3 What's next?

The next module is titled *Java4620: General Information* .

As you might surmise from the title, it deals with such topics as communication protocols, clients, servers, IP, TCP, ports, etc.

5.2.1.4 Miscellaneous

This section contains a variety of miscellaneous information.

- What's Next? (p. 1998)
- Miscellaneous (p. 1998)

5.2.2.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX. More specifically, it is one in a sub-collection of modules designed for teaching network programming in that course. The purpose of this module is to introduce the student to various aspects of network programming that will be incorporated into future modules.

5.2.2.3 Introduction

One of the Java books on my bookshelf makes the following analogy (*or one very similar*) . Just because you may know how to speak conversational French doesn't mean that you know how to interpret an autopsy report written in French. In order to interpret the autopsy report, you must also know a good deal about the meaning of the medical terms used in such reports.

A similar situation exist for networking. It isn't very difficult to learn how to use the Java programming language to implement some network operations. However, in order to achieve depth in this area, you probably also need to know something about the many other technical aspects of networking.

This is not a new field, and many good books have been written on the technical details of networking, you are referred to one or more of those books to gain an in-depth knowledge of networking. In particular, I would refer you to Java Network Programming¹⁰ by Elliotte Rusty Harold.

⁹This content is available online at <<http://cnx.org/content/m49533/1.2/>>.

¹⁰<http://shop.oreilly.com/product/0636920028420.do>

In addition there are many other books that contain excellent sections on network programming. I would recommend that you take a look at the following:

- *Exploring Java* by Patrick Niemeyer and Joshua Peck
- *Just Java 1.1 and Beyond* by Peter van der Linden
- *Java Primer Plus* by Tyma, Torok, and Downing
- *Java How to Program* by Deitel and Deitel

These books have been around for a long time, so you should be able to find a used copy online for a reasonable price.

For the most part, this and the next few modules will be restricted to how you can use the programming capabilities of Java to write and execute network programs and won't attempt to go into overall network programming in depth. However, a minimal amount of background information will be required, so we will attempt to provide that background in this module. Subsequent modules will use this background along with the network programming capabilities of Java to write some simple, but interesting networking programs.

5.2.2.4 Background Information

For our purposes, a network is a group of computers and other devices that are connected in some fashion for the purpose of exchanging data.

Each of the devices on the network can be thought of as a *node*, and each node has a unique address. The manner in which addresses are assigned will vary from one type of network to another, but in all cases, the address of each device must be unique so as to distinguish it from the other devices.

Addresses are numeric quantities that are easy for computers to work with, but are not easy for humans to remember. Therefore, some networks also provide names that humans can more easily remember than numbers.

Modern networks transfer data using a concept known as *packet switching*. This means that the data are encapsulated into packets that are transferred from the source to the destination. It is necessary to extract the data from one or more packets at the destination and use it to reconstruct the original message.

5.2.2.4.1 Communication Protocol

In order for two or more computers connected to a network to be able to exchange data in an orderly manner, they must adhere to a mutually acceptable communication protocol. The protocol defines the rules by which they communicate.

Teaching your children to say *please* and *thank you* involves teaching them something about a protocol. If they occasionally forget to say please, however, they will probably get the cookie anyway.

If a computer protocol requires the participating computers to say please, and they forget to say please, they probably won't get the cookie.

There are many protocols available. For example, the HTTP protocol defines how web browsers and servers communicate and the SMTP protocol defines how email is transferred (*we will write programs that implement part of the HTTP protocol*).

Note here that I have been discussing application protocols that operate at the surface level. We will also be making mention of lower-level protocols that operate below the application level. Fortunately, as high-level Java programmers, we don't have to be too concerned about the lower-level protocols. We'll let the systems people worry about them.

5.2.2.4.2 Network Layers

Networks are *logically* separated into layers ranging from the *Application Layer* at the top to the *Physical Layer* at the bottom. The technical details of network layering are beyond the scope of this

module. Fortunately, you will be able to write useful network programs using Java without understanding the details of network layering.

The *Application Layer* is the layer that delivers data to the user. The layers below that are involved with getting data from the *Application Layer* at one end of the conversation to the *Application Layer* at the other end. For the most part, we will be concerned only with the *Application Layer* .

5.2.2.4.3 Clients and Servers

In these modules, we will be concerned with networked communications that involve *client* computers and a *server* computers. How do we know which is which?

For the purposes of our studies, it will be sufficient to say that the client always initiates the conversation, and the server waits and listens for a client to initiate a conversation.

5.2.2.4.4 IP, TCP, and UDP

We need to know something about the following acronyms:

- IP
- TCP
- UDP

5.2.2.4.4.1 IP

IP , which stands for *Internet Protocol* , is the protocol that will be involved below the *Application Layer* to move our data between a client and a server. Beyond knowing that it exists, we probably don't need to concern ourselves with the fact that **IP** is being used

In fact, in some situations, some other protocol could be used to move our data between a client and a server. As long as it works, we really don't care too much.

In a nutshell, **IP** is a network protocol that moves packets of data from a source to a destination. As the name implies, this is the protocol normally used on the Internet.

5.2.2.4.4.2 TCP

It is sometimes important to be able to have confidence that all packets that make up a message arrive at the destination undamaged and in proper order.

The *Transmission Control Protocol* (**TCP**) was added to **IP** to give each end of a connection the ability to acknowledge receipt of **IP** packets and to request retransmission of corrupted or lost packets. Also **TCP** makes it possible to put the packets back together at the destination in the same order that they were sent.

Therefore, you will often hear people using both acronyms in the same breath, as in **TCP/IP** . The two work together to provide a *reliable* method of encapsulating a message into data packets, sending the packets to a destination, and reconstructing the message from the packets at the destination.

5.2.2.4.4.3 UDP

Sometimes it may not be critically important that all the packets arrive at the destination or that they arrive in the proper order. Further, sometimes, you may not want to incur the time delays and overhead cost associated with those guarantees.

For example, if one computer is sending date and time information to another computer every 100 milliseconds, and the data in the packets is displayed on a digital clock as it is received, you might prefer

that each packet make the trip as quickly as possible even if that means that occasionally a packet will be lost or damaged.

The *User Datagram Protocol* (**UDP**) is available to support this type of operation. **UDP** is often referred to as an *unreliable* protocol because there is no guarantee that a series of packets will arrive in the right order, or that they will arrive at all.

As Java programmers, we have the choice of **TCP** or **UDP** , and we need to know enough about the characteristics of each to be able to make informed choices between them.

5.2.2.4.5 IP Addresses

We don't really need to know very much about **IP** to be able to use it, but we do need to know about the addressing scheme used in **IP** .

Every computer attached to an **IP** network has a unique address, typically consisting of four bytes or 32 bits (*IPv4* ¹¹) .

Thirty-two bits are sufficient to define a large number of unique addresses, but the manner in which addresses are allocated is wasteful, and many of the addresses that have been allocated are not being used.

Efforts are underway to expand the number of possible unique addresses to a much larger number. The planned number is the number of unique addresses that can be represented with a 128-bit address. The new scheme is known as *IPv6* ¹² .

For human consumption, we usually convert the value of each of the bytes to an unsigned decimal value and display them connected by periods to make them easier to remember. For example, as near as I can tell, as of this writing, the **IP** address of `www.austincc.edu` ¹³ (*the college where I teach*) is **206.77.150.222** .

5.2.2.4.6 Domain Names

What do I mean by `www.austincc.edu` ¹⁴ ?

Even though we can do some tricks to make the numeric **IP** addresses easier to remember, humans don't do a very good job of remembering long strings of numbers. Humans remember words and names better. Therefore, most **IP** addresses have a corresponding name known as a *domain name* . The domain name for the **IP** address **206.77.150.222** is `www.austincc.edu` ¹⁵ .

The *Domain Name System* (DNS) was developed to translate between **IP** addresses and domain names. Whenever you log your browser onto the internet and attempt to connect to a server using its domain name, the browser first communicates with a DNS server to learn the corresponding numeric **IP** address. The numeric **IP** address (*and not the domain name*) is encapsulated into the data packets and used by the internet protocol to route those packets from the source to the destination.

(You should also be able to enter 206.77.150.222 into the address field of your browser and access the college where I teach.)

We will learn how to use the Java **InetAddress** class to find the domain name corresponding to an **IP** address, and to find the **IP** address corresponding to a domain name.

5.2.2.4.7 What is Your IP Address?

Do you have an **IP** address and a *domain name* ?

If (*like me*) you use a commercial Internet Service Provider (ISP) for your Internet service at home, you probably don't have a fixed **IP** address or a fixed *domain name* . Rather, the ISP has a block of

¹¹<http://en.wikipedia.org/wiki/IPv6>

¹²<http://en.wikipedia.org/wiki/IPv6>

¹³<http://www.austincc.edu>

¹⁴<http://www.austincc.edu>

¹⁵<http://www.austincc.edu>

IP addresses reserved. When you subscribe to the ISP, the ISP temporarily assigns an **IP** address to you. That IP address may or may not change over time, but probably will change unless you pay the extra fee for a fixed IP address.

On the other hand, I currently pay for server space from a company in North Carolina under the domain name www.dickbaldwin.com¹⁶. My domain has an IP address of **98.129.229.162**. For as long as I continue to pay the bill, that domain name and that IP address will be assigned to me for use as my personal website.

I suppose that the company could change the IP address at some point provided that they make certain that all of the domain name servers get updated to reflect the new IP address that corresponds to the domain name.

5.2.2.4.8 Ports

Each server computer that you may connect to will be logically organized into *ports*. These are not physical ports in the sense of the VGA or HDMI port on the back of your computer. Rather, they are simply logical sub-addresses which you provide to the operating system on the server so that the operating system can cause the appropriate server software to *"answer the call."* We will write a simple server software package that will service several different ports on independent threads in a future module.

One of the Java books on my bookshelf refers to the **IP** address as being analogous to the telephone number of a company and the *port* to be analogous to the employee's telephone extension within that company. (*At least that is how telephone systems in companies were organized when I was working in industry.*)

Theoretically, there are 65,535 available ports. Port numbers between 1 and 1023 are predefined to be used for certain standard services. For example, if you want to connect with server software that communicates using the HTTP protocol, you would normally connect to port 80 on the server of interest.

Similarly, if you want to connect to a port that will tell you the time, you should connect to port 13, assuming that you can find a server somewhere that is willing to support port 13. If you want to connect to a port that will simply echo whatever you send to it (*usually for test purposes*), you should connect to port 7. We will write Java applications that connect to all of these ports.

In the interest of brevity, I am not going to provide a complete list of ports and their services. However, you should be able to find all the information you might need about port numbers and the services they support by starting your favorite search engine and searching for "well known ports"¹⁷.

5.2.2.4.9 Firewalls

You may have heard about *firewalls*. A firewall is the common name given to the equipment and associated software that is used to insulate the network inside of a company from the Internet at large outside the company. Typically, the firewall will restrict the degree to which computers inside the company can communicate with the Internet for security and other reasons.

5.2.2.4.10 Proxy Servers

You may also have heard about *proxy servers*. A proxy server acts as an interface between computers inside the company and the Internet at large.

Oftentimes the proxy server will have the ability to *cache* web pages for limited periods of time. For example, if ten people inside the company attempt to connect to the same Internet server and download the same web page within a (*hopefully*) short period of time, that page may be saved on the proxy server on the first attempt and then delivered to the next nine people without re-acquiring it from the outside web

¹⁶<http://www.dickbaldwin.com>

¹⁷http://en.wikipedia.org/wiki/List_of_TCP_and_UDP_port_numbers

server. This can significantly improve delivery time and reduce network traffic into and out of the company. It can also result in the delivery of stale pages in some cases.

5.2.2.4.11 Standards and Protocols

At some point, you may be interested in obtaining technical information about Internet standards and protocol specifications. A good place to start looking for such information is <http://www.w3.org/pub/WWW/Protocols/>¹⁸.

5.2.2.4.12 URL

URL is an acronym for **Uniform Resource Locator**. (*It is also the name of a class in Java.*) A URL is a pointer to a particular resource at a particular location on the Internet. A URL specifies the following:

- the protocol used to access the server (*such as http*)
- the name of the server
- the port on the server (*optional*)
- the path and name of a specific file on the server (*sometimes optional*)
- the anchor or reference point within the file (*optional*)

Sometimes the name of the file can be omitted, in which case an HTTP browser will usually append the file name **index.html** to the specified path and try to load that file. For example, as of this writing, you can connect to my home page on the HTTP server at Austin Community College using either of the following URLs:

- <http://www.austincc.edu/baldwin/>¹⁹
- <http://www.austincc.edu/baldwin/index.html>²⁰

In addition to specifying the name of the file of interest, it is also sometimes possible to specify an *anchor* or *reference* that has been established inside the file. The anchor is identified by the text following the # character in the URL.

For example, as of this writing, the following URL will take you to a specific location inside one of my modules on Java servlets.

<http://cnx.org/content/m48518/latest/#Images>²¹
 (*Note the **#Images** at the end of the URL. That is commonly known as the **anchor**.*)

The general syntax of a URL is as follows:

protocol://hostname[:port]/path/filename#ref

The port is optional, and is not normally required if you are accessing a server that provides the required service on a standard port. The browser (*or other software being used to connect*) should know which port supports the specified protocol and should connect to that port by default.

You could fill in the optional port number and use the following URL to access the same location in my servlets module, but that would simply require you to do some extra typing.

<http://cnx.org:80/content/m48518/latest/#Images>²²

However, if you were to change the 80 to a 25, you would not be able to connect and successfully communicate with the server because the server does not support the HTTP protocol on port 25. In fact, here is the text of the Firefox error message that resulted from me doing that:

"This address is restricted This address uses a network port which is normally used for purposes other than Web browsing. Firefox has canceled the request for your protection."

¹⁸<http://www.w3.org/pub/WWW/Protocols/>

¹⁹<http://www.austincc.edu/baldwin/>

²⁰<http://www.austincc.edu/baldwin/index.html>

²¹<http://cnx.org/content/m48518/latest/#Images>

²²<http://cnx.org:80/content/m48518/latest/#Images>

The Google Chrome browser simply provided the following error message when I attempted to do that.

"This webpage is not available."

When I clicked a "More" button on the Chrome error message, this is what I got:

"The webpage at <http://cnx.org:25/content/m48518/latest/#Images> might be temporarily down or it may have moved permanently to a new web address. Error code: ERR_UNSAFE_PORT"

Note, however, that we will be properly addressing port 8080 on a particular server in some future modules. Since 8080 is not a standard port, it will be necessary for us to enter the port number following a colon in order to access the material on the server.

5.2.2.5 Socket Classes and the URL Class

Java provides at least two different approaches for doing network programming (*and possibly more*), insofar as the web is concerned. The two approaches are associated with

- The **Socket**, **DatagramSocket**, and **ServerSocket** classes
- The **URL**, **URLEncoder**, and **URLConnection** classes.

5.2.2.5.1 Socket Programming

Socket programming primarily makes use of two socket classes named **Socket** and **DatagramSocket** along with the **ServerSocket** class. The first two socket classes represent **TCP** and **UDP** communications respectively.

Generally, the two socket classes are used to implement both *clients* and *servers*, while the **ServerSocket** class is only used to implement *servers*. We will see several examples of socket programming in this series of modules.

Socket programming provides a low-level approach by which you can connect two computers for the exchange of data. One of those is generally considered to be the *client* while the other is considered to be the *server*.

Although the distinction between client and server is becoming less clear each day, there is one fundamental distinction that is inherent in the Java programming language.

The client initiates conversations with servers, while servers block and wait for a client to initiate a conversation.

The governing application-level protocol will determine what happens after the connection is made and the conversation has begun. The fact that the two computers can connect doesn't necessarily mean that they can communicate. In order to communicate, they must implement some mutually acceptable application protocol

For example, the fact that I can dial a telephone number for a telephone located in France doesn't mean that I can communicate with the person who answers the phone. I don't know how to speak the French language. Unless the person who answers the phone speaks English, very little communication is likely to take place.

Socket programming has been around for quite a while in the Unix world. Java simply makes it easier by encapsulating much of the complexity of socket programming into classes, and allowing you to approach the task on an object-oriented basis.

On the other hand, according to some authors, some of the generality and capability that Unix socket programmers have enjoyed has been lost in the encapsulation process.

Basically, socket programming makes it possible for you to cause data to flow in a full-duplex mode between a client and a server. This data flow can be viewed in almost exactly the same way that we view data flow to and from a disk: as a stream of bytes.

As with most stream data processing, the system is responsible for moving the bytes from the source to the destination. It is the responsibility of the programmer to assign meaning to those bytes.

Assigning meaning takes on a special significance for socket programming. In particular, as mentioned above, it is the responsibility of the programmer to implement a mutually acceptable communication protocol at the application level to cause the data to flow in an orderly manner.

An application protocol is a set of rules by which the programs in the two computers can carry on a conversation and transfer data in the process. For example, we will also write a program that implements a very abbreviated form of the HTTP protocol to download web pages from a server and display them.

We will also write a program that functions as an (*abbreviated*) HTTP server to deliver web pages to a client and also supports the *echo* protocol for both TCP and UDP programming.

Each of these programs will involve adherence to a fairly simple protocol. (*At least the part that we implement will be fairly simple*) .

In addition, we will also write a program that obtains the date and time from another computer. In this case, the protocol will be about as simple as it can possibly be. The client will simply make the connection and listen for a string containing the date and time. This will be sort of like dialing the local time service, except that we won't have to listen to an advertisement before getting the time.

The bottom line is that with socket programming, it is easy to write code that will cause a stream of bytes to flow in both directions between a client and a server. This is no more difficult than causing a stream of bytes to flow in both directions between memory and a file on a disk.

However, getting the bytes to flow is the easy part. Beyond that, you must do all of the programming to implement an application protocol that is understood by both the client and the server.

5.2.2.5.2 URL Programming

URL programming occurs at a higher level than socket programming, and in theory represents a very powerful idea.

In theory, by using the **URL** class, you can open a connection to a resource on the web, specified by a **URL** object, and simply call the **getContent** method on that **URL** object. The content of the resource will then be magically downloaded and will appear as an object on the client machine, even if it requires an application protocol that didn't exist when you wrote the program, and contains content that you didn't understand when you wrote the program.

This description may be a bit of an overstatement, but it is pretty close to the claims being made. This is a powerful idea, which may or may not bear fruit in the future.

If fully implemented by browsers, the idea means that you can place new and unusual material on a web site along with special content handlers and protocol handlers. Then a cooperating browser will use those special handlers to move that material from the web site to the client and interpret its content once it gets there without a requirement to install software (*such as plug-ins*) on the client computer on a permanent basis.

Here is what Peter van der Linden has to say about this topic in his excellent book titled *Just Java 1.1 and Beyond*:

"If a browser doesn't recognize a media type, it should be able to download the code to process it from the same place it got the file. If they ever get this working, it will be ... a good thing."

Is it working, or will they ever get it working? I don't know. If it depends on cooperation among all the major players, including the major browser vendors - probably not. Therefore, I don't plan to spend much time on the topic of protocol and content handlers until I see some evidence that it is working to such an extent that it is practically useful.

That is not to say that you couldn't use the capability right now if you were developing an intranet and wanted the clients to have access to new and unusual content. It would be necessary for you to provide the appropriate protocol and content handlers, and it would probably be necessary for the clients to run Java applications written by you instead of standard browsers to access the data.

Also, the `URL` class provides an alternative way to connect one computer to another and transfer data on a stream basis, so we will see some examples of retrieving data from a server by obtaining a `URL` connection, and then opening and servicing I/O streams between the client and the server. We will see some sample programs that make use of this technique, but we will also see that it is somewhat redundant with the socket programming approach.

5.2.2.6 A local area network

This is part of a sub-collection of modules designed for teaching network programming. Therefore, you may find some of the modules more meaningful if you are able to connect two or more computers in a local area network and run the sample programs across the network.

However, it is possible to simulate a network inside a single computer. If you are unable to create an actual network, you should be able to run all of the sample programs by simulating a network in your single computer.

5.2.2.7 The operating system

While the capabilities of Java are generally independent of the operating system in use, the manner in which an individual computer must be configured for network operation is generally not independent of the operating system.

In those cases where these modules provide instructions for configuring the computer, those instructions will assume a Windows operating system. If you are using a different operating system, you will need to translate those instructions into your operating system.

5.2.2.8 What's Next?

We will learn how to use the Java `InetAddress` class to find the domain name corresponding to an IP address, and to find the IP address corresponding to a domain name in our sample program in the next module.

5.2.2.9 Miscellaneous

This section contains a variety of miscellaneous information.

5.2.3.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX.

This module contains review questions and answers keyed to the module titled Java4620: General Information ²⁴ in the Network Programming sub-collection.

Once you study that module, you should be able to answer the review questions in this module.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

5.2.3.3 Questions

5.2.3.3.1 Question 1

True or False?

A network is a group of computers and other devices that are connected in some fashion for the purpose of exchanging data.

Go to answer 1 (p. 2008)

5.2.3.3.2 Question 2

True or False?

Each of the devices on the network can be thought of as a *node* , and each node has the same address.

Go to answer 2 (p. 2008)

5.2.3.3.3 Question 3

True or False?

Modern networks transfer data using a concept known as *packet switching* .

Go to answer 3 (p. 2008)

5.2.3.3.4 Question 4

True or False?

In order for two or more computers connected to a network to be able to exchange data in an orderly manner, each computer must use a different protocol. The protocol defines the rules by which they communicate.

Go to answer 4 (p. 2008)

²³This content is available online at <<http://cnx.org/content/m49577/1.3/>>.

²⁴<http://cnx.org/content/m49533/latest/?collection=col11441/latest>

5.2.3.3.5 Question 5

True or False?

The HTTP protocol defines how web browsers and servers communicate and the SMTP protocol defines how some email is transferred

Go to answer 5 (p. 2007)

5.2.3.3.6 Question 6

True or False?

IP is an acronym that stands for *Interconnection Protocol*.

Go to answer 6 (p. 2007)

5.2.3.3.7 Question 7

True or False?

IP is a network protocol that moves packets of data from a source to a destination. As the name implies, this is the protocol normally used on the Internet.

Go to answer 7 (p. 2007)

5.2.3.3.8 Question 8

True or False?

The *Transmission Control Protocol* (**TCP**) was added to **IP** to give each end of a connection the ability to acknowledge receipt of **IP** packets and to request retransmission of corrupted or lost packets. Also **TCP** makes it possible to put the packets back together at the destination in the same order that they were sent.

Go to answer 8 (p. 2007)

5.2.3.3.9 Question 9

True or False?

TCP and **IP** work together to provide a *reliable* method of encapsulating a message into data packets, sending the packets to a destination, and reconstructing the message from the packets at the destination.

Go to answer 9 (p. 2007)

5.2.3.3.10 Question 10

True or False?

The *User Datagram Protocol* (**UDP**) is even more reliable than **TCP/IP** in guaranteeing that a series of packets will arrive in the right order. However, **UDP** involves a high level of overhead and the data transfer rate may be slow.

Go to answer 10 (p. 2007)

5.2.3.3.11 Question 11

True or False?

Every computer attached to an **IP** network has a unique address, typically consisting of four bytes or 32 bits. Efforts are underway to expand the number of possible unique addresses to a much larger number. The planned number is the number of unique addresses that can be represented with a 128-bit address.

Go to answer 11 (p. 2007)

5.2.3.3.12 Question 12

True or False?

For human consumption, we usually convert the value of each of the IP address bytes to an unsigned decimal value and display them connected by periods to make them easier to remember. For example, a typical **IP** address might be **206.77.150.222** .

Go to answer 12 (p. 2007)

5.2.3.3.13 Question 13

True or False?

Most **IP** addresses have a corresponding name known as a *domain name* .

Go to answer 13 (p. 2007)

5.2.3.3.14 Question 14

True or False?

The **Domain Name** of a destination server is encapsulated into data packets and used by the internet protocol to route those packets from the source to the destination.

Go to answer 14 (p. 2007)

5.2.3.3.15 Question 15

True or False?

The Java **InetAddress** class can often be used to find the domain name corresponding to an **IP** address, and to find the **IP** address corresponding to a domain name.

Go to answer 15 (p. 2006)

5.2.3.3.16 Question 16

True or False?

Each server computer that you may connect to will be logically organized into *ports* . Theoretically, there are a large number of available ports. A subset of those port numbers are predefined to be used for certain standard services. For example, if you want to connect with a public server that communicates using the HTTP protocol, you would normally connect to port 80 on the server of interest.

Go to answer 16 (p. 2006)

5.2.3.3.17 Question 17

True or False?

A **firewall** is the common name given to the equipment and associated software that is used to improve the communication speed of computers inside of a company with the Internet at large outside the company.

Go to answer 17 (p. 2006)

5.2.3.3.18 Question 18

True or False?

A **proxy server** is the common name given to the equipment and associated software that is used to insulate the network inside of a company from the Internet at large outside the company. Typically, the firewall will restrict the degree to which computers inside the company can communicate with the Internet for security and other reasons.

Go to answer 18 (p. 2006)

5.2.3.3.19 Question 19

True or False?

URL is an acronym for **Uniform Resource Locator** . (*It is also the name of a class in Java.*) A **URL** is a pointer to a particular resource at a particular location on the Internet.

Go to answer 19 (p. 2006)

5.2.3.3.20 Question 20

True or False?

A **URL** specifies the following:

- the protocol used to access the server (*such as http*)
- the name of the server
- the port on the server (*optional*)
- the path and name of a specific file on the server (*sometimes optional*)
- the anchor or reference point within the file (*optional*)

Go to answer 20 (p. 2006)

5.2.3.3.21 Question 21

True or False?

Java provides at least two different approaches for doing network programming (*and possibly more*) , insofar as the web is concerned. The two approaches are associated with

- The **Connector** , **DatagramConnector** , and **ServerConnector** classes
- The **URL**, **URLEncoder**, and **URLConnection** classes.

Go to answer 21 (p. 2006)

5.2.3.3.22 Question 22

True or False?

The two socket classes named **Socket** and **DatagramSocket** represent **TCP** and **UDP** communications respectively.

Go to answer 22 (p. 2005)

5.2.3.3.23 Question 23

True or False?

Generally, the **Socket** and **DatagramSocket** classes are used to implement both *clients* and *servers* , while the **ServerSocket** class is only used to implement *servers* .

Go to answer 23 (p. 2005)

5.2.3.3.24 Question 24

True or False?

Although the distinction between client and server is becoming less clear each day, there is one fundamental distinction that is inherent in the Java programming language.

The server initiates conversations with clients, while clients block and wait for a server to initiate a conversation.

Go to answer 24 (p. 2005)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.2.3.4 Answers

5.2.3.4.1 Answer 24

False.

Although the distinction between client and server is becoming less clear each day, there is one fundamental distinction that is inherent in the Java programming language.

The client initiates conversations with servers, while servers block and wait for a client to initiate a conversation.

Go back to Question 24 (p. 2003)

5.2.3.4.2 Answer 23

True.

Go back to Question 23 (p. 2003)

5.2.3.4.3 Answer 22

True.

Go back to Question 22 (p. 2003)

5.2.3.4.4 Answer 21

False.

Java provides at least two different approaches for doing network programming (*and possibly more*) , insofar as the web is concerned. The two approaches are associated with

- The **Socket** , **DatagramSocket** , and **ServerSocket** classes
- The **URL**, **URLEncoder**, and **URLConnection** classes.

5.2.3.4.5 Answer 20

True.

Go back to Question 20 (p. 2003)

5.2.3.4.6 Answer 19

True.

Go back to Question 19 (p. 2003)

5.2.3.4.7 Answer 18

False. A **proxy server** is often used to improve the communication speed of computers inside of a company with the Internet at large outside the company. For example, if ten people inside the company attempt to connect to the same Internet server and download the same web page within a (*hopefully*) short period of time, that page may be saved on the proxy server on the first attempt and then delivered to the next nine people without re-acquiring it from the outside web server. This can significantly improve delivery time and reduce network traffic into and out of the company.

Go back to Question 18 (p. 2002)

5.2.3.4.8 Answer 17

False. A firewall is the common name given to the equipment and associated software that is used to insulate the network inside of a company from the Internet at large outside the company. Typically, the firewall will restrict the degree to which computers inside the company can communicate with the Internet for security and other reasons.

Go back to Question 17 (p. 2002)

5.2.3.4.9 Answer 16

True.

Go back to Question 16 (p. 2002)

5.2.3.4.10 Answer 15

True.

Go back to Question 15 (p. 2002)

5.2.3.4.11 Answer 14

False. The *Domain Name System* (DNS) was developed to translate between **IP** addresses and domain names. Whenever you log your browser onto the internet and attempt to connect to a server using its domain name, the browser first communicates with a DNS server to learn the corresponding numeric **IP** address. The numeric **IP** address (*and not the domain name*) is encapsulated into the data packets and used by the internet protocol to route those packets from the source to the destination.

Go back to Question 14 (p. 2002)

5.2.3.4.12 Answer 13

True.

Go back to Question 13 (p. 2002)

5.2.3.4.13 Answer 12

True.

Go back to Question 12 (p. 2002)

5.2.3.4.14 Answer 11

True.

Go back to Question 11 (p. 2001)

5.2.3.4.15 Answer 10

False. The *User Datagram Protocol* (**UDP**) is often referred to as an *unreliable* protocol because there is no guarantee that a series of packets will arrive in the right order, or that they will arrive at all.

Go back to Question 10 (p. 2001)

5.2.3.4.16 Answer 9

True.

Go back to Question 9 (p. 2001)

5.2.3.4.17 Answer 8

True.

5.2.4.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX. More specifically, it is one in a sub-collection of modules designed for teaching network programming in that course. The purpose of this module is to introduce the student to the **InetAddress** class that can be used to deal with *IP addresses* and *domain names* .

5.2.4.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.2.4.2.1.1 Figures

- Figure 1 (p. 2012) . Program output.
- Figure 2 (p. 2013) . The list of Google IP addresses.
- Figure 3 (p. 2014) . The IP Address for my localhost.
- Figure 4 (p. 2015) . Name and IP address of my localhost.
- Figure 5 (p. 2016) . Canonical host name for Google.
- Figure 6 (p. 2018) . Google host name using reverse lookup.

5.2.4.2.1.2 Listings

- Listing 1 (p. 2012) . Beginning of the program.
- Listing 2 (p. 2013) . Display the Google InetAddress objects.
- Listing 3 (p. 2014) . Get InetAddress object for localhost.
- Listing 4 (p. 2015) . Extract name and IP address of my localhost.
- Listing 5 (p. 2016) . Get and display canonical host name for Google.
- Listing 6 (p. 2017) . Do a reverse lookup on Google.
- Listing 7 (p. 2018) . End of the program.
- Listing 8 (p. 2019) . Complete program listing.

²⁵This content is available online at <<http://cnx.org/content/m49534/1.5/>>.

5.2.4.3 General background information

Every computer attached to an IP network has a unique 32-bit or 128-bit IP address.

For human consumption, we usually convert each of the bytes in the IP address to an unsigned decimal value and display them connected by periods to make them easier to remember. As of this writing, the IP address of `www.austincc.edu`²⁶ (*the college where I teach*) is 206.77.150.222.

The domain name

What do we mean when we speak of `www.austincc.edu`²⁷ ?

Each IP address can have a corresponding name known as a *domain name* . The *domain name* for the IP address 206.77.150.222 is `www.austincc.edu`²⁸ .

For example, I can enter either the IP address or the domain name into the address field of my browser and use it to connect to the ACC web site.

The Domain Name System (DNS)

The *Domain Name System (DNS)* was developed to translate between IP addresses and domain names. Whenever you log your browser onto the internet and attempt to connect to a server using its *domain name* , the browser first communicates with a DNS server to learn the corresponding numeric IP address. The numeric IP address is encapsulated into the data packets and used by the internet protocol to route those packets from the source to the destination.

The InetAddress class

We will learn how to use methods of the Java `InetAddress` class to find the IP address corresponding to a *domain name* in this module.

We will learn how to find the *canonical host name* for a given domain name.

We will learn how to obtain information about the *localhost* .

We will learn how to do a reverse lookup to find the canonical host name associated with an IP address.

Methods of the InetAddress class

The `InetAddress` class provides several `static` methods that return a reference to an object of type `InetAddress` . You can use those methods to deal with and to manipulate IP addresses and domain names.

For example, the `static getByName(String host)` method returns a reference to an `InetAddress` object representing the host whose domain name is passed as a parameter to the method. The resulting object can be used to determine the IP address and the canonical host name of the host.

There is a problem with this, however. As I will explain later, many hosts have multiple IP addresses. To accommodate this, the `InetAddress` class provides a method named `getAllByName(String host)` that can be used to get an array of references to `InetAddress` objects representing IP addresses assigned to the host.

The `getLocalHost` method returns a reference to an `InetAddress` object representing the local host computer.

There are also a variety of methods that can be called on an `InetAddress` object to get information about the host that is represented by that object.

5.2.4.4 Discussion and sample code

I will present and explain a program named `Java4630a` that illustrates various aspects of the `InetAddress` class in this module.

I will explain the program in fragments. A complete listing of the program is provided in Listing 8 (p. 2019) .

The program output

The program produces the screen output shown in Figure 1 (p. 2012) when run on my computer. However, the information regarding the `LocalHost` will be different when you run this program on your computer.

²⁶<http://www.austincc.edu>

²⁷<http://www.austincc.edu>

²⁸<http://www.austincc.edu>

Figure 1 - Program output.

```

Get and display InetAddress(es) of Google URL

Display canonical host name for Google
dfw06s39-in-f17.1e100.net
Display Google name using reverse lookup.
dfw06s39-in-f17.1e100.net
dfw06s39-in-f17.1e100.net

```

Table 5.1

I will refer to this output in context as I explain the various elements of the program.

Beginning of the program

This is a very simple program consisting solely of the **main** method in a class named **Java4630a** . The program begins in Listing 1 (p. 2012) .

Listing 1 - Beginning of the program.

```

import java.net.*;

class Java4630a{
public static void main(String[] args){
try{
System.out.println(
"Get and display InetAddress(es) of Google URL");
InetAddress[] addresses =
InetAddress.getAllByName("www.google.com");

```

Table 5.2

Domain names and IP addresses

There is not necessarily a one-to-one correspondence between IP addresses and domain names. In fact there can be a many-to-one correspondence between the two.

Every computer on the Internet must have a unique IP address, but multiple computers can have (*or can respond to*) the same domain name. For example, if the domain name, `www.google.com`²⁹, were required to apply to a single computer, that computer would require an enormous amount of bandwidth and processing power to accommodate all of the search requests that are made to that domain name every second of every day.

The `getAllByName` method

The `InetAddress` class provides a static method named `getAllByName` that takes the domain name of a host as an incoming parameter and returns an array containing references to one or more objects of type `InetAddress`. Each object contains an IP address and some other information related to the domain name. The set of `InetAddress` objects in the array contain all of the IP addresses that are currently assigned to that domain name.

Get all for Google

The code in Listing 1 (p. 2012) calls the `getAllByName` method passing the domain name for Google as a parameter. It receives a reference to an array containing references to one or more `InetAddress` objects. The set of `InetAddress` objects encapsulate a list of five IP addresses that are currently assigned to Google.

Display the `InetAddress` objects

Listing 2 (p. 2013) contains a `for` loop that displays the `toString` version of the information encapsulated in each of the `InetAddress` objects.

Listing 2 - Display the Google `InetAddress` objects.

```
for(int cnt=0; cnt<addresses.length;cnt++){
    System.out.println(addresses[cnt]);
} //end for loop
```

Table 5.3

Figure 2 (p. 2013) shows the output produced by Listing 1 (p. 2012) and Listing 2 (p. 2013).

Figure 2 - The list of Google IP addresses.

```
Get and display InetAddress(es) of Google URL
www.google.com/173.194.115.83
www.google.com/173.194.115.84
www.google.com/173.194.115.80
www.google.com/173.194.115.81
www.google.com/173.194.115.82
```

Table 5.4

Everything to the left of the slash in the last five lines of Figure 2 (p. 2013) shows the domain name. Everything to the right of the slash shows the IP addresses. Note that there are duplicate domain names but there are no duplicate IP addresses.

²⁹<http://www.google.com>

Why only five IP addresses?

I was surprised that there are only five IP addresses in the list. Surely Google needs more than five front-end computers to handle the thousands of incoming requests that it receives every second of every day.

Upon further investigation I noticed that if I run the same program over and over, I am likely to get different sets of five IP addresses on different runs. This suggests that in some fashion, the `getAllByName` method limits the number of `InetAddress` objects to only five of the potentially hundreds of IP addresses that are assigned to a particular host. However, this is not mentioned in the Oracle documentation. The documentation states:

"Given the name of a host, returns an array of its IP addresses, based on the configured name service on the system."

There is clearly more going on here than I understand.

The localhost

The computer that you are using to read this module online also has an IP address and a name. The IP address, the name, and perhaps some other things as well are grouped together under something commonly referred to as **localhost**. In other words, the IP address of your localhost is the IP address of the computer that you are using to read this module.

Get InetAddress object for localhost

The code in Listing 3 (p. 2014) calls the static `getLocalHost` method of the `InetAddress` class to get a reference to an `InetAddress` object representing the computer that I was using when I wrote this module.

Then it passes that object's reference to the `println` method causing the overridden `toString` method belonging the `InetAddress` object to be executed.

Listing 3 - Get InetAddress object for localhost.

```
System.out.println();//blank line
System.out.println("Get and display current " +
                  "InetAddress of LocalHost");
InetAddress address = InetAddress.getLocalHost();
System.out.println(address);
```

Table 5.5**The screen output for localhost**

The string returned by the overridden `toString` method of the `InetAddress` object is shown by the second line in Figure 3 (p. 2014).

Figure 3 - The IP Address for my localhost.

```
Get and display current InetAddress of LocalHost
de118700/192.168.2.16
```

Table 5.6

Everything to the left of the slash is the name of the computer. Everything to the right of the slash is the IP address.

A local area network

Note that this is not the IP address by which the world sees my computer on the Internet. Instead, this is one of several computers on a local area network. This is the address that was assigned to this computer by the network router.

I can find the IP address that my cable modem presents to the world by entering the following text into the Google search box without the quotation marks: "get ip address"

As you can see, the second line in Figure 3 (p. 2014) contains both the name and the IP address separated by a slash character.

Extract name and IP address of my localhost

Assume that you have a reference to an `InetAddress` object and for some reason you need to extract the name and IP address as separate `String` objects. (*We will need to do this in a future module.*) The `InetAddress` class provides two methods that allow you to do that.

The code in Listing 4 (p. 2015) calls the `getHostName` and the `getHostAddress` methods on the reference to the `InetAddress` object and displays the strings returned by those methods.

Listing 4 - Extract name and IP address of my localhost.

```
System.out.println();//blank line
System.out.println("Extract and display current " +
                    "name of LocalHost");
System.out.println(address.getHostName());

System.out.println();//blank line
System.out.println("Extract and display current " +
                    "address of LocalHost");
System.out.println(address.getHostAddress());
```

Table 5.7

The code in Listing 4 (p. 2015) produces the output shown in Figure 4 (p. 2015) .

Figure 4 - Name and IP address of my localhost.

```
Extract and display current name of LocalHost
dell18700

Extract and display current address of LocalHost
192.168.2.16
```

Table 5.8

But, we already knew the answer

Of course, we already knew what the output would be based on the `toString` output in Figure 3 (p. 2014) . The difference is that in Figure 3 (p. 2014) , we only have that information as part of something

that is displayed on the screen. The code in Listing 4 (p. 2015) gives us that same information in the form of **String** objects that we can use for some purpose other than simply looking at the information on the screen. (See `googleAddress` in Listing 6 (p. 2017) for example.)

Canonical host name

The documentation describes the method named `getCanonicalHostName` partially as follows:

"Gets the fully qualified domain name for this IP address. Best effort method, meaning we may not be able to return the FQDN depending on the underlying system configuration."

One online description for a canonical host name reads as follows:

"A host machine on a network can be identified by several different names. However, each host must have one official hostname. All other hostnames are considered aliases of the canonical hostname"

Get and display canonical host name for Google

Returning now to Google, the code in Listing 5 (p. 2016) gets and displays the canonical hostname for Google.

Listing 5 - Get and display canonical host name for Google.

```
System.out.println(
    "Display canonical host name for Google");
//Get InetAddress containing one of Google's
// IP addresses.
address = InetAddress.getByName("www.google.com");
System.out.println(address.getCanonicalHostName());
```

Table 5.9

The code in Listing 5 (p. 2016) begins by getting a reference to one of the **InetAddress** objects that represent `www.google.com`³⁰. Then the `getCanonicalHostName` method is called on that object to get and display the canonical host name. The code in Listing 5 (p. 2016) produces the output shown in Figure 5 (p. 2016).

Figure 5 - Canonical host name for Google.

```
Display canonical host name for Google
dfw06s39-in-f17.1e100.net
```

Table 5.10

As you can see, this canonical host name wouldn't mean much to a human observer.

Other canonical host names

Here is a list of some canonical host names that can be obtained using code similar to that shown in Figure 5 (p. 2016). Try pasting them into your browser's address window and pressing the Enter key to see which ones access the sites that you expect and **which ones don't**.

³⁰<http://www.google.com>

- `www.google.com`³¹ : `dfw06s39-in-f17.1e100.net`
- `www.amazon.com`³² : (No canonical host name was returned.)
- `www.yahoo.com`³³ : `ir2.fp.vip.bf1.yahoo.com`
- `www.dickbaldwin.com`³⁴ : (No canonical host name was returned.)
- `www.whitehouse.gov`³⁵ : (No canonical host name was returned.)
- `www.healthcare.gov`³⁶ : `a23-207-26-194.deploy.static.akamaitechnologies.com`
- `www.austincc.edu`³⁷ : `m20677150222.austincc.edu`
- `www.ebay.com`³⁸ : `www.ebay.com`
- `www.facebook.com`³⁹ : `edge-star-shv-02-dfw1.facebook.com`
- `www.twitter.com`⁴⁰ : (No canonical host name was returned.)
- `www.foxnews.com`⁴¹ : `a96-17-203-72.deploy.akamaitechnologies.com`
- `www.cbsnews.com`⁴² : `a96-17-203-90.deploy.akamaitechnologies.com`

Reverse lookup

At one point in the history of Java, it was possible to call the `getByName` method passing the IP address as a string to do a reverse lookup on an IP address. The method would return the domain name to which the IP address was assigned. However, this changed around Java version 1.4 and some additional code is now required to do a reverse lookup.

Do a reverse lookup on Google

Listing 6 (p. 2017) does a reverse lookup on Google by passing one of the IP addresses to the `getByName` method and then calling the following methods on the `InetAddress` object that is returned:

- `getHostName`
- `getCanonicalHostName`

Listing 6 - Do a reverse lookup on Google.

```
System.out.println(
    "Display Google name using reverse lookup.");
String googleAddress = address.getHostAddress();
System.out.println(InetAddress.getByName(
    googleAddress).getHostName());
System.out.println(InetAddress.getByName(
    googleAddress).getCanonicalHostName());
```

Table 5.11

The code in Listing 6 (p. 2017) produces the output shown in Figure 6 (p. 2018) .

-
- ³¹`http://www.google.com`
 - ³²`http://www.amazon.com`
 - ³³`http://www.yahoo.com`
 - ³⁴`http://www.dickbaldwin.com`
 - ³⁵`http://www.whitehouse.gov`
 - ³⁶`http://www.healthcare.gov`
 - ³⁷`http://www.austincc.edu`
 - ³⁸`http://www.ebay.com`
 - ³⁹`http://www.facebook.com`
 - ⁴⁰`http://www.twitter.com`
 - ⁴¹`http://www.foxnews.com`
 - ⁴²`http://www.cbsnews.com`

Figure 6 - Google host name using reverse lookup.

```

    Display Google name using reverse lookup.
dfw06s39-in-f17.1e100.net
dfw06s39-in-f17.1e100.net

```

Table 5.12**The canonical host name**

To me, the most interesting thing in Figure 6 (p. 2018) is that both methods return the canonical host name. Neither method returns the domain name.

Although it isn't shown here, calling the `getHostName` method on one of the `InetAddress` objects contained in the `addresses` array in Listing 1 (p. 2012) returns the domain name or `www.google.com`⁴³. Calling the `getCanonicalHostName` on the same `InetAddress` object returns the canonical name shown in Figure 5 (p. 2016).

Apparently when you create an `InetAddress` object on the basis of the domain name, the object knows both the domain name and the canonical host name. However, when you create an `InetAddress` object using the IP address, the only name that it knows is the canonical host name.

The `InetAddress` class also has a method named `getByAddress` that apparently provides the same behavior when the IP address is converted to an array of bytes and passed to the method in that format. However, I haven't tested that method.

Can you access the site with the canonical host name

With respect to Google, the canonical host name, the domain name, or one of the IP addresses can be used in your browser address field to access the site.

However, for those websites in the above list (p. 2016) that have a canonical name that ends with `akamaitechnologies.com`, it appears that you cannot use either the canonical name or the IP address to access the web site. (*I will leave it as an exercise for the student to investigate this further.*)

The end of the program

The code in Listing 7 (p. 2018) takes care of the administrative details necessary to properly end the program.

Listing 7 - End of the program.

```

        }catch(UnknownHostException e){
            e.printStackTrace();
        }//end catch

    }//end main
} //end class Java4630a

```

Table 5.13

⁴³<http://www.google.com>

5.2.4.5 Run the program

I encourage you to copy the code from Listing 8 (p. 2019) . Compile the code and execute it while you are connected to the Internet. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

5.2.4.6 What's next?

The next module will deal with the `URL` class and the `URLEncoder` class.

5.2.4.7 Miscellaneous

This section contains a variety of miscellaneous information.

        "address of LocalHost");
    System.out.println(address.getHostAddress());

    System.out.println();//blank line
    System.out.println(
        "Display canonical host name for Google");
    //Get InetAddress containing one of Google's
    // IP addresses.
    address = InetAddress.getByName("www.google.com");
    System.out.println(address.getCanonicalHostName());
    System.out.println(
        "Display Google name using reverse lookup.");
    String googleAddress = address.getHostAddress();
    System.out.println(InetAddress.getByName(
        googleAddress).getHostName());
    System.out.println(InetAddress.getByName(
        googleAddress).getCanonicalHostName());
}catch(UnknownHostException e){
    e.printStackTrace();
} //end catch

} //end main
} //end class Java4630a

-end-
```

5.2.5.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX.

This module contains review questions and answers keyed to the module titled Java4630: The InetAddress Class ⁴⁵ in the Network Programming sub-collection.

Once you study that module, you should be able to answer the review questions in this module.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

5.2.5.3 Questions

5.2.5.3.1 Question 1

True or False?

The Java **InetAddress** class can be used to find the IP address corresponding to a **domain name** .
Go to answer 1 (p. 2024)

5.2.5.3.2 Question 2

True or False?

Many hosts have multiple IP addresses. To accommodate this, the **InetAddress** class provides a method named **getByName** that can be used to get an array of references to **InetAddress** objects representing IP addresses assigned to the host.

Go to answer 2 (p. 2024)

5.2.5.3.3 Question 3

True or False?

The **getByName** method of the **InetAddress** class returns a reference to an **InetAddress** object representing the host whose domain name is passed as a parameter to the method.

Go to answer 3 (p. 2024)

5.2.5.3.4 Question 4

True or False?

The **getLocalHost** method of the **InetAddress** class returns a reference to an array of **InetAddress** objects representing all of the computers on the local area network.

Go to answer 4 (p. 2023)

⁴⁴This content is available online at <<http://cnx.org/content/m49562/1.3/>>.

⁴⁵<http://cnx.org/content/m49534/latest/?collection=col11441/latest>

5.2.5.3.5 Question 5

True or False?

There is a one-to-one correspondence between IP addresses and domain names.

Go to answer 5 (p. 2023)

5.2.5.3.6 Question 6

True or False?

Every computer on the Internet must have a unique IP address, but multiple computers can have (or *can respond to*) the same domain name.

Go to answer 6 (p. 2023)

5.2.5.3.7 Question 7

True or False?

The computer that you are using to read this module online also has an IP address and a name. The IP address, the name, and perhaps some other things as well are grouped together under something commonly referred to as **localhost**. In other words, the IP address of your localhost is the IP address of the computer that you are using to read this module.

Go to answer 7 (p. 2023)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.2.5.4 Answers

5.2.5.4.1 Answer 7

True.

Go back to Question 7 (p. 2022)

5.2.5.4.2 Answer 6

True.

Go back to Question 6 (p. 2022)

5.2.5.4.3 Answer 5

False. There is not necessarily a one-to-one correspondence between IP addresses and domain names. In fact there can be a many-to-one correspondence between the two.

Go back to Question 5 (p. 2022)

5.2.5.4.4 Answer 4

False. The `getLocalHost` method of the `InetAddress` class returns a reference to an `InetAddress` object representing the local host computer.

Go back to Question 4 (p. 2021)

5.2.5.4.5 Answer 3

True.

Go back to Question 3 (p. 2021)

5.2.5.4.6 Answer 2

False. Many hosts have multiple IP addresses. To accommodate this, the `InetAddress` class provides a method named `getAllByName` that can be used to get an array of references to `InetAddress` objects representing all (or at least some) of the IP addresses assigned to the host.

Go back to Question 2 (p. 2021)

5.2.5.4.7 Answer 1

True.

Go back to Question 1 (p. 2021)

5.2.5.5 Miscellaneous

This section contains a variety of miscellaneous information.

5.2.6.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX. More specifically, it is one in a sub-collection of modules designed for teaching network programming in that course. The purpose of this module is to introduce the student to the **URL** class and the **URLEncoder** class.

5.2.6.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.2.6.2.1.1 Figures

- Figure 1 (p. 2026) . General syntax of a URL.
- Figure 2 (p. 2027) . Screen output from the program named Java4640a.
- Figure 3 (p. 2029) . Program output for string-parameter constructor.
- Figure 4 (p. 2030) . Building an absolute URL.
- Figure 5 (p. 2031) . An encoded string.
- Figure 6 (p. 2032) . Encoding rules.
- Figure 7 (p. 2033) . Program output.

5.2.6.2.1.2 Listings

- Listing 1 (p. 2028) . The method named display.
- Listing 2 (p. 2028) . Beginning of the program named Java4640a.
- Listing 3 (p. 2029) . Building an absolute URL.
- Listing 4 (p. 2031) . The URLEncoder.encode method.
- Listing 5 (p. 2033) . Beginning of the program named Java4640d.
- Listing 6 (p. 2034) . Open a connection to the URL.
- Listing 7 (p. 2034) . Read and display the data.
- Listing 8 (p. 2035) . The program named Java4640a.
- Listing 9 (p. 2038) . The program named Java4640d.

5.2.6.3 General background information

What is a URL?

URL is an acronym for *Uniform Resource Locator*. It is also the name of a class in Java, which is the primary topic for this module.

A URL is a pointer to a particular resource at a particular location on the Internet. As you learned in an earlier module, a URL **specifies the following** :

- protocol used to access the server (such as http),
- name of the server,
- port on the server (*optional*)
- path and name of a specific file on the server (*sometimes optional*)
- anchor or reference within the file (*optional*)

Sometimes the name of the file can be omitted, in which case an HTTP server may append the file name **index.html** to the specified path and try to load that file. For example, we will write a simple HTTP server in a future module that will attempt to deliver a file named **index.html** if the name of the file is omitted from the URL.

In addition to specifying the name of the file of interest, it is also sometimes possible to specify an anchor or reference that has been established inside the file. An example of how to take advantage of this capability was provided in an earlier module.

General syntax of a URL

The general syntax of a URL is shown in Figure 1 (p. 2026) .

Figure 1 - General syntax of a URL.
<code>protocol://hostname[:port]/path/filename#ref</code>

Table 5.14

The port number is optional, and is not normally required if you are accessing a server that provides the required service on a standard port.

Two ways to do network programming

Java provides at least two different ways to do network programming. The two ways are associated with socket classes and URL classes. The socket classes will be the topic of future modules. This module is concerned primarily with the URL class.

A higher level approach

URL programming occurs at a higher level than socket programming, and in theory represents some very powerful ideas. The powerful ideas represented by the advanced features of the URL class require an understanding of the development of protocol handlers and content handlers. I discussed this in some detail in an earlier module titled *Java4620: General Information* , and won't repeat that discussion here.

A mundane alternative

In addition to supporting the advanced concepts discussed in the earlier module, the URL class also provides a relatively mundane alternative way to connect one computer to another and transfer data on a stream basis. This module is primarily based on this capability.

5.2.6.4 Discussion and sample code

I will explain the programs named **Java4640a** and **Java4640d** in fragments. Complete listings of both programs are provided in Listing 8 (p. 2035) and Listing 9 (p. 2038) .

5.2.6.4.1 The program Java4640a

This program exercises four of the constructors and six of the methods of the `URL` class.

The program also illustrates the use of the `URLEncoder` class to convert a string containing spaces and other such characters into a UTF-8 encoded string format.

Screen output from the program named Java4640a

The output from the program is shown in Figure 2 (p. 2027) . I will refer to portions of this output while discussing the program.

Figure 2 - Screen output from the program named Java4640a.

```
Use simple string constructor for host URL
http www.austincc.edu -1 null
http://www.austincc.edu

Use simple string constructor for host plus file
http www.austincc.edu -1 /baldwin null
http://www.austincc.edu/baldwin

Use strings for protocol, host, and file
http www.austincc.edu -1 /baldwin null
http://www.austincc.edu/baldwin

Use strings for protocol host, and file
and int for port
http www.austincc.edu 80 /baldwin null
http://www.austincc.edu:80/baldwin

Construct absolute URL from host URL and relative URL
http www.austincc.edu -1 /baldwin/Index.html null
http://www.austincc.edu/baldwin/Index.html

Now use URLEncoder to create UTF-8 encoded String
http://space .tilde~.plus+.com
http%3A%2F%2Fspace+.tilde%7E.plus%2B.com
```

Table 5.15

The method named display

The code in Listing 1 (p. 2028) is a method named `display` that I wrote to illustrate some of the methods of the `URL` class, and also to serve the practical needs of displaying information contained in a `URL` object.

Listing 1 - The method named display.

```

    void display(URL url){//method to display parts of URL
    System.out.print(url.getProtocol() + " ");
    System.out.print(url.getHost() + " ");
    System.out.print(url.getPort() + " ");
    System.out.print(url.getFile() + " ");
    System.out.println(url.getRef());

    //Now display entire URL as a string.
    System.out.println(url.toString());
    System.out.println();
} //end display

```

Table 5.16

This method receives a reference to a URL object as a parameter and displays its component parts separated by space characters. Then it uses the overridden **toString** method of the URL class to display the contents of the URL object as a single **String** object.

The parts of the URL

As you can see from Listing 1 (p. 2028) , there is a method available for extracting each of the parts of a URL that were identified in the above list (p. 2026) .

Beginning of the program named Java4640a

Now that we know what the **display** method does, we can examine the code in the **main** method of the class.

Listing 2 (p. 2028) shows the beginning of the program named **Java4640a** and the beginning of the **main** method.

Listing 2 - Beginning of the program named Java4640a.

```

import java.net.*;
import java.io.*;

class Java4640a{
    public static void main(String[] args){
        Java4640a obj = new Java4640a();
        try{
            System.out.println(
                "Use simple string constructor for host URL");
            obj.display(new URL("http://www.austincc.edu"));
        }
    }
}

```

Table 5.17

Listing 2 (p. 2028) illustrates the instantiation of a URL object using the version of the constructor that expects to receive the URL in string format. *(I will ignore the exception handling code from these discussions for brevity.)*

Listing 2 (p. 2028) begins by instantiating an object of the controlling class that can be used to access the **display** method. Then it instantiates a new URL object using the string-parameter version of the constructor and passes that object to the **display** method.

As described above, the **display** method accesses each component part of the URL object and displays them separated by spaces. Then it displays the URL object using the overridden **toString** method.

Program output for string-parameter constructor

The code in Listing 2 (p. 2028) produced the output shown in Figure 3 (p. 2029) .

Figure 3 - Program output for string-parameter constructor.
<pre> Use simple string constructor for host URL http www.austincc.edu -1 null http://www.austincc.edu </pre>

Table 5.18

The -1 in Figure 3 (p. 2029) indicates that there was no port specification, and the null indicates that there was no file name specification in the *URL* passed to the constructor for the URL object.

The code fragment in Listing 2 (p. 2028) is followed by code that constructs the URL object using other overloaded versions of the constructor. Each overloaded version requires the URL information in different formats. You can view that code in Listing 8 (p. 2035) .

Building an absolute URL

I will to skip that code and move down to a more interesting case as shown by the fragment in Listing 3 (p. 2029) .

Listing 3 - Building an absolute URL.
<pre> System.out.println("Construct absolute URL from " + "host URL and relative URL"); URL baseURL = new URL("http://www.austincc.edu/baldwin/hello.html"); obj.display(new URL(baseURL, "/baldwin/Index.html")); </pre>

Table 5.19

Listing 3 (p. 2029) uses a URL constructor that requires two parameters: a URL object and a **String** object. Here is part of the somewhat cryptic description of this constructor from the Oracle documentation.

*"Creates a URL by parsing the given spec within a specified context. The new URL is created from the given context URL and the spec argument as described in RFC2396 "Uniform Resource Identifiers : Generic * Syntax" :*

What does this mean?

Let me try to explain this constructor in my own words (*with some help from Elliotte Rusty Harold*) . You can use this constructor to build an *absolute URL* from a *relative URL* .

Assume, for example, that you have written your own method to display HTML files the way that they are displayed by a browser rather than simply as a text file. Such files often contain links to relative *URL*'s

. In such a case, the link would be provided simply as a path and file name under the assumption that the path and file name can be found relative to the *base URL* containing the HTML file.

According to *Java Network Programming* by Elliotte Rusty Harold,

"In this case, you use the URL to the document that contains the link to provide the missing information."

The construction process

The code in Listing 3 (p. 2029) constructs a base URL object pointing to

```
"http://www.austincc.edu/baldwin/hello.html"
```

Then it uses the version of the constructor currently under discussion to combine that base URL object with a relative URL given by

```
"/baldwin/Index.html"
```

This produces the URL object displayed in Figure 4 (p. 2030) .

Figure 4 - Building an absolute URL.

<pre>Construct absolute URL from host URL and relative URL http www.austincc.edu -1 /baldwin/Index.html null http://www.austincc.edu/baldwin/Index.html</pre>

Table 5.20

Hopefully this example illustrates how the constructor can combine a base URL object with a relative URL to produce a new URL object that is an absolute pointer to the relative URL.

The URLEncoder class

There is one more issue that we need to examine before leaving this program: the **URLEncoder** class. This class is provided to help deal with problems arising from *spaces, special characters, non-alphanumeric characters, etc.* , that some operating systems may allow in file names but which may not be allowed in a URL.

If you need to create a URL object using a URL string that has these problems, you should first use the **encode** method of the **URLEncoder** class to convert it into an acceptable URL string.

The URLEncoder.encode method

This class provides a static method named **encode** that encodes a string representation of a URL into an acceptable format.

(Technically I believe it is correct to say that the format produced in Listing 4 is "application/x-www-form-urlencoded" and the binary encoding is UTF-8.)

The **encode** method returns a **String** object that is a cleaned-up version of the original string.

Listing 4 (p. 2031) calls the **encode** method to encode a string that was purposely constructed to contain several unsafe characters. It displays both the raw string and the encoded string for comparison.

Listing 4 - The URLEncoder.encode method.

continued on next page

```

System.out.println("Now use URLEncoder to create " +
    "UTF-8 encoded String");
System.out.println("http://space .tilde~.plus+.com");
System.out.println(URLEncoder.encode(
    "http://space .tilde~.plus+.com","UTF-8"));

```

Table 5.21**The encoded output**

The output from the code in Listing 4 (p. 2031) is shown in Figure 5 (p. 2031) .

Figure 5 - An encoded string.

```

Now use URLEncoder to create UTF-8 encoded String
http://space .tilde~.plus+.com
http%3A%2F%2Fspace+.tilde%7E.plus%2B.com

```

Table 5.22

The encoded version doesn't mean a lot to a human, but it is a format that is acceptable across a wide variety of computers. In case you are interested, the encoding rules are shown in Figure 6 (p. 2032) .

The ASCII characters 'a' through 'z', 'A' through 'Z', and '0' through '9' remain the same.

The space character ' ' is converted into a plus sign '+'.
 All other characters are converted into the 3-character string "%xy", where xy is the two-digit hexadecimal representation of the lower 8-bits of the character.

The ASCII characters 'a' through 'z', 'A' through 'Z', and '0' through '9' remain the same.
 The space character ' ' is converted into a plus sign '+'.
 All other characters are converted into the 3-character string "%xy", where xy is the two-digit hexadecimal representation of the lower 8-bits of the character.

The ASCII characters 'a' through 'z', 'A' through 'Z', and '0' through '9' remain the same.

The space character ' ' is converted into a plus sign '+'.
 All other characters are converted into the 3-character string "%xy", where xy is the two-digit hexadecimal representation of the lower 8-bits of the character.

The ASCII characters 'a' through 'z', 'A' through 'Z', and '0' through '9' remain the same.
 The space character ' ' is converted into a plus sign '+'.
 All other characters are converted into the 3-character string "%xy", where xy is the two-digit hexadecimal representation of the lower 8-bits of the character.

The ASCII characters 'a' through 'z', 'A' through 'Z', and '0' through '9' remain the same.

The space character ' ' is converted into a plus sign '+'.
 All other characters are converted into the 3-character string "%xy", where xy is the two-digit hexadecimal representation of the lower 8-bits of the character.

The ASCII characters 'a' through 'z', 'A' through 'Z', and '0' through '9' remain the same.
 The space character ' ' is converted into a plus sign '+'.
 All other characters are converted into the 3-character string "%xy", where xy is the two-digit hexadecimal representation of the lower 8-bits of the character.

The ASCII characters 'a' through 'z', 'A' through 'Z', and '0' through '9' remain the same.

The space character ' ' is converted into a plus sign '+'.
 All other characters are converted into the 3-character string "%xy", where xy is the two-digit hexadecimal representation of the lower 8-bits of the character.

The ASCII characters 'a' through 'z', 'A' through 'Z', and '0' through '9' remain the same.
 The space character ' ' is converted into a plus sign '+'.
 All other characters are converted into the 3-character string "%xy", where xy is the two-digit hexadecimal representation of the lower 8-bits of the character.

The ASCII characters 'a' through 'z', 'A' through 'Z', and '0' through '9' remain the same.

The space character ' ' is converted into a plus sign '+'.
 All other characters are converted into the 3-character string "%xy", where xy is the two-digit hexadecimal representation of the lower 8-bits of the character.

All other characters are converted into the 3-character string "%xy", where xy is the two-digit hexadecimal representation of the lower 8-bits of the character.

Figure 6 - Encoding rules.

To convert a String, each character is examined in turn:
 The ASCII characters 'a' through 'z', 'A' through 'Z', and '0' through '9' remain the same.
 The space character ' ' is converted into a plus sign '+'.
 All other characters are converted into the 3-character string "%xy", where xy is the two-digit hexadecimal representation of the lower 8-bits of the character.

Table 5.23

Elliott Rusty Harold provides a **URLDecoder** class in his *Java Network Programming* book that takes a URL string in the format shown above and converts it back to its **String** representation.

5.2.6.4.2 The program Java4640d

Now it is time to put some of what you have learned to work with a program named **Java4640d** . Once again, I will explain this program in fragments. A complete listing is provided in Listing 9 (p. 2038) .

This program illustrates using a URL object to connect to a URL and to read a file from that URL as an input stream. As we will see later, we can and will do the same thing using sockets in future modules.

Your computer must be online for this program to run properly. Otherwise, it will throw an exception of type **UnknownHostException** .

Program output

The output from the program is a display of the contents of the file named **page1.html** in a raw text format. Thus, all of the HTML tags are visible.

(Of course, you can modify the program to download and display a different file on the same or a different website.)

As of January 2014, the output for the beginning of the file was as shown in Figure 7 (p. 2033) . *(The file is much longer than that shown.)*

(I may modify the contents of this file from time to time, so if you compile and run this program later, you may get different results.)

Figure 7 - Program output.

```

<!doctype html public "-//w3c//dtd html 4.0 transitional//en">
<html>

<h2>
The following is a centered two-column table</h2></center>

```

Table 5.24**The beginning of the program**

The program begins in Listing 5 (p. 2033) .

Listing 5 - Beginning of the program named Java4640d.

```

import java.net.*;
import java.io.*;

class Java4640d{
public static void main(String[] args){
String dataLine;
try{
//Get a URL object
URL url = new URL(
"http://www.austincc.edu/baldwin/page1.html");

```

Table 5.25

As before, I will ignore the exception-handling code while discussing this program.

Create a URL object

As you saw in the previous program, the URL class has several different constructors, each of which can create a new URL object on the basis of URL information provided as parameters to the constructor. The constructors differ in terms of how the URL information is provided.

Listing 5 (p. 2033) creates a URL object that points to the file named `page1.html` in the directory named `baldwin` on the server at Austin Community College where I teach.

No port was specified

The URL object will not contain a port specification because I didn't provide a port number. Later when we use one of the methods of the URL class along with this URL object to make a connection to the server, the connection will, by default, be made to port 80 which is the standard port for servers that support the HTTP protocol.

In other words, when the port is not provided (*the URL object contains a port number of -1*), the connection method of the URL class will use the protocol portion of the URL to decide which port to connect to.

Open a connection to the URL

Once you have a URL object, there are a number of things that you can do with it. One of the things you can do with it is to open *input* and *output* streams that will be connected to the server software that is monitoring the port of interest.

The code in Listing 6 (p. 2034) opens a connection to the URL described by this URL object and returns an input stream object for reading data from the connection. This is the point where the port number defaults on the basis of the protocol specification in the URL object.

Listing 6 - Open a connection to the URL.

```
BufferedReader htmlPage =
    new BufferedReader(new InputStreamReader(
        url.openStream()));
```

Table 5.26

Be aware that only a small portion of the statement in Listing 6 (p. 2034) has to do with URL processing. The remainder of the statement has to do with the more complex topic of I/O stream processing.

Read and display the data

The remaining code in this program, as shown in Listing 7 (p. 2034), is completely straightforward. Data is read from the stream one line at a time and displayed as it is read. The `readLine` method returns `null` when there is no more data to be read from the stream and the program terminates.

Listing 7 - Read and display the data.

```
while((dataLine = htmlPage.readLine()) != null){
    System.out.println(dataLine);
} //end while loop
```

Table 5.27

Not complicated at all

As you can see, it is very easy to write a program that will connect to an HTTP server and download the contents of a specified file. There are lots of things that you do by using this as a starting point. A common assignment given to students is to add a little more knowledge and code to this and to write a crawler that will crawl the web searching for some specified file contents.

5.2.6.5 Run the programs

I encourage you to copy the code from Listing 8 (p. 2035) and Listing 9 (p. 2038). Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

5.2.6.6 What's next?

The next module in the series will deal with the `URLConnection` class.

5.2.6.7 Miscellaneous

This section contains a variety of miscellaneous information.

5.2.6.8 Complete program listings

Listing 8 - The program named Java4640a.

```
/*File Java4640a.java Copyright 1998, R.G.Baldwin Revised 01/05/14
```

```
This program exercises four of the constructors and
six of the methods of the URL class.
```

The program also illustrates the use of the `URLEncoder` class to convert a string containing spaces and other such characters into UTF-8 format.

```

*****/

import java.net.*;
import java.io.*;

class Java4640a{
    public static void main(String[] args){
        Java4640a obj = new Java4640a();
        try{
            System.out.println(
                "Use simple string constructor for host URL");
            obj.display(new URL("http://www.austincc.edu"));

            System.out.println("Use simple string constructor " +
                "for host plus file");
            obj.display(new URL(
                "http://www.austincc.edu/baldwin"));

            System.out.println(
                "Use strings for protocol, host, and file");
            obj.display(new URL(
                "http","www.austincc.edu","/baldwin"));

            System.out.println("Use strings for protocol " +
                "host, and file\n and int for port");
            obj.display(new URL(
                "http","www.austincc.edu",80,"/baldwin"));

            System.out.println("Construct absolute URL from " +
                "host URL and relative URL");
            URL baseURL = new URL(
                "http://www.austincc.edu/baldwin/hello.html");
            obj.display(new URL(baseURL,"/baldwin/Index.html"));

            System.out.println("Now use URLEncoder to create " +
                "UTF-8 encoded String");
            System.out.println("http://space .tilde~.plus+.com");
            System.out.println(URLEncoder.encode(
                "http://space .tilde~.plus+.com","UTF-8"));
        }catch(MalformedURLException |

5.2.7 Java4640r-Review⁴⁷

5.2.7.1 Table of Contents

- Preface (p. 2039)
- Questions (p. 2039)
 - 1 (p. 2039) , 2 (p. 2039) , 3 (p. 2039) , 4 (p. 2040) , 5 (p. 2040)
- Answers (p. 2041)
- Miscellaneous (p. 2042)

5.2.7.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX.

This module contains review questions and answers keyed to the module titled Java4640: The URL Class and the URLEncoder Class ⁴⁸ in the Network Programming sub-collection.

Once you study that module, you should be able to answer the review questions in this module.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

5.2.7.3 Questions

5.2.7.3.1 Question 1

True or False?

Java provides at least two different ways to do network programming. The two ways are associated with socket classes and URL classes.

Go to answer 1 (p. 2041)

5.2.7.3.2 Question 2

True or False?

Socket programming occurs at a higher level than URL programming

Go to answer 2 (p. 2041)

5.2.7.3.3 Question 3

True or False?

An object of the URL class provides a method for extracting each of the following parts of a URL:

- protocol used to access the server (such as http),
- name of the server,
- port on the server (*optional*)
- path and name of a specific file on the server (*sometimes optional*)
- anchor or reference within the file (*optional*)

Go to answer 3 (p. 2041)

⁴⁷This content is available online at <<http://cnx.org/content/m49558/1.3/>>.

⁴⁸<http://cnx.org/content/m49535/latest/?collection=col11441/latest>

5.2.7.3.4 Question 4

True or False?

The **URLEncoder** class is provided to help deal with problems arising from *spaces, special characters, non-alphanumeric characters, etc.* , that some operating systems may allow in file names but which may not be allowed in a URL.

Go to answer 4 (p. 2041)

5.2.7.3.5 Question 5

True or False?

Once you have a URL object connected to a server, you can open *input* and *output* streams that will be connected to the server software that is monitoring the port of interest.

Go to answer 5 (p. 2041)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.2.7.4 Answers

5.2.7.4.1 Answer 5

True.

Go back to Question 5 (p. 2040)

5.2.7.4.2 Answer 4

True.

Go back to Question 4 (p. 2040)

5.2.7.4.3 Answer 3

True.

Go back to Question 3 (p. 2039)

5.2.7.4.4 Answer 2

False. URL programming occurs at a higher level than socket programming.

Go back to Question 2 (p. 2039)

5.2.7.4.5 Answer 1

True.

Go back to Question 1 (p. 2039)

5.2.7.5 Miscellaneous

This section contains a variety of miscellaneous information.

5.2.8 Java4650: The URLConnection Class⁴⁹

5.2.8.1 Table of Contents

- Preface (p. 2042)
 - Viewing tip (p. 2043)
 - * Figures (p. 2043)
 - * Listings (p. 2043)
- General background information (p. 2043)
- Discussion and sample code (p. 2043)
- Run the program (p. 2046)
- What's next? (p. 2046)
- Miscellaneous (p. 2046)
- Complete program listing (p. 2046)

5.2.8.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX. More specifically, it is one in a sub-collection of modules designed for teaching network programming in that course. The purpose of this module is to introduce the student to the **URLConnection** class.

⁴⁹This content is available online at <<http://cnx.org/content/m49537/1.4/>>.

5.2.8.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.2.8.2.1.1 Figures

- Figure 1 (p. 2044) . Partial program output.

5.2.8.2.1.2 Listings

- Listing 1 (p. 2045) . Beginning of the program.
- Listing 2 (p. 2045) . Get a `URLConnection` object.
- Listing 3 (p. 2045) . Get information about the URL.
- Listing 4 (p. 2046) . The program named Java4650a.

5.2.8.3 General background information

I don't plan to say very much about the `URLConnection` class. It is an **abstract** class that can be *extended* , and it has a protected constructor that takes a `URL` object as a parameter.

It has variables or fields that contain useful information about a connection.

It has many methods that can be used to examine and manipulate an object of the class in a variety of different ways.

If you plan to use the `URL` class for the higher-lever capabilities that it offers, and you plan to write *content handlers* and *protocol handlers* , you will probably need to become very familiar with this class. In that case, you will probably want to get a copy of a good Java networking book, such as *Java Network Programming* , by Elliotte Rusty Howard, and study the use of this class in depth.

My objective here is simply to make you aware of the existence of the class and its many methods, and to provide some examples of how you can get and use an object of the class to obtain higher-level information about a connection.

5.2.8.4 Discussion and sample code

This program illustrates connecting to a `URL` and creating a `URLConnection` object.

The program uses the `URLConnection` object to obtain and display some of the "higher level" **information about the URL** :

- the `URL`
- the date last modified
- the content type

The computer must be online for this program to run properly. Otherwise, it will throw an exception of type `UnknownHostException` .

Partial program output

Figure 1 (p. 2044) shows part of the output from the program. The first three lines of output correspond to the items in the above list (p. 2043) , and are the items that we will be primarily interested in for this module.

Figure 1 - Partial program output.

```

Table 5.29**The program named Java4650a**

I will explain this program in fragments. A complete listing of the program is provided in Listing 4 (p. 2046) .

The **URLConnection** class is **abstract** , and therefore cannot be instantiated directly. However, it can be *extended* , and it has a protected constructor that requires a URL object as a parameter.

A common way to get a **URLConnection** object is to call a method on a URL object that returns an object of a subclass of the **URLConnection** class. That is the case in the sample program for this module.

I will ignore the exception handling code in the discussion of this program.

All of the code in the sample program is contained in the **main** method of the controlling class.

Beginning of the program

The beginning of the program and the beginning of the **main** method is shown in Listing 1 (p. 2045) .

Listing 1 - Beginning of the program.*continued on next page*

```

import java.net.*;
import java.io.*;
import java.util.*;

class Java4650a{
    public static void main(String[] args){
        String dataLine;
        try{
            //Get a URL object
            URL url = new URL(
                "http://www.austincc.edu/baldwin/page1.html");

```

Table 5.30

Get a URL object

The code at the bottom of Listing 1 (p. 2045) instantiates a URL object. This is essentially the same code that you saw in an earlier module, but you need to see it again here in order to understand the code that follows it.

URLConnection object

The code in Listing 2 (p. 2045) gets a **URLConnection** object by calling the **openConnection** method on the URL object instantiated earlier.

Listing 2 - Get a URLConnection object.

```
URLConnection urlConnection = url.openConnection();
```

Table 5.31

Get information about the URL

The code in Listing 3 (p. 2045) calls three methods on the **URLConnection** object to obtain three of the higher-level informational aspects of the URL:

- the URL
- the date that the file was last modified
- the content type of the file

Listing 3 - Get information about the URL.

```

System.out.println(urlConnection.getURL());
Date lastModified = new Date(
    urlConnection.getLastModified());
System.out.println(lastModified);
System.out.println(urlConnection.getContentType());

```

Table 5.32

The result of these three inquiries is shown as the first three lines of text in Figure 1 (p. 2044) .

The remaining code

Following this, the program uses the URL object to get an input stream and to display the contents of the file. However, this essentially duplicates a portion of the program in an earlier module, so I won't discuss it further here.

5.2.8.5 Run the program

I encourage you to copy the code from Listing 4 (p. 2046) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

5.2.8.6 What's next?

In the next module, I will show you how to download a simple HTML file and to render it in a way that is similar to how it would be rendered in a browser.

5.2.8.7 Miscellaneous

This section contains a variety of miscellaneous information.

5.2.8.8 Complete program listing

Listing 4 - The program named Java4650a.

```

/*File Java4650a.java Copyright 1998, R.G.Baldwin
Revised 01/05/14

```

Illustrates connecting to a URL and creating a
URLConnection object.

Uses the URL object to obtain and display
the URL, the date last modified, and the content type.

Also uses the URLConnection object to obtain an
input stream object. Then uses this object to read and
display the file.

```

*****/

```

```

import java.net.*;
import java.io.*;
import java.util.*;

```

```

class Java4650a{
    public static void main(String[] args){
        String dataLine;
        try{
            //Get a URL object
            URL url = new URL(
                "http://www.austincc.edu/baldwin/page1.html");

            //Open a connection to the URL and get a
            // URLConnection object.
            URLConnection urlConnection = url.openConnection();

            //Use the connection to get and display the URL
            System.out.println(urlConnection.getURL());

            //Use the connection to get and display the date last
            // modified.
            Date lastModified = new Date(
                urlConnection.getLastModified());
            System.out.println(lastModified);

            //Use the connection to get and display the content
            // type.
            System.out.println(urlConnection.getContentType());

            //Use the connection to get an InputStream object.
            // Use the InputStream object to instantiate a
            // DataInputStream object.
            BufferedReader htmlPage =
                new BufferedReader(new InputStreamReader(
                    url.openStream()));

```

```
//Use the DataInputStream object to read and display
// the file one line at a time.
while((dataLine = htmlPage.readLine()) != null){
    System.out.println(dataLine);
} //end while loop
} //end try
catch(Exception e){
    e.printStackTrace();
} //end catch

} //end main
} //end class Java4650a

-end-
```

5.2.9 Java4650r-Review⁵⁰

5.2.9.1 Table of Contents

- Preface (p. 2049)
- Questions (p. 2049)
 - 1 (p. 2049) , 2 (p. 2049) , 3 (p. 2049) , 4 (p. 2049) , 5 (p. 2050)
- Answers (p. 2051)
- Miscellaneous (p. 2052)

5.2.9.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX.

This module contains review questions and answers keyed to the module titled Java4650: The `URLConnection` Class⁵¹ in the Network Programming sub-collection.

Once you study that module, you should be able to answer the review questions in this module.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

5.2.9.3 Questions

5.2.9.3.1 Question 1

True or False?

The `URLConnection` class is an **abstract** class that can be *extended* . It has a protected constructor that takes a `URL` object as a parameter.

Go to answer 1 (p. 2052)

5.2.9.3.2 Question 2

True or False?

The `URLConnection` class can be instantiated directly.

Go to answer 2 (p. 2051)

5.2.9.3.3 Question 3

True or False?

A common way to get a `URLConnection` object is to call a method on a `URL` object that returns an object of a subclass of the `URLConnection` class.

Go to answer 3 (p. 2051)

5.2.9.3.4 Question 4

True or False?

The method named `openConnection` can be called on a `URL` object to get a reference to an object of a class that is a subclass of the `URLConnection` class.

Go to answer 4 (p. 2051)

⁵⁰This content is available online at <<http://cnx.org/content/m49573/1.3/>>.

⁵¹<http://cnx.org/content/m49537/latest/?collection=col11441/latest>

5.2.9.3.5 Question 5

True or False?

Three methods can be called on a **URLConnection** object to obtain the following three informational aspects of the URL:

- the URL
- the date that the file was last modified
- the content type of the file

Go to answer 5 (p. 2051)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.2.9.4 Answers

5.2.9.4.1 Answer 5

True.

Go back to Question 5 (p. 2050)

5.2.9.4.2 Answer 4

True.

Go back to Question 4 (p. 2049)

5.2.9.4.3 Answer 3

True.

Go back to Question 3 (p. 2049)

5.2.9.4.4 Answer 2

False. The **URLConnection** class is **abstract**, and therefore cannot be instantiated directly. However, it can be *extended*, and it has a protected constructor that requires a URL object as a parameter.

Go back to Question 2 (p. 2049)

5.2.9.4.5 Answer 1

True.

Go back to Question 1 (p. 2049)

5.2.9.5 Miscellaneous

This section contains a variety of miscellaneous information.

5.2.10.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX. More specifically, it is one in a sub-collection of modules designed for teaching network programming in that course. The purpose of this module is to show students how to use Java Swing to render a web page in a **JFrame** object.

5.2.10.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.2.10.2.1.1 Figures

- Figure 1 (p. 2058) . JFrame output from the program named Java4655c.
- Figure 2 (p. 2059) . Command line output from the program named Java4655c.
- Figure 3 (p. 2061) . JFrame output from the program named Java4655b.
- Figure 4 (p. 2063) . JFrame output from the program named Java4655a.

5.2.10.2.1.2 Listings

- Listing 1 (p. 2054) . Beginning of the program named Java4655c.
- Listing 2 (p. 2054) . The method named runner.
- Listing 3 (p. 2055) . Beginning of the class named Java4655cHtmlHandler.
- Listing 4 (p. 2056) . Open the URL object in a JEditorPane object.
- Listing 5 (p. 2056) . Register a hyperlink listener.
- Listing 6 (p. 2057) . Display the JEditorPane.
- Listing 7 (p. 2057) . The hyperlinkUpdate method.
- Listing 8 (p. 2060) . The constructor for the Java4655bHtmlHandler class.
- Listing 9 (p. 2061) . The HyperlinkEvent handler for Java4655b.
- Listing 10 (p. 2063) . Scrolling code in Java4655a.
- Listing 11 (p. 2065) . The program named Java4655c.
- Listing 12 (p. 2067) . The program named Java4655b.
- Listing 13 (p. 2069) . The program named Java4655a.

5.2.10.3 Discussion and sample code

In an earlier module, you learned how to connect to a website and cause a raw text version of a file to be downloaded and displayed. However, the display of raw HTML text isn't very useful, which is why rendering web browsers were invented.

In this module, you will learn how to connect to a website and cause an HTML file to be downloaded and rendered in a **JFrame** object. We will develop a program that makes it possible to follow hyperlinks much as you would expect with a commercial web browser.

5.2.10.3.1 A skeleton program - Java4655c

I will begin this explanation with a skeleton program that illustrates four important aspects of rendering a webpage in a **Swing JFrame object** :

- Getting a URL object that is connected to a webpage.
- Opening the URL object in a **JEditorPane** object.
- Displaying the **JEditorPane** in a rendered format.

- Handling hyperlink events on the **JEditorPane** .

(Note that there are alternatives to the first two items in the above list, which we will see later.)

To keep the code simple, two important aspects of webpage rendering will be omitted from this program:

- Scrolling large web pages.
- Following hyperlinks.

These capabilities will be added to other programs later in this module.

Beginning of the program named Java4655c

I will explain this program in fragments. A complete listing of the program is provided in Listing 11 (p. 2065) .

Listing 1 (p. 2054) shows the beginning of the program.

Listing 1 - Beginning of the program named Java4655c.

```
import javax.swing.*;
import javax.swing.event.*;
import javax.swing.text.html.*;
import java.net.*;
import java.awt.*;

class Java4655c{

    public static void main(String[] args){
        new Java4655c().runner(
            "http://www.austincc.edu/baldwin");
    } //end main
}
```

Table 5.33

There is nothing new in Listing 1 (p. 2054) . This code simply calls a method named runner passing a string description of a URL as a parameter.

The method named runner

The method named **runner** is shown in Listing 2 (p. 2054) .

Listing 2 - The method named runner.

```
void runner(String webSiteLink){
try{
    //Create a new URL object from the website string
    URL website = new URL(webSiteLink);
    //Instantiate an overall web page handler
    new Java4655cHtmlHandler(website);
} catch (Exception e){
    e.printStackTrace();
} //end catch
} //end runner
} //end class Java4655c
```

Table 5.34

Listing 2 (p. 2054) begins by getting a URL object that is connected to the specified webpage to satisfy the first item in the above list (p. 2053) .

Then Listing 2 (p. 2054) instantiates a new object of the class named **Java4655cHtmlHandler** passing the URL object's reference as a parameter to the constructor. From this point forward, the behavior of the program will be controlled by the object of the **Java4655cHtmlHandler** class.

Listing 2 (p. 2054) also signals the end of the class named **Java4655c** .

Beginning of the class named Java4655cHtmlHandler

The beginning of the class named **Java4655cHtmlHandler** and the beginning of the constructor for that class is shown in Listing 3 (p. 2055)

Listing 3 - Beginning of the class named Java4655cHtmlHandler.

```
class Java4655cHtmlHandler extends JFrame
                               implements HyperlinkListener{
//Constructor
public Java4655cHtmlHandler(URL website) {
    setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
    setTitle("Copyright 2014, R.G.Baldwin");
}
```

Table 5.35

There is nothing new or unusual in Listing 3 (p. 2055) with the possible exception of the fact that the class implements the interface named **HyperlinkListener** . This has two important ramifications:

- The class must provide concrete implementations of all the methods declared in the interface.
- An object of the class can serve as a listener for events of type **HyperlinkEvent** .

As you will see later, the **HyperlinkListener** interface declares only one method and it is named **hyperlinkUpdate** . The method receives one incoming parameter of type **HyperlinkEvent** .

The hyperlinkUpdate method

The documentation for the **hyperlinkUpdate** method is rather sparse, stating only that the method is *"Called when a hypertext link is updated"* and that the incoming parameter represents *"the event responsible for the update."*

As you will see later, an event occurs whenever the user touches a hyperlink in the webpage with the mouse. The **HyperlinkEvent** object encapsulates information identifying the event as being one of the following types:

- ENTERED
- EXITED
- ACTIVATED

I will pursue the three types of hyperlink events in more detail later.

Open the URL object in a JEditorPane object

Listing 4 (p. 2056) opens the URL object in a **JEditorPane** object to satisfy the second item in the above list (p. 2053) .

(I will ignore the exception handling code while explaining this program.)

Listing 4 - Open the URL object in a JEditorPane object.

```

    try{
    if(website != null) {
        //Create a JEditorPane containing the web page.
        JEditorPane html = new JEditorPane(website);
        html.setEditable(false);
    }
}

```

Table 5.36

Fortunately, the online documentation ⁵³ for the **JEditorPane** is fairly detailed. I will refer you to that documentation for more information.

The JEditorPane constructor

Listing 4 (p. 2056) calls an overloaded **JEditorPane** constructor that is described in the documentation as follows:

"Creates a JEditorPane based on a specified URL for input."

(**Note that there is another constructor** that would allow us to create the **JEditorPane** object passing a URL string to the constructor. Had I used that constructor, it wouldn't have been necessary to create the URL object. For illustration, I will use that constructor in a later program in this module.)

Documentation snippets

There are a couple of snippets from that documentation that are particularly important to this module. The first snippet is:

"Some kinds of content may provide hyperlink support by generating hyperlink events. The HTML EditorKit will generate hyperlink events if the JEditorPane is not editable (JEditorPane.setEditable(false); has been called)."

Since we are definitely interested in hyperlink events, Listing 4 (p. 2056) calls the **setEditable** method on the new **JEditorPane** object passing false as a parameter.

A second snippet that will be important later in this module reads:

"The setPage method can be used to initialize the component from a URL."

We will use this capability later to cause a hyperlink event handler to follow a link in a webpage when we click on the hyperlink.

Register a hyperlink listener

Listing 5 (p. 2056) uses standard Java event handling code to register a hyperlink listener object on the **JEditorPane** object. As I mentioned earlier, **this** object is suitable for use as a listener object.

Listing 5 - Register a hyperlink listener.

```

html.addHyperlinkListener(this);

```

Table 5.37

⁵³<http://docs.oracle.com/javase/7/docs/api/javax/swing/JEditorPane.html>

I will explain the hyperlink listener code shortly.

Display the JEditorPane

Listing 6 (p. 2057) uses standard Swing code to display the **JEditorPane** in a **JFrame** object. There is nothing new or interesting about this code so I won't discuss it further.

Listing 6 - Display the JEditorPane.

```

        this.getContentPane().add(html);
        this.setSize(669,669);
        this.setVisible(true);
    }//end if

    }catch(Exception e){
        e.printStackTrace();
    }//end catch
}//end constructor

```

Table 5.38

Listing 6 (p. 2057) also signals the end of the constructor for the class named **Java4655cHtmlHandler**

The event handler method

Listing 7 (p. 2057) shows the event handler method named **hyperlinkUpdate** in its entirety.

Listing 7 - The hyperlinkUpdate method.

```

    public void hyperlinkUpdate(HyperlinkEvent e) {
    if (e.getEventType() ==
        HyperlinkEvent.EventType.ENTERED){
        System.out.println("ENTERED");
    }else if (e.getEventType() ==
        HyperlinkEvent.EventType.EXITED){
        System.out.println("EXITED");
    }else if (e.getEventType() ==
        HyperlinkEvent.EventType.ACTIVATED){
        System.out.println("ACTIVATED");
    }//end if
    }//end hyperlinkUpdate method
//-----//

}//end class Java4655cHtmlHandler

```

Table 5.39

This hyperlink event handler simply displays the type of event on the command-line screen as the mouse pointer touches hyperlinks on the webpage. The possible types of events and the actions that cause them are as follows:

- ENTERED - touch a hyperlink with the mouse
- EXITED - move the mouse pointer away from a touched hyperlink
- ACTIVATED - click a hyperlink with the mouse

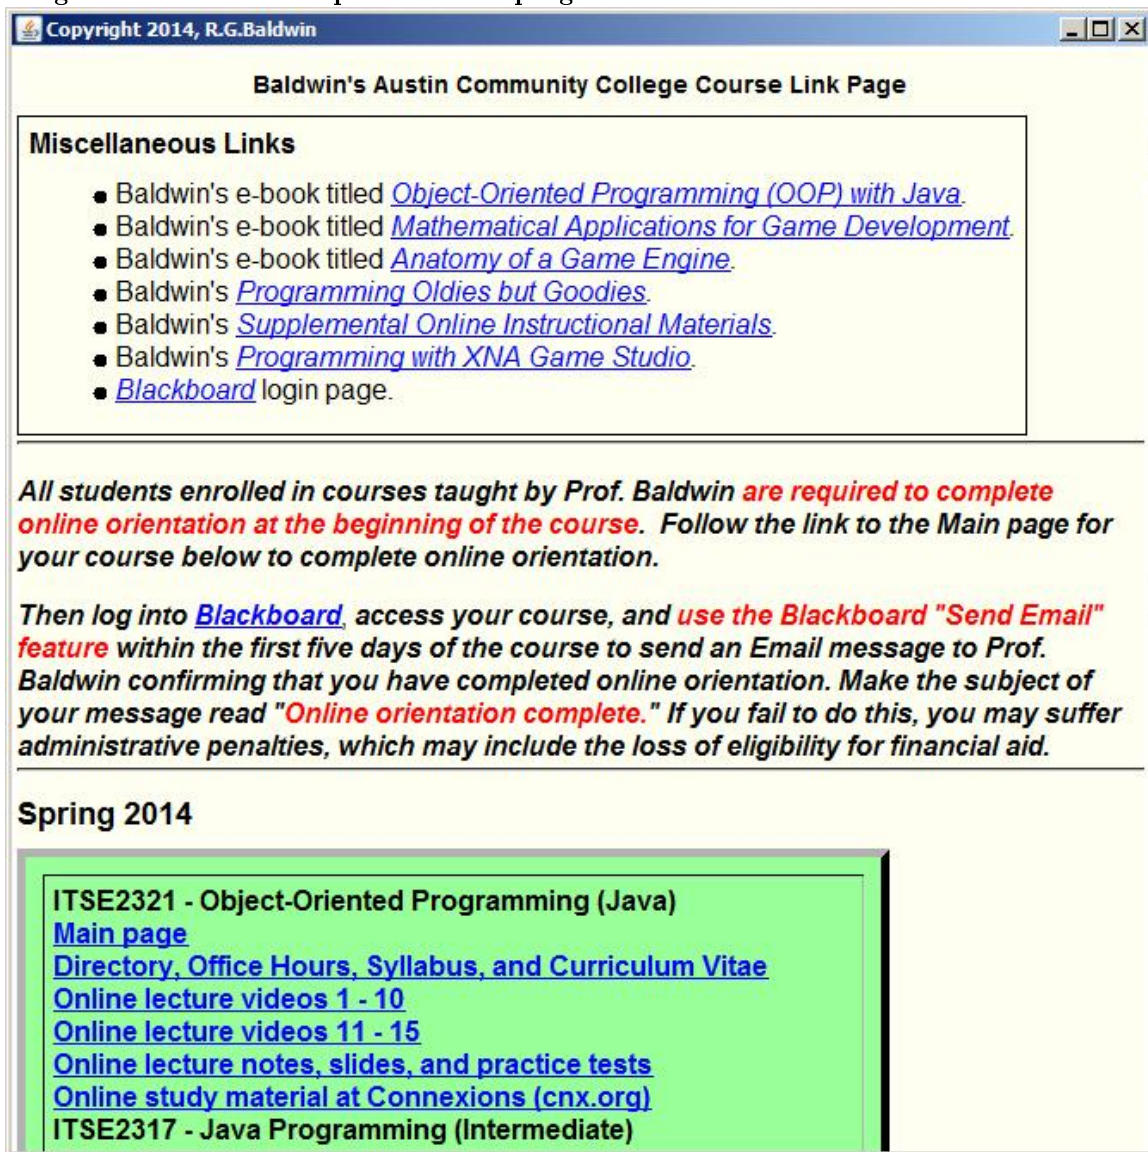

The code in Listing 7 (p. 2057) is straightforward and shouldn't require further explanation.

Listing 7 (p. 2057) also signals the end of the class named `Java4655cHtmlHandler`.

The program output

Figure 1 (p. 2058) shows the output that you should see if you compile and run this program. Note however that the content of this page changes each semester so you may see something a little different.

Figure 1 - JFrame output from the program named Java4655c.

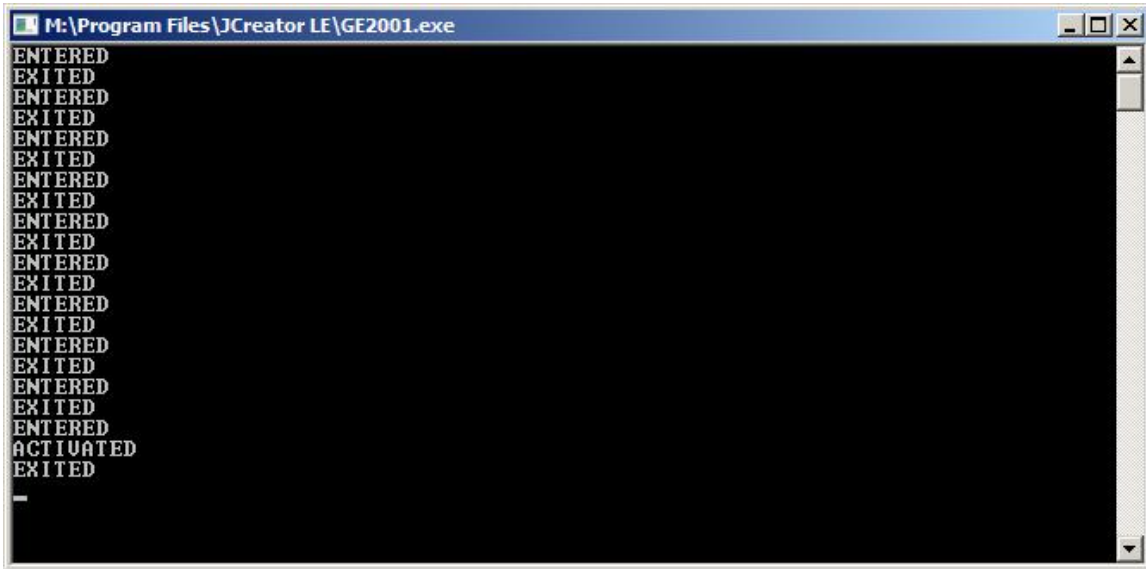

As I mentioned earlier, this program doesn't allow scrolling for web pages that are too large to fit in the `JEditorPane`. As you can see in Figure 1 (p. 2058), the webpage simply spills outside the viewing area. We will deal with that later in this module.

This program also doesn't support link following. If you touch or click a link, the code in Listing 7 (p. 2057) simply reports that fact on the command line screen. We will also deal with that later in this module.

Figure 2 (p. 2059) shows the result of moving the mouse around inside the hyperlinks in Figure 1 (p. 2058) and finally clicking on one of those links to create an ACTIVATED event.

Figure 2 - Command line output from the program named Java4655c.

```
M:\Program Files\JCreator LE\GE2001.exe
ENTERED

ENTERED
EXITED
ACTIVATED
EXITED
-
```

Now that you know the basics, we can put some meat on the skeleton.

5.2.10.3.2 The program named Java4655b

This program is similar to the previous program except that it allows you to follow hyperlinks. However, I will continue to defer scrolling until later in the module.

Once again, I will explain this program in fragments. However, rather than to explain the complete program, I will explain only those things that are significantly different from the previous program.

A complete listing of the program is provided in Listing 12 (p. 2067) .

The constructor for the Java4655bHtmlHandler class

Listing 8 (p. 2060) shows the beginning of the `Java4655bHtmlHandler` class including the entire constructor.

Listing 8 - The constructor for the Java4655bHtmlHandler class.

```
class Java4655bHtmlHandler extends JFrame
                                implements HyperlinkListener{
JEditorPane html;

//Constructor
public Java4655bHtmlHandler(String websiteString) {
    setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
    setTitle("Copyright 2014, R.G.Baldwin");

    try{
        if(websiteString != null) {
            html = new JEditorPane(websiteString);
            html.setEditable(false);
            html.addHyperlinkListener(this);

            this.getContentPane().add(html, BorderLayout.CENTER);
            this.setSize(669,669);
            this.setVisible(true);
        }//end if

    }catch(Exception e){
        e.printStackTrace();
    }//end catch
} //end constructor
```

Table 5.40**Differences from the previous program**

One difference between the code in Listing 8 (p. 2060) and the corresponding code in the previous program is that this version requires the website to be specified as a **String** instead of a URL (p. 2056) .

Another difference is that this version declares the **JEditorPane** reference as an instance variable to make it accessible to the **HyperlinkEvent** handler discussed below.

The HyperlinkEvent handler

Listing 9 (p. 2061) shows the **HyperlinkEvent** handler in its entirety.

Listing 9 - The HyperlinkEvent handler for Java4655b.

```

    public void hyperlinkUpdate(HyperlinkEvent e) {
    if (e.getEventType() ==
        HyperlinkEvent.EventType.ACTIVATED){
        //Ignore ENTERED and EXITED events and process only
        // ACTIVATED events.
        if (e instanceof HTMLFrameHyperlinkEvent) {
            //Ignore events in HTML frames
            System.out.println(
                "HTML Frame events are ignored");
        } else {
            try {
                //Display page defined by the HyperlinkEvent.
                html.setPage(e.getURL());
            } catch (Exception ex) {
                ex.printStackTrace();
            } //end catch
        } //end else
    } //end if
    } //end hyperlinkUpdate method

```

Table 5.41

This code makes it possible to follow links by clicking the hyperlinks in the HTML page that is displayed. Note that only ACTIVATED events are processed and even those events are not processed if they are contained in an HTML frame.

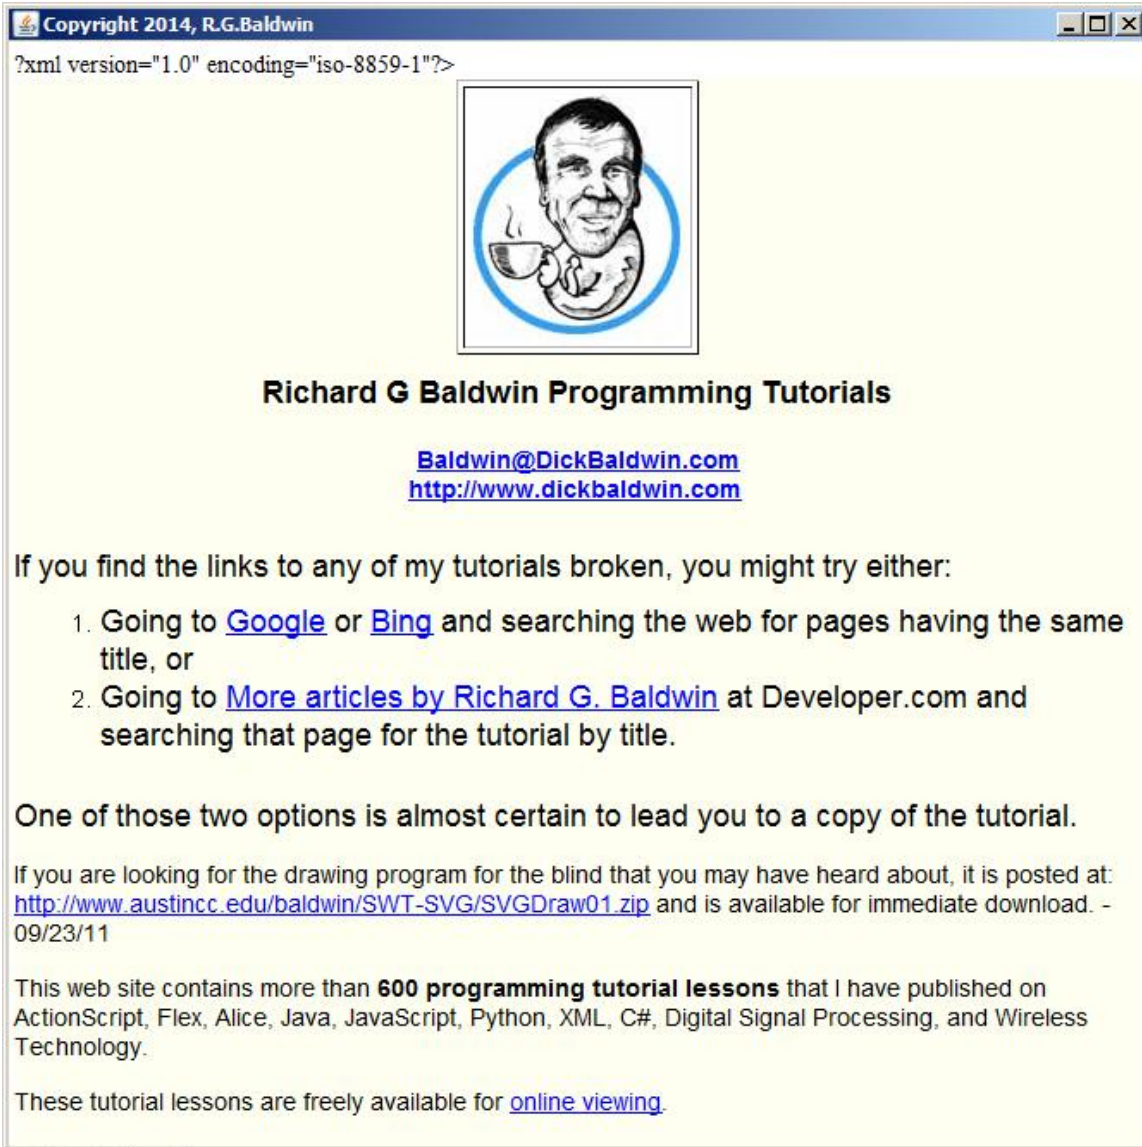

Following links

The code in Listing 9 (p. 2061) is straightforward. The statement that causes the program to follow links is the call to the **setPage** method passing a URL as a parameter. The documentation for this message reads *"Sets the current URL being displayed."*

The URL to be displayed is obtained by calling the **getURL** method on the incoming **HyperlinkEvent** object. The documentation for this method simply reads *"Gets the URL that the link refers to."*

As you can see, therefore, writing a simple browser that will access a web page and follow links is not difficult. The output from running this program is shown in Figure 3 (p. 2061) .

Figure 3 - JFrame output from the program named Java4655b.

Richard G Baldwin Programming Tutorials

Baldwin@DickBaldwin.com
<http://www.dickbaldwin.com>

If you find the links to any of my tutorials broken, you might try either:

1. Going to [Google](#) or [Bing](#) and searching the web for pages having the same title, or
2. Going to [More articles by Richard G. Baldwin](#) at Developer.com and searching that page for the tutorial by title.

One of those two options is almost certain to lead you to a copy of the tutorial.

If you are looking for the drawing program for the blind that you may have heard about, it is posted at: <http://www.austincc.edu/baldwin/SWT-SVG/SVGDraw01.zip> and is available for immediate download. - 09/23/11

This web site contains more than **600 programming tutorial lessons** that I have published on ActionScript, Flex, Alice, Java, JavaScript, Python, XML, C#, Digital Signal Processing, and Wireless Technology.

These tutorial lessons are freely available for [online viewing](#).

Scrolling

You should be able to run the program and follow the links from one page to the next. We are still missing something, however. If you click on a link to an anchor that is on the same page but not visible in the **JFrame**, nothing happens. This is because this version of the program is incapable of scrolling to and displaying that location on the page. Our next task will be to correct that issue.

5.2.10.3.3 The program named Java4655a

Scrolling code in Java4655a

Listing 13 (p. 2069) provides a complete listing of a program that incorporates scrolling. The only difference between this program and the previous program is shown in Listing 10 (p. 2063).

Listing 10 - Scrolling code in Java4655a.

```
        if(websiteString != null) {
        html = new JEditorPane(websiteString);
        html.setEditable(false);
        html.addHyperlinkListener(this);

        JScrollPane scroller = new JScrollPane();
        JViewport vp = scroller.getViewport();
        vp.add(html);
        this.getContentPane().add(
                                scroller, BorderLayout.CENTER);
        this.setSize(669,669);
        this.setVisible(true);
        }//end if
```

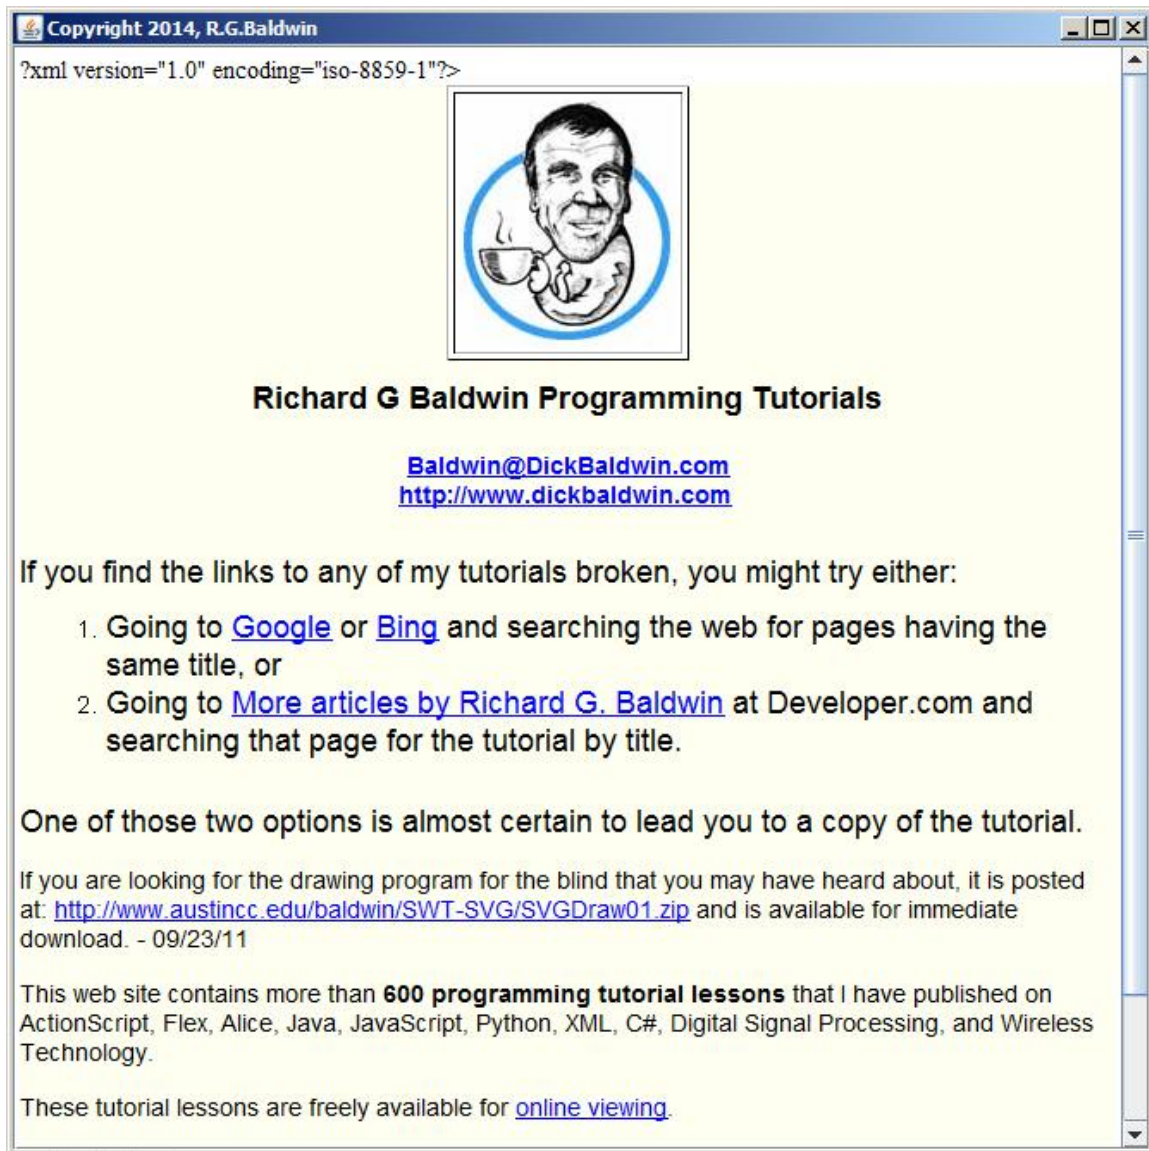

Table 5.42

The code in Listing 10 (p. 2063) that provides scrolling has nothing to do with network programming so I will leave it up to the student to find an explanation of this code somewhere else ⁵⁴ on the web.

Figure 4 (p. 2063) shows the initial output from running this program. Note the vertical scroll bar on the right side of the image.

Figure 4 - JFrame output from the program named Java4655a.

⁵⁴<http://docs.oracle.com/javase/tutorial/uiswing/components/scrollpane.html>

5.2.10.3.4 What's missing?

There are at least three features that we would need to add to turn this program into a simple but functional web browser.

- A way for the user to enter the website of interest and to change it at will.
- A "Back" button.
- A "Forward" button.

Adding these features is not particularly difficult, but I will leave it as an exercise for the student to add these features and convert this program into a functional web browser.

5.2.10.4 Run the program

I encourage you to copy the code from Listing 11 (p. 2065), Listing 12 (p. 2067), and Listing 13 (p. 2069). Compile the code and execute it. Experiment with the code, making changes, and observing the results of

your changes. Make certain that you can explain why your changes behave as they do.

5.2.10.5 What's next?

The next module will introduce sockets for network programming.

5.2.10.6 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java4655: A Rendering Web Browser

5.2.10.7 Complete program listing

Listing 11 - The program named Java4655c.

```
/*File Java4655c.java
Copyright 2014, R.G.Baldwin
Rev 01/07/14
```

This is a skeleton program that illustrates how to load a web page into a JEditorPane and illustrates how to identify the three types of hyperlink events:

```
ENTERED
EXITED
ACTIVATED
*****/

import javax.swing.*;
import javax.swing.event.*;
```

```

import javax.swing.text.html.*;
import java.net.*;
import java.awt.*;

class Java4655c{

    public static void main(String[] args){
        new Java4655c().runner(
            "http://www.austincc.edu/baldwin");
    }//end main
    //-----//

    void runner(String webSiteLink){
        try{
            //Create a new URL object from the website string
            URL website = new URL(webSiteLink);
            //Instantiate an overall web page handler
            new Java4655cHtmlHandler(website);
        }catch(Exception e){
            e.printStackTrace();
        }//end catch
    }//end runner
} //end class Java4655c
//=====//

class Java4655cHtmlHandler extends JFrame
    implements HyperlinkListener{

    //Constructor
    public Java4655cHtmlHandler(URL website) {
        setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);

        setTitle("Copyright 2014, R.G.Baldwin");

        try{
            if(website != null) {
                //Create a JEditorPane containing the web page.
                JEditorPane html = new JEditorPane(website);
                html.setEditable(false);

                //Register a listener to listen for hyperlink
                // events.
                html.addHyperlinkListener(this);

                //Display the JEditorPane
                this.getContentPane().add(html);
                this.setSize(669,669);
                this.setVisible(true);
            }//end if

        }catch(Exception e){

```

```

        e.printStackTrace();
    }//end catch
} //end constructor
//-----//

//This hyperlink event listener simply displays the
// type of event on the command-line screen.
public void hyperlinkUpdate(HyperlinkEvent e) {
    if (e.getEventType() ==
        HyperlinkEvent.EventType.ENTERED){
        System.out.println("ENTERED");
    }else if (e.getEventType() ==
        HyperlinkEvent.EventType.EXITED){
        System.out.println("EXITED");
    }else if (e.getEventType() ==
        HyperlinkEvent.EventType.ACTIVATED){
        System.out.println("ACTIVATED");
    } //end if
} //end hyperlinkUpdate method
//-----//

} //end class Java4655cHtmlHandler

```

Listing 12 - The program named Java4655b.

```

/*File Java4655b.java
Copyright 2014, R.G.Baldwin
Rev 01/05/14

```

This is a simple web browser that can follow links.

Uses website string to create JEditPane object.

Ignores ENTERED and EXITED hyperlink events. Uses
ACTIVATED events to follow links.

Ignores links in HTML frames.

```

*****/

import javax.swing.*;
import javax.swing.event.*;
import javax.swing.text.html.*;

5.2.11.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX. More specifically, it is one in a sub-collection of modules designed for teaching network programming in that course. The purpose of this module is to introduce the student to the **Socket** class.

5.2.11.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.2.11.2.1.1 Figures

- Figure 1 (p. 2074) . Successful daytime query.
- Figure 2 (p. 2075) . Output for a successful echo test.
- Figure 3 (p. 2078) . Daytime program output.
- Figure 4 (p. 2081) . Output from the simple browser program.

5.2.11.2.1.2 Listings

- Listing 1 (p. 2075) . Beginning of the program named Java4660a.
- Listing 2 (p. 2075) . Instantiate a Socket object.
- Listing 3 (p. 2076) . Get I/O stream objects.
- Listing 4 (p. 2076) . Send a line of text to the server and display the echo.
- Listing 5 (p. 2077) . Beginning of the program named Java4660b.
- Listing 6 (p. 2078) . Get an input stream.
- Listing 7 (p. 2078) . Read and display incoming data.

5.2.11.3 General background information

Sockets in Java come in at least three varieties that are implemented by the following Java classes

- **Socket**
- **DatagramSocket**
- **ServerSocket**

The first two socket classes represent **TCP** and **UDP** communications respectively.

Generally, these two socket classes are used to implement both clients and servers, while the **ServerSocket** class is only used to implement servers.

This module will concentrate on the use of the **Socket** class. The **DatagramSocket** class will be covered a future module. In the meantime, you can read about the **DatagramSocket** class and other interesting topics in my earlier publications at:

- Network Programming - Server Sockets ⁵⁶
- Network Programming - Datagram Clients ⁵⁷
- Network Programming - Datagram Servers ⁵⁸
- Network Programming - Stubs, Skeletons, and Remote Objects ⁵⁹
- Wireless Home Security and Java ⁶⁰

In addition, you may find a great deal of useful information in my older publications that are accessible at Programming Oldies But Goodies ⁶¹ .

A low-level mechanism

Socket programming provides a low-level mechanism by which you can connect two computers for the exchange of data. One of those is generally considered to be the *client* while the other is considered to be the *server* .

The *client* initiates a connection with a *server*. *Servers* wait for a *clients* to initiate connections.

A mutually acceptable application protocol

The governing protocol will determine what happens after the connection is made. In order for two computers to communicate effectively, they must each implement some mutually acceptable application protocol.

Data flow

Socket programming makes it possible for you to cause data to flow in a full-duplex mode between a *client* and a *server* . This data flow can be viewed in almost exactly the same way that we view data flow to and from a disk: as a stream of bytes.

As with most stream data processing, the system is responsible for moving the bytes from the source to the destination. It is the responsibility of the programmer to assign meaning to those bytes.

An application protocol

Assigning meaning takes on a special significance for socket programming. In particular, as mentioned above, it is the responsibility of the programmer to implement a mutually acceptable communication protocol,

⁵⁶<http://cnx.org/content/m45602/latest/Java562.htm>

⁵⁷<http://cnx.org/content/m45602/latest/Java564.htm>

⁵⁸<http://cnx.org/content/m45602/latest/Java566.htm>

⁵⁹<http://cnx.org/content/m45602/latest/Java568.htm>

⁶⁰<http://cnx.org/content/m45605/latest/Java734.htm#Sockets15>

⁶¹<http://cnx.org/content/col11478/latest/>

at the application level, to cause the data to flow in an orderly manner. Some of the bytes are used to implement the protocol, and some of the bytes are used to transfer data.

An application protocol is a set of rules by which the programs in the two computers can carry on a conversation and transfer data in the process.

The HTTP protocol

For example, we will write a very abbreviated form of the HTTP protocol to download a web page from a server and to display it as raw text.

This program will involve adherence to a fairly simple protocol. (*At least the part that we implement will be simple.*)

The daytime protocol

We will also write a program that obtains the date and time from the same or another computer. In this case, the protocol is about as simple as it can possibly be. The client will simply make the connection and listen for a string containing the date and time. In this case, the client isn't even required to make a request.

The echo protocol

We will write another program that sends a line of text to a computer and receives an echo of that text. This protocol is only slightly more complicated than the daytime protocol in that it is necessary to send text to the other computer in order to elicit a response.

The application protocol is the hard part

It is easy to use sockets to write code that will cause a stream of bytes to flow in both directions between a *client* and a *server*. This is no more difficult than causing a stream of bytes to flow in both directions between memory and a file on a disk.

Getting the bytes to flow is the easy part. Beyond that, you must do all of the programming to implement an application protocol that is understood by both the *client* and the *server*. Often that is the more difficult part.

5.2.11.4 Discussion and sample code

5.2.11.4.1 Simple TCP/IP services

This discussion applies to the Windows operating system only. If you are using a different operating system you will need to do the necessary research to translate this information for use with your operating system.

See [Windows 7 Simple TCP/IP Services - What and How?](#)⁶² for more detailed information on this topic.

A simple server

Windows and some other operating systems make it possible to cause a computer to act as a simple server to deliver the following services:

- **Echo on port 7**
- Daytime on port 13
- Quote of the Day on port 17
- Character generator on port 19
- Discard on port 9

This module will be concerned with only the first two. However, to use any of them, you must configure your computer to support all of them.

Configuring your computer

Do the following to configure your computer to support these services.

In Windows 7, Vista, and possibly older versions of the Windows operating system, do the following:

- **Open the Control Panel**
- Select Programs and Features

⁶²<http://www.window networking.com/articles-tutorials/windows-7/Windows-7-Simple-TCP-IP-Services-What-How.html>

- Select Turn Windows features on or off
- Scroll down to Simple TCP/IP services and check the box
- Also check the box for Telnet Client
- Click OK and follow the directions

On some computers, this may take a long time to complete. (*It took more than 15 minutes on an older laptop computer that I own.*) .

Test using telnet

When the process is complete, open a command line window and enter the following:

```
telnet localhost 13
```

You should see something like the contents of Figure 1 (p. 2074) if your computer is supporting simple TCP/IP services.

Figure 1 - Successful daytime query.
<pre>5:27:30 PM 1/10/2014 Connection to host lost.</pre>

Table 5.43

You can use localhost to do a query on the same machine or you can do a query on the name of some other *properly configured* computer on a local area network.

(*You can also use the name of the same computer in place of localhost to do a query on the same computer.*)

Opening ports on the firewall

In the case of accessing another computer on the network, in addition to the procedure described above (p. 2073) , you may also need to open the required ports in the Windows firewall or perhaps a firewall that is being managed by other software running on that computer.

(*The ports of interest are shown in the above list (p. 2073) .*)

I won't attempt to explain how to open and close ports in the firewall. The Windows *Help and Support* feature explains how to open and close ports in the Windows firewall. If the firewall is being managed by another program, the documentation for that program should explain how to open and close ports.

5.2.11.4.2 Echo program

This program implements a client that performs a simple echo test by sending a line of text to the echo port (*port 7*) on a server (*or on the same computer*) .

Overview

The program begins by instantiating a **String** object containing the name of an echo server that is being used to test the program (*localhost as the program is shown in Listing 1 (p. 2075)*) . This is followed by the declaration and initialization of an **int** variable containing the standard echo port number (*7*) .

Then the program gets a socket connection to port 7 on the server as shown in Listing 2 (p. 2075) ..

Following this, the program gets input and output streams from the socket and wraps them in the **Reader** and **Writer** classes as shown in Listing 3 (p. 2076) .

Once the connection is made and the input and output streams are ready to use, the program sends a line of text to the echo port on the specified server as shown in Listing 4 (p. 2076) . This causes the server to send the same line of text back to the client.

The program reads the line of text that is received and displays it in the command-line window.

Finally, the program closes the socket and terminates.

The program output

Assuming that you select a computer that supports echo processing on port 7, the output from this program should be as shown in Figure 2 (p. 2075) .

Figure 2 - Output for a successful echo test.
echo: This is an echo test

Table 5.44

Beginning of the program named Java4660a

I will discuss this program in fragments. (*I will ignore exception handling code.*) A complete listing of the program is provided in Listing 12 (p. 2082) . The beginning of the program is shown in Listing 1 (p. 2075) .

Listing 1 - Beginning of the program named Java4660a.
<pre> import java.net.*; import java.io.*; import java.util.*; class Java4660a{ public static void main(String[] args){ String server = "localhost"; int port = 7; //echo port </pre>

Table 5.45

Listing 1 (p. 2075) declares and initializes two local variables to specify the server and the port. We will use these variables later.

Instantiate a Socket object

Listing 2 (p. 2075) shows the key statement in this program insofar as learning new material is concerned.

Listing 2 - Instantiate a Socket object.
<i>continued on next page</i>

```
Socket socket = new Socket(server,port);
```

Table 5.46

The statement in Listing 2 (p. 2075) establishes a connection with the specified port on the specified server by instantiating a new object of type **Socket** .

Once this object exists, it is possible to use it to communicate with the server on the specified port using the protocol prescribed for the service being delivered on that port.

The constructor for this class throws two different types of exceptions so you will need to wrap this statement in a try/catch block. The two types of exceptions are:

- **UnknownHostException**
- **IOException**

Get I/O stream objects

Once you have a **Socket** object, you can use that object to open input and output streams that allow you to transfer data between the client and the server using the code shown in Listing 3 (p. 2076) .

Listing 3 - Get I/O stream objects.

```
BufferedReader inputStream =
    new BufferedReader(new InputStreamReader(
        socket.getInputStream()));

PrintWriter outputStream =
    new PrintWriter(new OutputStreamWriter(
        socket.getOutputStream()),true);
```

Table 5.47

Note that the **true** parameter in the last line of Listing 3 (p. 2076) causes the output stream to flush automatically. Proper flushing is an important aspect of socket programming.

Send a line of text to the server and display the echo

The code in Listing 4 (p. 2076) uses the **outputStream** created above to send a line of text to the server, and then uses the **inputStream** created above to capture and display the echo that is returned from the server.

Listing 4 - Send a line of text to the server and display the echo.

```
//Send line of text to the server
outputStream.println("This is an echo test");
//Get echoed line back from server and display it
System.out.println("echo: "+inputStream.readLine());

//Close the socket
socket.close();
```

Table 5.48

Then Listing 4 (p. 2076) closes the socket.

You can view the remainder of the program in Listing 12 (p. 2082) .

The essence of socket programming

That's really about all there is to socket programming from the *client* viewpoint.

Beyond this, the programming complexity associated with socket programming results from the requirement to implement an application protocol that will successfully communicate with the server.

5.2.11.4.3 Date/time program

This program implements a *client* that gets the date and time from the *daytime* port (13) on a server that supports that port.

This program is even simpler than the previous one, because it isn't necessary to send anything to the server to get the desired result. All that is necessary to cause the server to send the information is to make the connection.

This program gets and displays the date and time on the server at " **localhost** ". However, you can modify the program to access another computer in your network if you choose to do so. It is not likely that you will find a server on the Internet at large that still supports the *daytime* port, but you can try.

The program also displays the current date and time in Austin, TX (*or wherever the program happens to be run*) for comparison.

Beginning of the program named Java4660b

As usual, I will explain this program in fragments. A complete listing is provided in Listing 13 (p. 2083)

As shown in Listing 5 (p. 2077) , program begins by instantiating a **String** object containing the name of the server being used to test the program.

Listing 5 - Beginning of the program named Java4660b.

```
import java.net.*;
import java.io.*;
import java.util.*;

class Sockets04{
    public static void main(String[] args){
        String server = "localhost";
        int port = 13; //daytime port

        try{
            //Get a socket, connected to the specified server
            // on the specified port.
            Socket socket = new Socket(server,port);
```

Table 5.49

This is followed by the declaration and initialization of an **int** variable identifying the standard *daytime* port: port 13.

Then the program gets a socket connection to port 13 on the specified server.

Get an input stream

Following this, the program gets an input stream from the socket and wraps it in the reader classes as shown in Listing 6 (p. 2078) .

Listing 6 - Get an input stream.

```
//Get an input stream from the socket
BufferedReader inputStream =
    new BufferedReader(new InputStreamReader(
        socket.getInputStream()));
```

Table 5.50

This program doesn't need an output stream because the client doesn't send anything to the server. As mentioned earlier, simply connecting is sufficient to trigger the server to send the date and time.

Read and display incoming data

After the connection is made via the socket and the input stream is ready to use, the client reads a line of incoming text as shown in Listing 7 (p. 2078) . This line of text contains the date and time sent by the server.

Listing 7 - Read and display incoming data.

```
System.out.println("Current time at " + server);
System.out.println(inputStream.readLine());
System.out.println("Current time in Austin, TX:");
System.out.println(new Date());

//Close the socket
socket.close();
```

Table 5.51

Daytime program output

The program displays this line of text, and also gets and displays the date and time on the local system using the **Date** class for comparison.

Figure 3 (p. 2078) shows the output for one run of the program.

Figure 3 - Daytime program output.

```
Current time at localhost
8:29:56 AM 1/12/2014
Current time in Austin, TX:
Sun Jan 12 08:29:56 CST 2014
```

Table 5.52

Then the program closes the socket and terminates.

5.2.11.4.4 Simple browser program

The next program is an extremely simple web browser program. More correctly, the next program is a simple HTTP client implemented using sockets. A complete listing of the program is provided in Listing 14 (p. 2084).

The program implements just enough of the HTTP protocol to make it capable of getting a file from an HTTP server. Considerably more programming effort would be required to turn it into a useful browser.

Beginning of the program named Java4660c

As shown in Listing 8 (p. 2079), the program begins by defining the name of a server and the number of the HTTP port on that server. Although the standard port number for HTTP servers is port 80, this program is written to access a Tomcat server as localhost using port 8080.

Listing 8 - Beginning of the program named Java4660c.

```
import java.net.*;
import java.io.*;

class Java4660c{
    public static void main(String[] args){
        String server = "localhost";
        int port = 8080; //http port on localhost
        try{
            //Get a socket, connected to the specified server
            // on the specified port.
            Socket socket = new Socket(server,port);
```

Table 5.53

Then the program opens a socket to the specified server on the specified port.

Create input and output streams

As shown in Listing 9 (p. 2079), the program creates input and output stream objects for transferring data between the *client* and the *server*.

Listing 9 - Create input and output streams.

```
        //Get an input stream from the socket
        BufferedReader inputStream =
            new BufferedReader(new InputStreamReader(
                socket.getInputStream()));

        //Get an output stream to the socket. Note
        // that this stream will autoflush.
        PrintWriter outputStream =
            new PrintWriter(new OutputStreamWriter(
                socket.getOutputStream()),true);
```

Table 5.54

The output stream will *autoflush* , which is critical. If the output stream isn't flushed, the server will not respond properly. (*Presumably it may not receive all of the data until the stream is flushed.*)

Send a GET command

The HTTP protocol provides several different commands or requests that the client can send to the server. This program implements only the **GET** command. This is a request by the client to find and download a specified file.

Then, as shown in Listing 10 (p. 2080) , acting as an HTTP client, the program sends a **GET** command to the server specifying a particular path and file name. The **GET** command is part of the HTTP application protocol.

Listing 10 - Send a GET command.

```
outputStream.println("GET /Java4570b.jsp");
```

Table 5.55

Fetch and send

This causes the server to attempt to fetch the specified file and send it to the client. If the server is being properly supported on the specific port, it will send something, although that something could be an error message.

Note that the request includes not only the file name, but also the path to that file relative to the directory that the HTTP server software considers to be the *pseudo-root* . This is probably not the actual root directory on the server computer, but rather is a logical root.

The server software is willing to access and deliver files from directories relative to this *pseudo-root* .

Note that the request is actually made by printing a line of text on the stream that is connected to the server.

Read and display text from the server

Finally as shown in Listing 11 (p. 2080) , the program reads lines of text from the input stream and displays them on the standard output device.

Listing 11 - Read and display text from the server.

```
//Declare a String to read lines into.
String line = null;

//Loop reading and displaying lines until null
// is received.
while((line = inputStream.readLine()) != null)
    System.out.println(line);

//Close the socket
socket.close();
```

Table 5.56

Output from the simple browser program

In this particular case, the output was as shown in Figure 4 (p. 2081) .

Figure 4 - Output from the simple browser program.

```

    <html>
<head><title>Java4570b</title></head>
<body>

<form method='get'
  action='http://localhost:8080/Java4570b.jsp'>
  <p>Enter a name and press the button</p>
  <p>Name: <input type='text' name='firstName' /></p>
  <input type='submit' value='Submit Name' />

<br/><br/>Your session ID and list of names is:<br/>
Empty<br/>

</form></body></html>

```

Table 5.57**A curious result**

The requested file was a JSP file consisting of JSP tags embedded in HTML code. Curiously, only the HTML code was returned by the server. (*I suppose it is also possible that the JSP tags were returned but were not displayed by the program for some reason.*)

In any event, I will leave it as an exercise for those students who may be interested to research the matter. As I mentioned earlier:

"Getting the bytes to flow is the easy part. Beyond that, you must do all of the programming to implement an application protocol that is understood by both the client and the server . Often that is the more difficult part."

When there are no more lines to be read, a null is received. This causes the client to exit the input loop and to close the socket.

5.2.11.5 Run the programs

I encourage you to copy the code from Listing 12 (p. 2082) , Listing 13 (p. 2083) , and Listing 14 (p. 2084) . Compile the code and execute it. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

5.2.11.6 Miscellaneous

This section contains a variety of miscellaneous information.

5.2.11.7 Complete program listings

Listing 12 - The program named Java4660a.

```
/*File Java4660a.java Copyright 1998, R.G.Baldwin
Revised 01/10/14
```

This program performs a simple echo test with localhost by sending a line of text to the echo port, port 7.

The computer must have been previously configured to support the echo port.

The output from this program is:

```
echo: This is an echo test
*****/
```

```
import java.net.*;
import java.io.*;
import java.util.*;

class Java4660a{
    public static void main(String[] args){
        String server = "localhost";
        int port = 7; //echo port

        try{
            //Get a socket, connected to the specified server
            // on the specified port.
            Socket socket = new Socket(server,port);
```

```

//Get an input stream from the socket
BufferedReader inputStream =
    new BufferedReader(new InputStreamReader(
        socket.getInputStream()));

//Get an output stream to the socket. Note
// that this stream will autoflush.
PrintWriter outputStream =
    new PrintWriter(new OutputStreamWriter(
        socket.getOutputStream()),true);

//Send line of text to the server
outputStream.println("This is an echo test");
//Get echoed line back from server and display it
System.out.println("echo: "+inputStream.readLine());

//Close the socket
socket.close();
} //end try
catch(Exception e){
    e.printStackTrace();
} //end catch
} //end main
} //end class Java4660a

```

Listing 13 - The program named Java4660b.

```

/*File Sockets04.java Copyright 1998, R.G.Baldwin
Revised 01/10/14

```

This program gets and displays the date and time on the server at "localhost".

It also displays the current date and time in Austin, TX, or wherever the program happens to be run.

The computer must have been previously configured to support the daytime port.

One output from this program was:

```

Current time at localhost
2:39:55 PM 1/10/2014
Current time in Austin, TX:
Fri Jan 10 14:39:55 CST 2014
*****/

```

```

import java.net.*;
import java.io.*;
import java.util.*;

class Sockets04{

```

```

public static void main(String[] args){
    String server = "localhost";
    int port = 13; //daytime port

    try{
        //Get a socket, connected to the specified server
        // on the specified port.
        Socket socket = new Socket(server,port);

        //Get an input stream from the socket
        BufferedReader inputStream =
            new BufferedReader(new InputStreamReader(
                socket.getInputStream()));

        System.out.println("Current time at " + server);
        System.out.println(inputStream.readLine());
        System.out.println("Current time in Austin, TX:");
        System.out.println(new Date());

        //Close the socket
        socket.close();
    }//end try
    catch(Exception e){
        e.printStackTrace();
    }//end catch UnknownHostException
    }//end main
} //end class Sockets04

```

Listing 14 - The program named Java4660c.

```

/*File Java4660c.java Copyright 1998, R.G.Baldwin
Revised 01/10/14

```

This program is a simple http client (web browser) implemented using sockets.

The program implements just enough of the http protocol to make it capable of getting an html page from an http server.

The program, acting as an http client, sends a GET command to the server specifying a particular path and file name.

The server is a Tomcat server operating as localhost on port 8080.

As of 01/10/14, the output from this program was as follows.

```

<html>
<head><title>Java4570b</title></head>

```

```

<body>

<form method='get'
  action='http://localhost:8080/Java4570b.jsp'>
  <p>Enter a name and press the button</p>
  <p>Name: <input type='text' name='firstName' /></p>
  <input type='submit' value='Submit Name' />

<br/><br/>Your session ID and list of names is:<br/>

Empty<br/>

</form></body></html>
*****/

import java.net.*;
import java.io.*;

class Java4660c{
  public static void main(String[] args){
    String server = "localhost";
    int port = 8080; //http port on localhost
    try{
      //Get a socket, connected to the specified server
      // on the specified port.
      Socket socket = new Socket(server,port);
      //Get an input stream from the socket
      BufferedReader inputStream =
        new BufferedReader(new InputStreamReader(
          socket.getInputStream()));

      //Get an output stream to the socket. Note
      // that this stream will autoflush.
      PrintWriter outputStream =
        new PrintWriter(new OutputStreamWriter(
          socket.getOutputStream()),true);

      //Send a GET command to the server
      outputStream.println("GET /Java4570b.jsp");

      //Declare a String to read lines into.
      String line = null;

      //Loop reading and displaying lines until null
      // is received.
      while((line = inputStream.readLine()) != null)
        System.out.println(line);
    }
  }
}

```

```
        //Close the socket
        socket.close();
    }//end try
    catch(Exception e){
        e.printStackTrace();
    }//end catch
    }//end main
} //end class Java4660c
//=====//

-end-
```

5.2.12 Java4660r-Review⁶³

5.2.12.1 Table of Contents

- Preface (p. 2087)
- Questions (p. 2087)
 - 1 (p. 2087) , 2 (p. 2087) , 3 (p. 2087) , 4 (p. 2087) , 5 (p. 2088)
- Answers (p. 2089)
- Miscellaneous (p. 2090)

5.2.12.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX.

This module contains review questions and answers keyed to the module titled Java4660: Sockets⁶⁴ in the Network Programming sub-collection.

Once you study that module, you should be able to answer the review questions in this module.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

5.2.12.3 Questions

5.2.12.3.1 Question 1

True or False?

Sockets in Java come in at least three varieties that are implemented by the following Java classes

- **Connector**
- **DatagramConnector**
- **ServerConnector**

Go to answer 1 (p. 2090)

5.2.12.3.2 Question 2

True or False?

The **Socket** and **DatagramSocket** classes represent **TCP** and **UDP** communications respectively.

Go to answer 2 (p. 2089)

5.2.12.3.3 Question 3

True or False?

Generally, the **ServerSocket** class is used to implement both clients and servers, while the **Socket** and **DatagramSocket** classes are only used to implement servers

Go to answer 3 (p. 2089)

5.2.12.3.4 Question 4

True or False?

Socket programming provides a low-level mechanism by which you can connect two computers for the exchange of data.

Go to answer 4 (p. 2089)

⁶³This content is available online at <<http://cnx.org/content/m49571/1.3/>>.

⁶⁴<http://cnx.org/content/m49539/latest/?collection=col11441/latest>

5.2.12.3.5 Question 5

True or False?

Socket programming makes it possible for you to cause data to flow in a full-duplex mode between a *client* and a *server* . This data flow can be viewed in almost exactly the same way that we view data flow to and from a disk: as a stream of bytes.

Go to answer 5 (p. 2089)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.2.12.4 Answers

5.2.12.4.1 Answer 5

True.

Go back to Question 5 (p. 2088)

5.2.12.4.2 Answer 4

True.

Go back to Question 4 (p. 2087)

5.2.12.4.3 Answer 3

False. Generally, the **Socket** and **DatagramSocket** classes are used to implement both clients and servers, while the **ServerSocket** class is only used to implement servers

Go back to Question 3 (p. 2087)

5.2.12.4.4 Answer 2

True.

Go back to Question 2 (p. 2087)

5.2.12.4.5 Answer 1

False. Sockets in Java come in at least three varieties that are implemented by the following Java classes

- **Socket**
- **DatagramSocket**
- **ServerSocket**

Go back to Question 1 (p. 2087)

5.2.12.5 Miscellaneous

5.3 Search Engines

5.3.1 Java4585: Getting Started with Search Engines⁶⁵

5.3.1.1 Table of Contents

- Preface (p. 2091)
- Servlets, search engines, or JSON (p. 2091)
- Search engines (p. 2091)
- Miscellaneous (p. 2091)

⁶⁵This content is available online at <<http://cnx.org/content/m55646/1.3/>>.

5.3.1.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX. The purpose of this module is to get you started with Search Engines.

5.3.1.3 Servlets, search engines, or JSON

As explained in the page titled Java4510: Preface to INEW 2338 ⁶⁶, only one of the topics *Search Engines*, *Servlets*, or *JSON* is covered in the course in any particular semester. However, all three are important. The course material in the Blackboard course management program indicates which topic is covered in the current semester.

Students are encouraged to study all three topics for their own educational purposes in order to enhance their prospects of landing a job as a Java programmer.

5.3.1.4 Search engines

An understanding of search engines is a valuable skill for a programming student to acquire. Furthermore, it is practical for an instructor to assess a student's understanding of and ability to develop a web search engine written in Java. This assessment can be based solely on practical programming assignments along with a written test.

The search-engine assignments can be written and tested on any computer capable of running the Java Standard Edition development kit (*including the computers in the on-campus labs*) with no requirement to install any special software.

The ability to develop a rudimentary search engine doesn't require any knowledge of Java programming beyond that which the student should already have acquired in this and the prerequisite courses. However, it does require the student to do independent research into the syntax and structure of HTML web pages and to combine that knowledge with prior knowledge of Java programming. Thus, this search-engine competency requirement tests the student's ability to apply prior Java programming knowledge to a very useful real-world scenario – search engines.

Students will be provided the source code for a rudimentary Java web crawler that can be used as a starting point for the development of the search engine required for each assignment. Students who have completed the prerequisite courses should have no difficulty understanding the code in that program. It will be the responsibility of the student to modify and upgrade the web crawler program in such a way as to satisfy the specifications for each programming assignment.

Students will also be provided links to several online search-engine resources along with review questions and answers for use in preparing for the written test.

5.3.1.5 Miscellaneous

This section contains a variety of miscellaneous information.

5.3.2 Java4590r-Review for search engines⁶⁷

5.3.2.1 Table of contents

- Preface (p. 2093)
- Questions (p. 2093)
 - 1 (p. 2093) , 2 (p. 2093) , 3 (p. 2093) , 4 (p. 2093) , 5 (p. 2094) , 6 (p. 2094) , 7 (p. 2094) , 8 (p. 2094) , 9 (p. 2094) , 10 (p. 2094) , 11 (p. 2094) , 12 (p. 2094) , 13 (p. 2095) , 14 (p. 2095) , 15 (p. 2095)
- Answers (p. 2096)
- Miscellaneous (p. 2098)

5.3.2.2 Preface

This module is one in a collection of modules designed for teaching *INEW2338 Advanced Java Programming* at Austin Community College in Austin, TX.

This module contains review questions and answers on *search engines* along with hyperlinks to online material from which those questions and answers were derived.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

5.3.2.3 Questions

5.3.2.3.1 Question 1

True or False? The **robots lockout standard** , also known as the **robots lockout protocol** or **robots.txt protocol** , is a standard used by websites to communicate with web crawlers and other web robots.

Go to answer 1 (p. 2098)

5.3.2.3.2 Question 2

True or False? The **robots exclusion standard** specifies the instruction format to be used to inform the robot about which areas of the website should not be processed or scanned.

Go to answer 2 (p. 2098)

5.3.2.3.3 Question 3

True or False? All robots cooperate with the **robots exclusion standard** including email harvesters, spambots and malware robots that scan for security vulnerabilities.

Go to answer 3 (p. 2098)

5.3.2.3.4 Question 4

True or False? When a site owner wishes to give instructions to web robots they place a text file called **robots.txt** in the root of the web site hierarchy (e.g. <https://www.example.com/robots.txt>). This text file contains the instructions in a specific format. Robots that choose to follow the instructions try to fetch this file and read the instructions before fetching any other file from the web site. If this file doesn't exist, web robots assume that the web owner wishes to provide no specific instructions, and crawl the entire site.

Go to answer 4 (p. 2098)

⁶⁷This content is available online at <<http://cnx.org/content/m55520/1.1/>>.

5.3.2.3.5 Question 5

True or False? Marking an area of a site "out of bounds" with `robots.txt` guarantees exclusion of all web robots.

Go to answer 5 (p. 2098)

5.3.2.3.6 Question 6

True or False? To cause a webpage to perform better in search engine listings, the most important content should be in Flash files.

Go to answer 6 (p. 2097)

5.3.2.3.7 Question 7

True or False? Search engines have two major functions:

1. crawling and building an index, and
2. providing search users with a ranked list of the websites they've determined are the most relevant.

Go to answer 7 (p. 2097)

5.3.2.3.8 Question 8

True or False? The link structure of the web serves to bind all of the pages together. Links allow the search engines' automated robots, called "crawlers" or "spiders," to reach the many billions of interconnected documents on the web. Once the engines find these pages, they decipher the code from them and store selected pieces in massive databases, to be recalled later when needed for a search query.

Go to answer 8 (p. 2097)

5.3.2.3.9 Question 9

True or False? *Search Engine Optimization (SEO)* is the process of affecting the visibility of a website or a web page in a search engine's unpaid results - often referred to as "natural," "organic," or "earned" results.

Go to answer 9 (p. 2097)

5.3.2.3.10 Question 10

True or False? When a person performs an online search, the search engine begins crawling the web and returning a list of all connected hyperlinks that are encountered.

Go to answer 10 (p. 2097)

5.3.2.3.11 Question 11

True or False? Search engines typically assume that the more popular a site, page, or document, the more valuable the information it contains must be

Go to answer 11 (p. 2097)

5.3.2.3.12 Question 12

True or False? The prototype for the Google search engine was developed at MIT.

Go to answer 12 (p. 2097)

5.3.2.3.13 Question 13

True or False? One of the main contributions to improved search engine performance, developed by Brin and Page, was **PageRank** .

Go to answer 13 (p. 2096)

5.3.2.3.14 Question 14

True or False? **PageRank** is an algorithm used by Google Search to rank websites in their search engine results. PageRank was named after Larry Page, one of the founders of Google. PageRank is a way of measuring the importance of website pages. According to Google: PageRank works by counting the number and quality of links to a page to determine a rough estimate of how important the website is. The underlying assumption is that more important websites are likely to receive more links from other websites

Go to answer 14 (p. 2096)

5.3.2.3.15 Question 15

True or False? **PageRank** is the only algorithm used by Google to order search engine results.

Go to answer 15 (p. 2096)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.3.2.4 Answers

5.3.2.4.1 Answer 15

False. **PageRank** is not the only algorithm used by Google to order search engine results, but it is the first algorithm that was used by the company, and it is the best-known. (See <http://en.wikipedia.org/wiki/PageRank> ⁶⁸ .)

Go back to Question 15 (p. 2095)

5.3.2.4.2 Answer 14

True. (See <http://en.wikipedia.org/wiki/PageRank> ⁶⁹ .)

Go back to Question 14 (p. 2095)

5.3.2.4.3 Answer 13

True. (See http://en.wikipedia.org/wiki/Search_engine_optimization ⁷⁰ .)

Go back to Question 13 (p. 2095)

⁶⁸<http://en.wikipedia.org/wiki/PageRank>

⁶⁹<http://en.wikipedia.org/wiki/PageRank>

⁷⁰http://en.wikipedia.org/wiki/Search_engine_optimization

5.3.2.4.4 Answer 12

False. The prototype for the Google search engine was developed by Sergey Brin and Lawrence Page at Stanford. (See *The Anatomy of a Large-Scale Hypertextual Web Search Engine*⁷¹ .) Apparently that prototype search engine was known as "Backrub".

Go back to Question 12 (p. 2094)

5.3.2.4.5 Answer 11

True. (See <http://moz.com/beginners-guide-to-seo/how-search-engines-operate>⁷² .)

Go back to Question 11 (p. 2094)

5.3.2.4.6 Answer 10

False. When a person performs an online search, the search engine scours its corpus of billions of documents, (which was created earlier by crawling and indexing web sites) and does two things: first, it returns only those results that are relevant or useful to the searcher's query; second, it ranks those results according to the popularity of the websites serving the information. It is both relevance and popularity that the process of Search Engine Optimization is meant to influence. (See <http://moz.com/beginners-guide-to-seo/how-search-engines-operate>⁷³ .)

Go back to Question 10 (p. 2094)

5.3.2.4.7 Answer 9

True. (See http://en.wikipedia.org/wiki/Search_engine_optimization⁷⁴ .)

Go back to Question 9 (p. 2094)

5.3.2.4.8 Answer 8

True. (See <http://moz.com/beginners-guide-to-seo/how-search-engines-operate>⁷⁵ .)

Go back to Question 8 (p. 2094)

5.3.2.4.9 Answer 7

True. (See <http://moz.com/beginners-guide-to-seo/how-search-engines-operate>⁷⁶ .)

Go back to Question 7 (p. 2094)

5.3.2.4.10 Answer 6

False. To cause a webpage to perform better in search engine listings, the most important content should be in HTML text format. Images, Flash files, Java applets, and other non-text content are often ignored or devalued by search engine crawlers. The easiest way to ensure that the words and phrases you display to your visitors are visible to search engines is to place them in the HTML text on the page. (See <http://moz.com/beginners-guide-to-seo/basics-of-search-engine-friendly-design-and-development>⁷⁷ .)

Go back to Question 6 (p. 2094)

⁷¹<http://infolab.stanford.edu/~backrub/google.html>

⁷⁴http://en.wikipedia.org/wiki/Search_engine_optimization

⁷⁵<http://moz.com/beginners-guide-to-seo/how-search-engines-operate>

⁷⁶<http://moz.com/beginners-guide-to-seo/how-search-engines-operate>

⁷⁷<http://moz.com/beginners-guide-to-seo/basics-of-search-engine-friendly-design-and-development>

5.3.2.4.11 Answer 5

False. Despite the use of the terms "allow" and "disallow", the **robots exclusion standard** is purely advisory. It relies on the cooperation of the web robot, so that marking an area of a site "out of bounds" with **robots.txt** does not guarantee exclusion of all web robots. (See http://en.wikipedia.org/wiki/Robots_exclusion_standard⁷⁸ .)

Go back to Question 5 (p. 2094)

5.3.2.4.12 Answer 4

True. (See http://en.wikipedia.org/wiki/Robots_exclusion_standard⁷⁹ .)

Go back to Question 4 (p. 2093)

5.3.2.4.13 Answer 3

False. Not all robots cooperate with the standard including email harvesters, spambots and malware robots that scan for security vulnerabilities. (See http://en.wikipedia.org/wiki/Robots_exclusion_standard⁸⁰ .)

Go back to Question 3 (p. 2093)

5.3.2.4.14 Answer 2

True. (See http://en.wikipedia.org/wiki/Robots_exclusion_standard⁸¹ .)

Go back to Question 2 (p. 2093)

5.3.2.4.15 Answer 1

False. The **robots exclusion standard** , also known as the **robots exclusion protocol** or **robots.txt protocol** , is a standard used by websites to communicate with web crawlers and other web robots. (See http://en.wikipedia.org/wiki/Robots_exclusion_standard⁸²)

Go back to Question 1 (p. 2093)

5.3.2.5 Miscellaneous

This section contains a variety of miscellaneous information.

5.4 Servlets

5.4.1 Java4530: Getting Started with Servlets⁸³

5.4.1.1 Table of Contents

- Preface (p. 2099)
 - Servlets, search engines, or JSON (p. 2099)
 - Getting started (p. 2100)
 - Viewing tip (p. 2100)
 - * Figures (p. 2100)
 - * Listings (p. 2100)
- General background information (p. 2100)
 - Test for a successful connection on localhost (p. 2100)
 - Upgrading your Java development environment (p. 2102)
- Discussion and sample code (p. 2102)
- What's next? (p. 2104)
- Miscellaneous (p. 2104)
- Complete program listings (p. 2106)

5.4.1.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX. The purpose of this module is to get you started writing, deploying, and testing Java servlets.

5.4.1.2.1 Servlets, search engines, or JSON

As explained in the page titled Java4510: Preface to INEW 2338⁸⁴, only one of the topics *Search Engines*, *Servlets*, or *JSON* is covered in the course in any particular semester. However, all three are important. The course material in the Blackboard course management program indicates which topic is covered in the current semester.

Students are encouraged to study all three topics for their own educational purposes in order to enhance their prospects of landing a job as a Java programmer.

⁸³This content is available online at <<http://cnx.org/content/m48509/1.7/>>.

⁸⁴<http://cnx.org/contents/yWyT-uhM:boF3E5Bs>

5.4.1.2.2 Getting started

If you haven't done so already, I strongly recommend that you study the following two modules before continuing with this module:

- Java4307: Servlets and JSP ⁸⁵
- Java4308: Deploying JSP and Servlets ⁸⁶

While studying Java4308 ⁸⁷, I recommend that you download, install on your local machine, and test the **Apache Tomcat** web server. Eventually students enrolled in this course will deploy and test their servlet programs on a web server operated by the college. However, the first several modules in this sub-collection will expect students to deploy and test servlets on a local web server.

5.4.1.2.3 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.4.1.2.3.1 Figures

- Figure 1 (p. 2100) . Web server test.
- Figure 2 (p. 2102) . Inew2338_050.java.
- Figure 3 (p. 2103) . Inew2338_051.java.
- Figure 4 (p. 2103) . Inew2338_052.jsp.

5.4.1.2.3.2 Listings

- Listing 1 (p. 2106) . Inew2338_050.java.
- Listing 2 (p. 2106) . Inew2338_051.java.
- Listing 3 (p. 2108) . Inew2338_052.jsp.

5.4.1.3 General background information

5.4.1.3.1 Test for a successful connection on localhost

Assuming that you have properly installed the Tomcat web server on your machine, you should be able to start the server and point your browser to **http://localhost:8080/** to see something similar to Figure 1 (p. 2100) in your browser.

Figure 1 - Web server test.

If you don't see that, you should probably rectify the problem before continuing.

While you are there, stop and examine the page showing in your browser window. It is packed with information regarding Tomcat, including documentation and the source code for numerous servlet and JSP examples.

5.4.1.3.2 Upgrading your Java development environment

In Java4308 ⁸⁸, I showed you how to upgrade your Java development environment to include two jar files named

- servlet.jar
- server.jar

I also explained that only the first one may actually be required, but since they are both small, there is no harm in having both of them on your machine.

I showed you how to create a batch file for compiling your servlet. The batch file that I provided includes these jar files on the classpath. This has the effect of making the following packages, among others, available to your compiler. This is a requirement for writing and compiling servlets and JSP.

- javax.servlet
- javax.servlet.http
- javax.servlet.jsp

You should make certain that you can successfully compile, deploy, and access the sample servlet that I provided in Java4308 ⁸⁹ before continuing with this module.

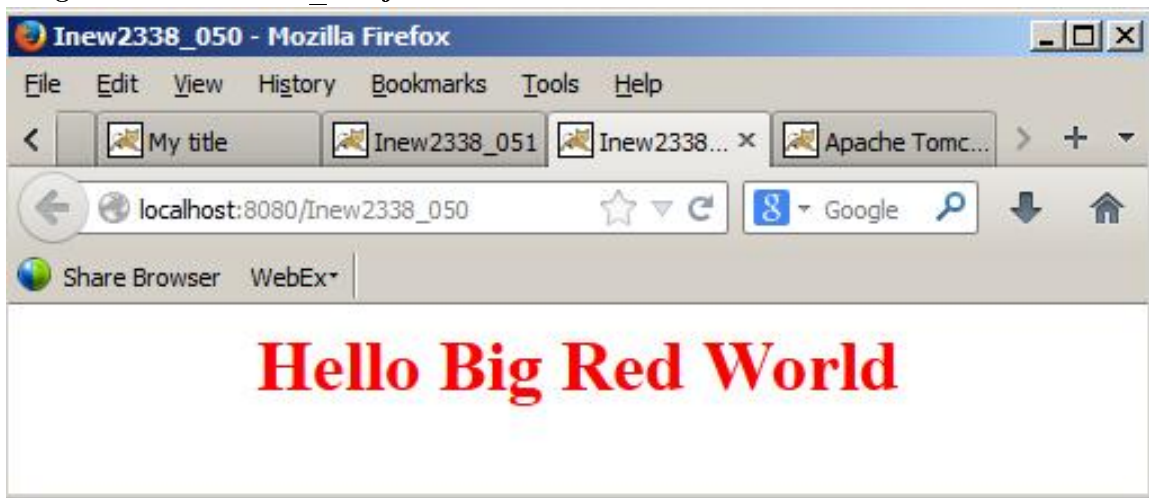

5.4.1.4 Discussion and sample code

Before leaving this module, let's make absolutely certain that everything is working by creating, compiling, deploying, and accessing two servlets and one JSP.

Using what you learned in Java4308 ⁹⁰, create compile and deploy the two servlets shown in Listing 1 (p. 2106) and Listing 2 (p. 2106). Then create and deploy the JSP shown in Listing 3 (p. 2108).

Start your server and point your browser to **http://localhost:8080/Inew2338_050** in order to see Figure 2 (p. 2102) in your browser.

Figure 2 - Inew2338_050.java.

⁸⁹http://cnx.org/content/m48488/latest/#Set_up_the_Java_Development_Kit

⁹⁰<http://cnx.org/content/m48488/latest/?collection=coll1441/latest>

Point your browser to http://localhost:8080/Inew2338_051 in order to see Figure 3 (p. 2103) in your browser.

Figure 3 - Inew2338_051.java.

Point your browser to http://localhost:8080/Inew2338_052.jsp in order to see Figure 4 (p. 2103) in your browser.

Figure 4 - Inew2338_052.jsp.

5.4.1.5 What's next?

If those tests were successful, your system is ready for you to move on to the next module and begin learning the programming details required to create Java servlets.

5.4.1.6 Miscellaneous

This section contains a variety of miscellaneous information.

5.4.2 Java4530r-Review⁹¹

5.4.2.1 Table of Contents

- Preface (p. 2109)
- Questions (p. 2109)
 - 1 (p. 2109) , 2 (p. 2109)
- Answers (p. 2111)
- Miscellaneous (p. 2111)

5.4.2.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX.

This module contains review questions and answers keyed to the module titled Java4530: Getting Started with Servlets⁹² in the Servlets sub-collection.

Once you study that module, you should be able to answer the review questions in this module.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

5.4.2.3 Questions

5.4.2.3.1 Question 1

True or False?

Assuming that you have properly installed the Tomcat web server on your local machine, you should be able to start the server and point your browser to **http://localhost:80/** to see the Tomcat startup screen in your browser.

Go to answer 1 (p. 2111)

5.4.2.3.2 Question 2

True or False?

Including the following packages on your classpath is a requirement for writing and compiling servlets and JSP.

- javax.servlet
- javax.servlet.http
- javax.servlet.jsp

Go to answer 2 (p. 2111)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

⁹¹This content is available online at <<http://cnx.org/content/m49581/1.2/>>.

⁹²<http://cnx.org/content/m48509/latest/?collection=col11441/latest>

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.4.2.4 Answers

5.4.2.4.1 Answer 2

True.

Go back to Question 2 (p. 2109)

5.4.2.4.2 Answer 1

False. Assuming that you have properly installed the Tomcat web server on your local machine, you should be able to start the server and point your browser to **http://localhost:8080/** to see the Tomcat startup screen in your browser. (*Note the port number.*)

Go back to Question 1 (p. 2109)

5.4.2.5 Miscellaneous

This section contains a variety of miscellaneous information.

5.4.3.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX.

5.4.3.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.4.3.2.1.1 Figures

- Figure 1 (p. 2113) . Output from Servlet01.java.

5.4.3.2.1.2 Listings

- Listing 1 (p. 2113) . Import directives.
- Listing 2 (p. 2114) . Beginning of the class definition.
- Listing 3 (p. 2114) . Beginning of the overridden doGet method.
- Listing 4 (p. 2115) . Preparing to return a response.
- Listing 5 (p. 2115) . Construct and return an HTML file.
- Listing 6 (p. 2121) . Servlet01.java.

5.4.3.3 General background information

Servlets are modules that run inside *request/response-oriented* servers, such as Java-enabled web servers, and extend them in some manner. For example, a servlet might be responsible for taking data in an HTML order-entry form and applying the business logic used to update a company's order database.

Servlets are to servers what applets are to browsers. The Servlet API, which you use to write servlets, assumes nothing about how a servlet is loaded, the server environment in which the servlet runs, or the protocol used to transmit data to and from the user. This allows servlets to be embedded in many different web servers.

Servlets are an effective substitute for CGI scripts. They provide a way to generate dynamic documents that is both easier to write and faster to run. They also address the problem of doing server-side programming with platform-specific APIs.

In some ways, a servlet is similar to an applet. An applet is a chunk of Java code that executes under control of a browser. A servlet is a chunk of Java code that executes under control of a server program.

You must run your servlet under the control of a Java-enabled server program. The first few modules in this sub-collection will use the Apache Tomcat ⁹⁴ server for that purpose.

Please note that the use of servlets is not restricted to HTTP servers. However, the discussion in this lesson and most of the follow-on modules will generally apply only to HTTP servers.

⁹⁴<http://cnx.org/content/m48488/latest/?collection=col11441/latest>

5.4.3.4 Discussion and sample code

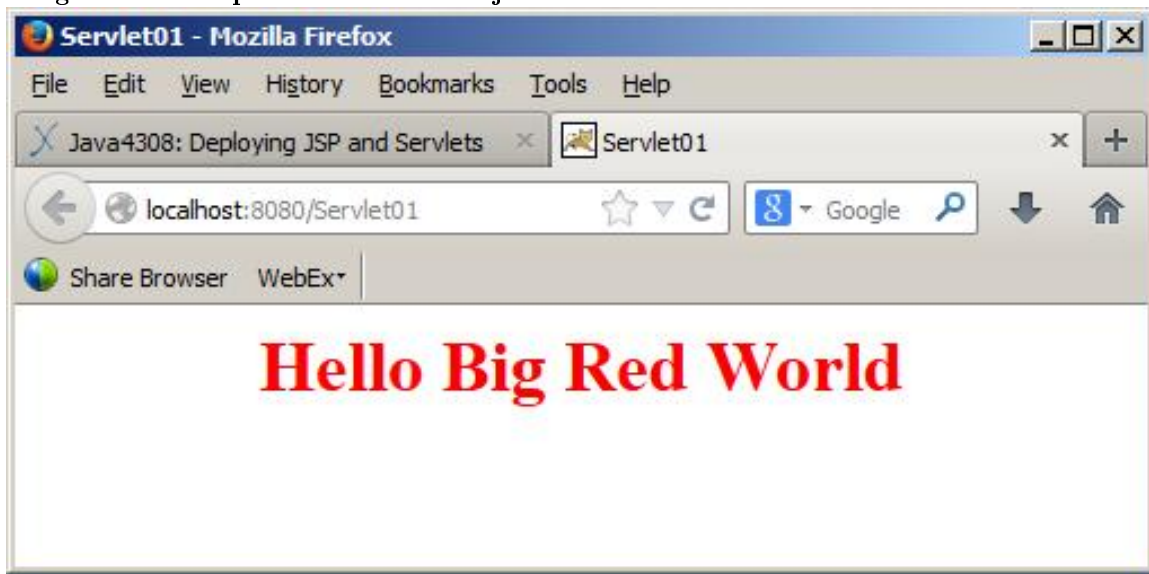

5.4.3.4.1 The program named Servlet01.java

In this module, I will discuss servlets using a sample servlet program named **Servlet01.java** as a guide. A complete listing of the program is shown in Listing 6 (p. 2121) .

This program will illustrate some, but not all of material that I will discuss in this module. The purpose of this program is to illustrate a very simple servlet and to serve as a vehicle for discussion of various aspects of servlets.

The servlet produces the screen output in the browser shown in Figure 1 (p. 2113) .

Figure 1 - Output from Servlet01.java.

5.4.3.4.2 Interesting code fragments

Import directives

I will explain the program code in fragments. The first fragment in Listing 1 (p. 2113) shows the import directives necessary to support servlet programming.

Listing 1 - Import directives.

```
import java.io.*;
import javax.servlet.*;
import javax.servlet.http.*;
```

Table 5.61

The Servlet interface

All servlets must implement the **Servlet** interface. You can implement it directly. However, it is more common to implement it indirectly by extending a class that implements the interface (such as **HttpServlet**).

The **Servlet** interface declares methods for managing the servlet and its communications with clients. You will need to override some or all of those methods when you write your servlet.

Listing 2 (p. 2114) shows the beginning of the controlling class for the servlet. Note that the servlet class extends `HttpServlet`. By extending the `HttpServlet` class, the servlet implements the `Servlet` interface indirectly.

Listing 2 - Beginning of the class definition.

```
public class Servlet01 extends HttpServlet{
```

Table 5.62

Request and response objects

Two object references are passed to a servlet when it called by a client:

- **ServletRequest** - encapsulates the communication from the client to the server.
- **ServletResponse** - encapsulates the communication from the servlet back to the client

Access to these objects can be accomplished in more than one way. This servlet overrides the `doGet` method, which receives references to the two objects as incoming parameters.

The overridden doGet method

The beginning of the overridden `doGet` method is shown in Listing 3 (p. 2114).

Listing 3 - Beginning of the overridden doGet method.

```
public void doGet(HttpServletRequest req,
                  HttpServletResponse res)
    throws ServletException, IOException{
```

Table 5.63

Note that the `doGet` method throws an exception of type `ServletException`. In this servlet, some of the code inside the `doGet` method also throws an `IOException`, which is not handled inside the method. Thus, it is declared in the method signature.

Browser commands and servlet methods

A Java-enabled server provide a method corresponding to each of the commands that an HTTP client can send to its server. When the server receives a command from the client, the corresponding method is called on the servlet.

As the servlet programmer, you override some or all of those methods to provide the desired behavior.

The doGet method and the HTTP GET command

The `doGet` method corresponds to the HTTP `GET` command. If you don't override the method, the default implementation reports an `HTTP BAD_REQUEST` error when the browser sends a `GET` command.

Overriding the `doGet` method to support the `GET` command also automatically supports the HTTP `HEAD` command.

(The `HEAD` command is a `GET` command that returns no body in the response. It just returns the requested header fields.)

The fundamental purpose of the `GET` command makes it possible for the client to *get something* from the server. When you override the `doGet` method, you should

- Read data from the request
- Construct the proper headers in the response
- Gain access to either the writer or the output stream (*depending on whether the material to be returned is text or binary data*)
- Write the response data

Responding to the request

The headers should include content type and encoding. The content type must be set before the writer is accessed.

This servlet constructs and returns a simple HTML file containing formatted text. Listing 4 (p. 2115) shows the use of `setContentType` method of the response object to set the content type being returned before accessing the writer. Then the `getWriter` method of the response object is used to get access to the output stream.

Listing 4 - Preparing to return a response.

```
res.setContentType("text/html");
PrintWriter out = res.getWriter()
```

Table 5.64

You will need to do some research on your own to learn about the different content types that can be returned by a servlet.

The `PrintWriter` object referred to by `out` is used to construct output text in Listing 5 (p. 2115) .

Construct and return an HTML file

That brings us to the fragment in Listing 5 (p. 2115) , which constructs and returns the various elements of an HTML page and then terminates the `doGet` method.

Listing 5 - Construct and return an HTML file.

```
out.println("<html>");
out.println("<head><title>Servlet01</title></head>");
out.println("<body>");

out.println("<h1 align=\"center\">"
           +"<font color=\"#FF0000\">");
out.println("Hello Big Red World");
out.println("</font></h1>");

out.println("</body></html>");
} //end doGet()
} //end class Servlet01
```

Table 5.65

Constructing the HTML code

The code in Listing 5 (p. 2115) constructs a series of **String** objects and passes them as parameters to the **println** method of the **PrintWriter** object referred to by **out**. The content of the **String** objects is raw HTML code.

A tedious process: Constructing raw HTML code as a series of Java String objects can be a very tedious and error-prone process, due particularly to the frequent need to use the backslash escape character for quotation marks inside the strings. (*All attribute values in HTML must be surrounded by quotation marks.*)

This is one of the arguments for the use of JSP that you learned about in the prerequisite course⁹⁵. One of the benefits of JSP is that it can greatly reduce the amount of raw HTML code that you must construct to send back a typical HTML web page.

If you have written any raw HTML code, you will probably recognize the construction of the HTML code in Listing 5 (p. 2115) (*and you may also recognize the HTML code as being vintage 1999 when the servlet program was written*).

If you haven't written any HTML, you will need to do a little research on your own to learn about the various parts of an HTML page. At this level, it is fairly simple.

(An HTML element often consists of text content surrounded by opening and closing tags of a particular type. Elements can also be nested inside of other elements creating a hierarchical tree of elements.)

The content between the opening and closing **body** tags in Listing 5 (p. 2115) represents the real information content of the page. The rest is mostly formatting information.

This body content in Listing 5 (p. 2115) says to

- Set the text to style h1 (*which is a maximum size header*).
- Center it on the page.
- Set the color to hexadecimal FF0000, which is the color value for pure red (*in a red, green, blue color system*).

Most (*but not all*) HTML elements, such as the **body** element, require an opening tag and a closing tag. Thus, most tag types come in pairs.

An HTML page is pure text with the various elements specifying how the browser is to interpret and display that text. (*The text can also refer to other files such as image files and cause the content of those files to be included in the rendered output produced by the browser.*)

The Java code in this servlet simply prints the requisite HTML text to the output stream referred to by **out**. Recall from Listing 4 (p. 2115) that the reference to the output stream was obtained by calling the **getWriter** method on the **HttpServletResponse** object. That object takes care of transporting the text back to the client browser.

5.4.3.4.3 But wait, there's more

Usually in most modules, when I complete the discussion of the last sample program, that is the end of the module. In this module, however, there are several other important topics that I want to discuss before ending the module.

The ServletRequest object

One of the incoming objects to the servlet is of type **ServletRequest**. This is not the name of a class. Instead, this is a type defined by an interface of the same name. This interface declares more than 30 methods by which the servlet can extract incoming information from the object. This framework provides the servlet's only access to incoming data.

⁹⁵<http://cnx.org/content/m48057/latest/?collection=col11441/latest>

The data provided by the `ServletRequest` object includes parameter names and values, attributes, and an input stream.

Interfaces that extend `ServletRequest` can provide additional protocol-specific data. For example, HTTP data is provided by the interface `HttpServletRequest`, which extends `ServletRequest`. (Recall from Listing 3 (p. 2114) that the `doGet` method receives a reference to an `HttpServletRequest` object as an incoming parameter.)

Suffice it to say that it is possible for the servlet to obtain a great deal of information in order to carry out its duties. (I will refer you to the online documentation⁹⁶ for more information about the available methods.)

The `ServletResponse` object

The other incoming object to the servlet is an object of type `ServletResponse`. This is also a type defined by an interface of the same name. This interface declares more than 15 methods by which the servlet can return data to the client.

The content type

Recall that Listing 4 (p. 2115) calls the `setContentTypes` method on the response object to set the type of the data being returned by this servlet to "text/html". It is also possible to set the character encoding in a call to `setContentTypes` with something like

```
text/html;charset=UTF-8
```

The rules for doing that are fairly complicated, so you would do well to consult the Java documentation for the `setContentTypes` method before trying to deal with that possibility.

Persistence

We have discussed the classes and interfaces that make up a basic Servlet. HTTP servlets have additional objects that provide session-tracking capabilities. The servlet writer can use these APIs to maintain state between the servlet and the client that persists across multiple connections during some time period.

The servlet life cycle

Servlets have a prescribed life cycle. Servers load and run servlets. Servers accept requests from clients, and may use their servlets to return data to the clients.

Servers can also remove servlets. So, the stages of a servlet's life cycle are:

- The servlet is loaded and initialized.
- The servlet is used to satisfy client requests.
- The servlet is removed or unloaded.

A server runs the servlet's `init` method when it loads the servlet. Most servlets are run in multi-threaded servers. However, there are no concurrency issues during servlet initialization. The server calls the `init` method when it loads the servlet, and does not call it again unless it is reloading the servlet.

The server cannot reload a servlet until after it has removed the servlet by calling the `destroy` method. Initialization is allowed to complete before client requests are handled or the servlet is destroyed.

A practical problem

This can be a problem when you are developing a servlet and repeatedly testing it with a server. Once the servlet is initially loaded from the class file, for some servers simply providing a new class file does not cause the server to remove the old version of the servlet and load the new version. (This appears to be the case with the Apache Tomcat⁹⁷ server that we will be using for some of these modules.)

With the Apache Tomcat⁹⁸ server, you must stop and restart the server to cause it to load the new version of a servlet. (It may be possible to use some feature of the administration tool to force the server to remove an old version and load a new version of a servlet without stopping and restarting the server but I have never investigated that possibility.)

The second stage

⁹⁶<http://docs.oracle.com/javaee/7/api/>

⁹⁷<http://cnx.org/content/m48509/latest/?collection=col11441/latest>

⁹⁸<http://cnx.org/content/m48488/latest/?collection=col11441/latest>

The second stage in the life of the servlet begins after the servlet has been loaded and initialized. At that point, the server may call upon the servlet to respond to client requests. In so doing, the servlet handles client requests by processing them in its `service` method, which is called by the server. Normally, the service request from each client is run in a separate thread by the servlet.

Generic versus HTTP servlets

If you are writing a generic servlet, you will probably override the `service` method. However, if you are writing servlets to be used with HTTP servers, you probably won't need to override `service`. The `service` method of the `HttpServlet` class handles the setup and dispatches the request to methods such as `doGet` and `doPost`. When writing HTTP servlets, you will normally extend the `HttpServlet` class and override the `doXXX` methods instead of overriding the `service` method.

Multithreaded operation

Servlets can process requests from multiple clients concurrently in a multithreaded manner. This means that the service methods should be written to be thread safe. One description that I have seen for how to write a thread-safe method is to:

Use the fewest possible number of instance variables, and synchronize access to them if you use them.

Single-threaded operation

In some cases and for some reason known only to you, you may decide to prevent your servlet from processing concurrent client requests. In this case, you should cause your servlet to implement the `SingleThreadModel` interface. This interface guarantees that no two threads will execute the servlet's service methods concurrently. Implementing the interface does not require writing any extra methods. Merely declaring that the servlet implements the interface is sufficient to prevent the server from making concurrent calls to the service method.

(This may not make you popular with the server administrator because it could cause your single-threaded servlet to become a bottleneck.)

The third stage

The third and last stage of a servlet's life cycle is removal. When a server removes a servlet, it runs the servlet's `destroy` method. This method is run only once. The server will not run it again until after it reloads and reinitializes the servlet. When the `destroy` method runs, other threads might be running service requests. If it is necessary to access shared resources while doing cleanup, that access should be synchronized.

The javax.servlet.Servlet interface

Servlets must implement the `javax.servlet.Servlet` interface. For writing servlets that run under control of servers that use the HTTP protocol, the most common way to write servlets is to extend the `javax.servlet.http.HttpServlet` class which is a way to indirectly implement the `Servlet` interface.

The `HttpServlet` class implements the `Servlet` interface by extending the `GenericServlet` base class, and provides a framework for handling the HTTP protocol.

Four methods

For servlets that extend the `HttpServlet` class, the following four methods may be overridden to cause your servlet to interact with the client.

- `doGet` - for handling GET, conditional GET and HEAD requests
- `doPost` - for handling POST requests
- `doPut` - for handling PUT requests
- `doDelete` - for handling DELETE requests

You may need to do some outside research on the HTTP protocol to learn about the nature of each type of client request listed above. You may also want to go back and review Java4350: Form Processing with JSP⁹⁹ for information regarding the differences between the HTML GET and POST methods.

⁹⁹<http://cnx.org/content/m48085/latest/?collection=col11441/latest>

By default, if called but not overridden, these methods return a `BAD_REQUEST` (400) error.

The servlet discussed earlier used the `doGet` method to handle `GET` requests.

Differences between `doGet` and `doPost`

I will describe a couple of differences between the two methods that you may find useful. Assume there is a servlet named `Java4550a` on a localhost web server. You can execute that servlet by typing the following address into the address field of the browser and pressing the **Enter key** :

```
http://localhost:8080/Java4550a
```

First consider the contents of the browser's address window. When an HTML page calls the `doGet` method of a servlet named `Java4550a` , you will often see something like the following in the address window:

```
http://localhost:8080/Java4550a?firstName=Dick...
```

As you can see, some information has been appended onto the end of the address with the `?` character being used to separate the two.

However, if the HTML page calls the `doPost` method of the same servlet, this is what you should see:

```
http://localhost:8080/Java4550a
```

(Note that some browsers don't display the `http://` portion of the address.)

In other words, with the `doPost` method, no visible information is appended onto the actual address as is the case with the `doGet` method.

It is probably also safe to say that the `doGet` method is the default. By this, I mean that if you enter address given above (p. 2119) into the browser's address field and press the Enter key, the `doGet` method (and not the `doPost` method) belonging to the servlet named `Java4550a` will be called.

(The same is true if you put this address into a simple hyperlink when creating a web page.)

If you want to manually enter an address into the address field and cause the `doPost` method to be called, you must find some other way to do it.

Arguments

Each of the methods requires two arguments. The first, a reference to an `HttpServletRequest` object, encapsulates the data from the client. The second, a reference to an `HttpServletResponse` object encapsulates the response to the client.

The `HttpServletRequest` object provides a large number of methods that the servlet can use to obtain information about the request.

Similarly, the `HttpServletResponse` object provides a large number of methods that the servlet can use to return data to the client.

The `init` and `destroy` methods

You may also find that you need to override the `init` and `destroy` methods in your servlet. Recall that each of these methods is called only once. The `init` method is called when the server loads the servlet class. The `destroy` method is called when the server removes the servlet class.

Overriding the `init` method

The servlet should use the `init` method to prepare the resources it manages and to make the servlet ready to handle client requests. It can do this without regard for multi-threading issues because it is guaranteed that there is only a single thread running during initialization. If the `init` method is unable to run to a successful completion, it should throw an `UnavailableException` object.

The `init` method receives a `ServletConfig` object as a parameter. For reasons that I won't bother to discuss here, the overridden `init` method should call `super.init` and pass this configuration object as a parameter. If you are curious as to the reasons, you can look it up in the documentation.

Overriding the `destroy` method

Overriding the `destroy` method is more problematic, particularly if it is necessary to deal with resources that may be shared by service threads that are still running when the server decides to remove the servlet and call its `destroy` method. I'm going to punt on this one, and suggest that if you find yourself in this

situation, you should find a good book with an example similar to your situation and use that example for guidance.

The `getServletInfo` method

Some applications may want to display information about a servlet, such as a short description of the purpose of the servlet, its author, and perhaps its version number. The **Servlet** API provides a method named `getServletInfo` to return this kind of information about the servlet. By default, this method returns null. You can override this method to return a **String** containing information about your servlet.

5.4.3.5 What's next?

The next module in the series will take on forms and databases.

5.4.3.6 Miscellaneous

This section contains a variety of miscellaneous information.

5.4.3.7 Complete program listing

Listing 6 - Servlet01.java.

```

/*File Servlet01.java, Copyright 1999, R.G.Baldwin

The purpose of this program is to illustrate a very
simple servlet.

The servlet produces the following text in the browser
window in large red letters.

Hello Big Red World
*****/
import java.io.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class Servlet01 extends HttpServlet{
    public void doGet(HttpServletRequest req,
                      HttpServletResponse res)
                      throws ServletException, IOException{

        //Establish the type of output
        res.setContentType("text/html");

        //Get an output stream
        PrintWriter out = res.getWriter();

        //Construct an html page to return to the client
        out.println("<html>");
        out.println("<head><title>Servlet01</title></head>");
        out.println("<body>");

        out.println("<h1 align=\"center\">"
                    +"<font color=\"#FF0000\">");
        out.println("Hello Big Red World");
        out.println("</font></h1>");

        out.println("</body></html>");
    } //end doGet()
} //end class Servlet01

```

- Miscellaneous (p. 2128)

5.4.4.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX.

This module contains review questions and answers keyed to the module titled Java4535: Introduction to Servlet Code¹⁰¹ in the Servlets sub-collection.

Once you study that module, you should be able to answer the review questions in this module.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

5.4.4.3 Questions

5.4.4.3.1 Question 1

True or False?

Servlets are programming modules that run inside *request/response-oriented* servers, such as Java-enabled web servers, and extend them in some manner.

Go to answer 1 (p. 2128)

5.4.4.3.2 Question 2

True or False?

You can run servlet programs on any server that supports the HTTP protocol.

Go to answer 2 (p. 2128)

5.4.4.3.3 Question 3

True or False?

The use of servlets is restricted to HTTP servers.

Go to answer 3 (p. 2128)

5.4.4.3.4 Question 4

True or False?

The following import directives, as a minimum, are necessary to support servlet programming:

- `import java.io.*;`
- `import javax.servlet.*;`
- `import javax.servlet.http.*;`

Go to answer 4 (p. 2128)

¹⁰⁰This content is available online at <http://cnx.org/content/m49594/1.2/>.

¹⁰¹<http://cnx.org/content/m48518/latest/?collection=col11441/latest>

5.4.4.3.5 Question 5

True or False?

All servlets must implement the **JavaServlet** interface. You can implement it directly. However, it is more common to implement it indirectly by extending a class that implements the interface (*such as **HttpJavaServlet***).

Go to answer 5 (p. 2128)

5.4.4.3.6 Question 6

True or False?

The **Servlet** interface declares methods for managing the servlet and its communications with clients. You will need to override some or all of those methods when you write your servlet.

Go to answer 6 (p. 2127)

5.4.4.3.7 Question 7

True or False?

Object references of the following types are passed to a servlet when it called by a client:

- **JavaServletRequest** - encapsulates the communication from the client to the server.
- **JavaServletResponse** - encapsulates the communication from the servlet back to the client

Go to answer 7 (p. 2127)

5.4.4.3.8 Question 8

True or False?

For an HTTP servlet, the **doGet** method receives references to two objects of the following types as incoming parameters:

- **HttpServletRequest**
- **HttpServletResponse**

Go to answer 8 (p. 2127)

5.4.4.3.9 Question 9

True or False?

A Java-enabled server provide a method to support each of the commands that an HTTP client can send to its server. When the server receives a command from the client, the corresponding method is called on the servlet.

As the servlet programmer, you override some or all of those methods to provide the desired behavior.

Go to answer 9 (p. 2127)

5.4.4.3.10 Question 10

True or False?

The **doGet** method corresponds to the HTTP **POST** command. If you don't override the method, the default implementation reports an **HTTP BAD_REQUEST** error when the browser sends a **POST** command.

Go to answer 10 (p. 2127)

5.4.4.3.11 Question 11

True or False?

Overriding the `doGet` method to support the `GET` command also automatically supports the HTTP `HEAD` command.

Go to answer 11 (p. 2127)

5.4.4.3.12 Question 12

True or False?

The fundamental purpose of the `GET` command makes it possible for the client to *get something* from the server. When you override the `doGet` method, you should, as a minimum:

- Read data from the request
- Construct the proper headers in the response
- Gain access to either the writer or the output stream (*depending on whether the material to be returned is text or binary data*)
- Write the response data

Go to answer 12 (p. 2127)

5.4.4.3.13 Question 13

True or False?

The headers that you create in your overridden `doGet` method should include content type and encoding. The content type must be set before the writer is accessed. The `setContent-type` method of the response object can be called to set the content type. The `getWriter` method of the response object can be called to get access to the output stream.

Go to answer 13 (p. 2127)

5.4.4.3.14 Question 14

True or False?

The class definition for an HTTP servlet extends the `JavaHttpServlet` class.

Go to answer 14 (p. 2127)

5.4.4.3.15 Question 15

True or False?

Servlets typically process requests from multiple clients concurrently in a multithreaded manner. However, it is possible to write servlets that are restricted to single-threaded operation by implementing the `SingleThreadModel` interface.

Go to answer 15 (p. 2126)

5.4.4.3.16 Question 16

True or False?

When writing a servlet for multi-threaded operation, you should use the fewest possible number of instance variables, and synchronize access to them if you use them.

Go to answer 16 (p. 2126)

5.4.4.3.17 Question 17

True or False?

For servlets that extend the **HttpServlet** class, the following methods may be overridden to cause your servlet to interact with the client.

- **doGet** - for handling GET, conditional GET and HEAD requests
- **doPost** - for handling POST requests
- **doPut** - for handling PUT requests
- **doDelete** - for handling DELETE requests
- **doTerminate** - for terminating the servlet and returning control to the browser

Go to answer 17 (p. 2126)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.4.4.4 Answers

5.4.4.4.1 Answer 17

False.

For servlets that extend the **HttpServlet** class, the following four methods may be overridden to cause your servlet to interact with the client.

- **doGet** - for handling GET, conditional GET and HEAD requests
- **doPost** - for handling POST requests
- **doPut** - for handling PUT requests
- **doDelete** - for handling DELETE requests

Go back to Question 17 (p. 2125)

5.4.4.4.2 Answer 16

True.

Go back to Question 16 (p. 2124)

5.4.4.4.3 Answer 15

True.

Go back to Question 15 (p. 2124)

5.4.4.4.4 Answer 14

False. The class definition for an HTTP servlet extends the **HttpServlet** class.

Go back to Question 14 (p. 2124)

5.4.4.4.5 Answer 13

True.

Go back to Question 13 (p. 2124)

5.4.4.4.6 Answer 12

True.

Go back to Question 12 (p. 2124)

5.4.4.4.7 Answer 11

True.

Go back to Question 11 (p. 2124)

5.4.4.4.8 Answer 10

False. The **doGet** method corresponds to the HTTP **GET** command. If you don't override the method, the default implementation reports an **HTTP_BAD_REQUEST** error when the browser sends a **GET** command.

Go back to Question 10 (p. 2123)

5.4.5.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX. The purpose of this module is to explain session tracking using hidden fields, and to compare a servlet with a JSP to accomplish the same objective.

5.4.5.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.4.5.2.1.1 Figures

- Figure 1 (p. 2131) . The servlet user interface at startup.
- Figure 2 (p. 2132) . Browser display for Tom, Dick, and Harry.
- Figure 3 (p. 2133) . Hidden fields in the servlet output.

5.4.5.2.1.2 Listings

- Listing 1 (p. 2134) . Beginning of the servlet class.
- Listing 2 (p. 2135) . Get and save the hidden values from the browser page.
- Listing 3 (p. 2135) . Get and save user input data.
- Listing 4 (p. 2137) . Begin constructing the HTML output data.
- Listing 5 (p. 2137) . Begin the HTML code for an HTML form.
- Listing 6 (p. 2138) . An input field and a submit button.
- Listing 7 (p. 2138) . Beginning of the list of names.
- Listing 8 (p. 2139) . Display the historical data and also save it on the browser.
- Listing 9 (p. 2139) . Display most recent value and also store it on the browser.

¹⁰²This content is available online at <<http://cnx.org/content/m48550/1.5/>>.

- Listing 10 (p. 2140) . Create basic web page structure.
- Listing 11 (p. 2141) . A JSP scriptlet.
- Listing 12 (p. 2141) . The body of the for loop.
- Listing 13 (p. 2142) . Another scriptlet.
- Listing 14 (p. 2142) . Another JSP expression tag.
- Listing 15 (p. 2142) . Terminating scriptlet and HTML code.
- Listing 16 (p. 2143) . The servlet program named Java4550a.java.
- Listing 17 (p. 2146) . The JSP program named Java4550a.jsp.

5.4.5.3 General background information

A stateless protocol

The HTTP protocol is a relatively simple request/response protocol that does not retain historical information from one client request to the next. In other words, each request is a new start insofar as the HTTP server is concerned. (*HTTP is sometimes referred to as a "stateless" protocol.*) However, historical information can be very important. The maintenance of historical information is often referred to as "*session tracking.*"

Session tracking

Session tracking is very important for many web applications including web commerce and web games. Therefore, this and the next several modules will show you some of the ways that you can accomplish session tracking using servlets and JSP.

Web commerce

Perhaps the most common example of the need for session tracking is with a web commerce application involving a shopping cart. The customer (*client*) downloads various pages from a vendor catalog, selecting items, and placing them in a shopping cart. At some point, the customer decides either to purchase the items or abandon the shopping trip.

If the customer decides to purchase the items in the cart, the web application must have a record of all the items in the cart. Furthermore, that record must be associated with that particular customer so that the sale can be consummated.

Insofar as the HTTP protocol is concerned, each time the customer views a different page in the catalog, all information regarding previously viewed pages is forgotten. The HTTP protocol doesn't save state information regarding an ongoing session by that customer involving multiple pages. It is the responsibility of the application to track the session involving that client (*customer*) .

In the case of the shopping cart application, it is also the responsibility of the application to keep track of the items in the cart associated with that customer.

Session tracking using hidden fields

There are several different ways to accomplish session tracking with a servlet. This module will illustrate one of those ways, which is commonly known as *hidden fields* . Other ways will be illustrated in future modules

Some session tracking schemes maintain historical information over many user sessions on a website. Others schemes are more limited. The scheme that I will explain in this module is generally limited to one session consisting of multiple requests.

This scheme is probably not useful for large scale web commerce. However, it might be useful for an online game where the user makes a move and then clicks a **submit** button. The computer needs to remember the entire history of the game, but needn't necessarily remember the history if the user leaves the website by closing the browser page.

A servlet and a JSP

I will explain two different programs that accomplish the same purpose. One of the programs is a servlet. The other program is a JSP. You will see that the JSP version is physically easier to write than the servlet version. However, you probably need to understand the servlet version in order to understand the JSP

version. The two also differ in that the servlet is capable of determining the name of the server on which it is running but the JSP does not have that capability.

5.4.5.4 Discussion and sample code

I will discuss both programs in fragments. A complete listing of the servlet program named **Java4550a.java** is provided in Listing 16 (p. 2143) . A complete listing of the JSP program named **Java4550a.jsp** is provided in Listing 17 (p. 2146) .

5.4.5.4.1 The servlet program

The program output

Each time the servlet is called by a browser, it creates and displays an HTML form on the browser screen similar to that shown in Figure 1 (p. 2131) .

Figure 1 - The servlet user interface at startup.

The HTML form displays:

- An input text field through which the client can submit a name
- A submit button
- A list of previously submitted names

A new request

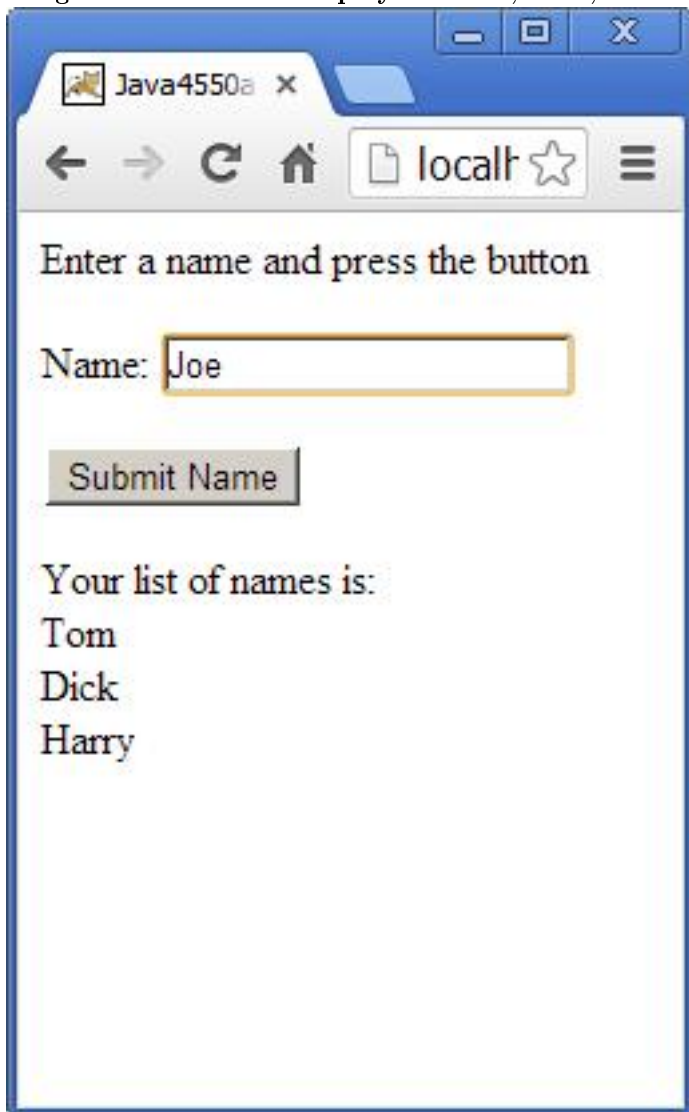

Each time the user clicks the **submit** button, the contents of the **Name** field are sent to the server and the server views that as a new request. The server does not remember historical information from one request to the next.

However, this servlet provides a mechanism by which a historical list of **Name** values from a sequence of requests is saved and displayed in the area identified as **Empty** in Figure 1 (p. 2131) .

Tom, Dick, and Harry

For example, Figure 2 (p. 2132) shows the browser display after the names Tom, Dick, and Harry have been sent to the server in three separate requests. (*Note the list of names near the left-center of Figure 2 (p. 2132) .*) The name Joe has been entered into the text field in Figure 2 (p. 2132) but the user has not clicked the submit button to send it to the server. Therefore, that name does not appear on the list.

Figure 2 - Browser display for Tom, Dick, and Harry.

The GET method

In this servlet, requests are sent from the browser to the server using the GET method. (*The POST method could also have been used.*) Each time the browser makes a GET request of the server, an HTML form is created by the servlet and sent back to the browser.

Hidden fields

Hidden fields are added to the form each time it is created by the servlet. One hidden field contains the name submitted for that GET request. Other hidden fields contain each of the names submitted by each previous GET request during the current session. In other words, the hidden fields on each successive form match those of the previous form plus a new hidden field for the new name submitted with that GET request.

Raw HTML code

Figure 3 (p. 2133) shows the HTML code returned to the browser following the sending of Tom, Dick, and Harry to the server in three separate requests. The three hidden fields are shown at the bottom.

Figure 3 - Hidden fields in the servlet output.

```

1 <html>
2 <head><title>Java4550a</title></head>
3 <body>
4 <form method='get' action='http://dell8700:8080/Java4550a'>
5 <p>Enter a name and press the button</p>
6 <p>Name: <input type='text' name='firstName'></p>
7 <input type='submit' value='Submit Name'>
8 <p>Your list of names is:<br/>
9 Tom<br/>
10 <input type='hidden' name='item' value='Tom'>
11 Dick<br/>
12 <input type='hidden' name='item' value='Dick'>
13 Harry<br/>
14 <input type='hidden' name='item' value='Harry'>
15 </form></body></html>
16

```

The term **dell8700** on the fourth line of Figure 3 (p. 2133) is the name of the computer on which the server that serviced the request was running.

If the user enters another name into the text field and clicks the submit button

- The new name will be sent to the servlet.
- This historical data will also be sent to the servlet.
- The new name will be appended onto the list.
- The new list will be sent back to the browser.

Save historical data in an HTML form

With this approach, the historical data is saved by embedding it in the new HTML form that is returned to the browser. There is no requirement to save the historical data in a database or in the server's file system. Note however, that the data will be lost if the user shuts down the browser or shuts down the computer. However, because of the browser cache, it is sometimes possible for the user to navigate to other web sites and then return to the same web page using the Back button and find that the historical data is still there.

Simple, reliable, and easy to implement

This approach has been used by web programmers for many years in those cases where it will get the job done. The approach is reliable and easy to implement. It places no special requirements on the server software (*other than the ability to support Java servlets*) and it is compatible with all browsers that support HTML forms.

5.4.5.4.1.1 Interesting code fragments

The doGet method

The code in Listing 1 (p. 2134) shows the beginning of the controlling class and the beginning of the `doGet` method for the servlet.

Listing 1 - Beginning of the servlet class.

```
import java.io.*;
import javax.servlet.*;
import javax.servlet.http.*;
import java.net.*;

public class Java4550a extends HttpServlet{
    public void doGet(HttpServletRequest req,
                      HttpServletResponse res)
                      throws ServletException, IOException{

        //Get and display name of localhost
        InetAddress inetAddress = InetAddress.getLocalHost();
        String hostName = inetAddress.getHostName();
        System.out.println(hostName);
    }
}
```

Table 5.67

The name of the server

Without getting into the details as to why, I will tell you that the last three lines of code in Listing 1 (p. 2134), (*in conjunction with the import directive for `java.net.*`*) cause the name of the computer on which the server is running to be saved in the variable named `hostName` and to be displayed on the Tomcat server console. You should have learned enough about the class named `InetAddress` earlier in this course to understand what is going on here without further explanation.

This is very important information for students enrolled in this course because this or something like it will be required for many of the programming assignments.

Two incoming parameters

Recall from previous modules that the `doGet` method receives two parameters. One parameter named `req` is a reference to an object of the interface type `HttpServletRequest` that contains all of the information sent by the browser when the request was made. The other parameter named `res` is a reference to an object of the interface type `HttpServletResponse` that collects output information and sends it back to the browser.

Both of those objects contain numerous methods that can be used to access incoming information (`req`) or to send information back to the browser (`res`). We will see several of those methods being used shortly.

A bit of technical trivia: `HttpServletRequest` and `HttpServletResponse` are interfaces, not classes. In general, we don't know the names of the classes from which the objects referred to by the incoming parameters were instantiated. And, we don't really care because we only plan to call methods on those objects that are declared in the interfaces that the objects implement.

However, just as a matter of technical trivia, it appears that those classes have the following names on my system:

```
org.apache.catalina.connector.RequestFacade
org.apache.catalina.connector.ResponseFacade
```

Multiple fields with the same name

An HTML form can have multiple fields with the same name. As you saw in Figure 3 (p. 2133), the hidden fields are all named `item`. The code in Listing 2 (p. 2135) calls the `getParameterValues` method on the request object to get the values stored in all of the hidden fields named `item`.

Listing 2 - Get and save the hidden values from the browser page.

```
String[] items = req.getParameterValues("item");
```

Table 5.68

The `getParameterValues` method receives the field name `item` as a `String` parameter and returns an array of `String` objects, containing all of the values with matching names contained in the request object, or null if the field name does not exist.

Those values are saved in the `String` array named `items` shown in Listing 2 (p. 2135). As you will see later, this is data that was saved from previous requests.

Get and save user input data

Listing 3 (p. 2135) calls the `getParameter` method on the request object to get and save the value submitted by the browser in the field named `firstName`. (See the *input* element on the sixth line in Figure 3 (p. 2133).) This is also the text field shown in Figure 2 (p. 2132).

Listing 3 - Get and save user input data.

```
String name = req.getParameter("firstName");
```

Table 5.69

The `getParameter` method receives the *name* of a request parameter and returns the *value* corresponding to that request parameter as a `String`, or null if the parameter does not exist. (Recall that the data is transmitted to the server as *name::value* pairs.)

Begin constructing the HTML output data

At this point in the process, all of the incoming data has been saved in a variable named `name` and an array named `items`. The time has come to construct the raw HTML code and send it back to the client. Listing 4 (p. 2137) begins that process by

- Telling the browser how to interpret the data ("text/html").
- Getting on output stream on the response object on which to print the output data.
- Constructing the first few lines of HTML text.

Listing 4 - Begin constructing the HTML output data.

```

        //Establish the type of output
res.setContentType("text/html");

//Get an output stream
PrintWriter out = res.getWriter();

//Construct an html form and send it back to the client
out.println("<html>");
out.println("<head><title>Java4550a</title></head>");
out.println("<body>");

```

Table 5.70**Create raw HTML code for the form**

Listing 5 (p. 2137) begins the construction of the HTML form that is to be returned to the browser. This code creates the first in a series of HTML statements necessary to support the input field and the submit button. (You may need to refer to earlier modules that discussed the format of an HTML form in order to understand the next few fragments.)

Listing 5 - Begin the HTML code for an HTML form.

```

out.println("<form method='get' action="
+ "\"http://" + hostName + ":8080/Java4550a\">");

```

Table 5.71

The code in Listing 5 (p. 2137) uses the name of the computer on which the server is running (**hostName**) that was obtained and saved earlier to construct the **action** element of the HTML form. This causes the servlet to be suitable for running in a server on an computer with any name. It also makes it possible to access the servlet from other computers on the local area network provided those computers know the name of the computer on which the server is running.

Once again, this is very important information for students enrolled in this course.

This code produced the term **dell8700** in Figure 3 (p. 2133) because the server was running on a computer named dell8700 when the screen shot was taken.

This fragment results in HTML code that causes a **GET** request to be sent to the HTTP server containing field data as a parameter whenever the user presses the **submit** button

The input field and the submit button

Listing 7 (p. 2138) places a line of instructional text on the browser screen.

It also creates the HTML code necessary to place an *input* field and a *submit* button on the form that will be displayed on the screen as shown in Figure 1 (p. 2131) .

Listing 6 - An input field and a submit button.

```
out.println("<p>Enter a name and press the button</p>");
out.println("<p>Name: <input type=\"text\" name="
           + "\"firstName\"/></p>");
out.println("<input type=\"submit\" value="
           + "\"Submit Name\"/>")
```

Table 5.72**The list of names**

Listing 7 (p. 2138) provides a line of introductory text for the list of names to be displayed on the screen. The first time the form appears on the screen, the value stored in the **name** variable is null, and the word **Empty** is displayed as shown in Figure 1 (p. 2131) . Later on after multiple requests, the list will be populated as shown in Figure 2 (p. 2132) .

Listing 7 - Beginning of the list of names.

```
out.println("<p>Your list of names is:<br/>");
if(name == null){
    out.println("Empty</p>");
} //end if
```

Table 5.73**Create new hidden fields for historical data**

Listing 2 (p. 2135) retrieved all of the data in the hidden fields on the form and saved that data in a **String** array named **items** .

If that array contains data, the code in Listing 8 (p. 2139) performs two actions using the data from each of the elements in the array:

- Display the historical data stored in those element of the array.
- Create new hidden fields in the HTML output form under construction and place the data values from the array in those hidden fields.

Listing 8 - Display the historical data and also save it on the browser.

```

    if(items != null){
    for(int i = 0; i < items.length; i++){
        //Display names previously saved in hidden fields
        out.println(items[i] + "<br/>");
        //Save the names in hidden fields on form currently
        // under construction.
        out.println("<input type=\"hidden\" name=\"item\" "
                    + "value=\"" + items[i] + "\">");
    }//end for loop
    }//end if

```

Table 5.74**Limited persistence**

Thus, the historical data is passed forward from the hidden fields of one HTML form to the hidden fields of the next HTML form. All of the historical data resides on the HTML form in the browser cache in the client computer. However, that is not a location that provides long-term persistence, so this scheme for session tracking has limited persistence.

Create new hidden field for new data

Listing 3 (p. 2135) retrieved the field value submitted by the browser and saved that value in a variable named **name** .

If that variable contains data, the fragment in Listing 9 (p. 2139) performs two actions using the data stored in the variable.

- Display the value at the end of the list of names.
- Create a new hidden field in the HTML output form under construction and place the value from the variable in that hidden field.

Listing 9 - Display most recent value and also store it on the browser.

```

    if(name != null){
    //Display name submitted with current GET request
    out.println(name + "<br/>");
    //Save name submitted with current GET request in a
    // hidden field on the form currently under
    // construction
    out.println("<input type=\"hidden\" name=\"item\" "
                + "value=\"" + name + "\">");
    }//end if

```

Table 5.75

Thus, for each new request by the browser, one additional hidden field is added to the HTML form under construction. The new hidden field contains the field value submitted by the browser.

The remaining servlet code

The remainder of the code for the servlet is typical of what you have seen before and can be viewed in the complete listing of the servlet in Listing 16 (p. 2143) .

5.4.5.4.1.2 Tedious and error prone

Writing raw HTML code is not fun even under the best of circumstances. That is why I use a WYSIWYG HTML editor for authoring these modules.

Even for this very simple servlet, the process of constructing the output HTML code using Java `println` statements was very tedious and error prone. Much of the difficulty arises from the fact that Java strings must be enclosed in matching double quotes and all HTML attribute values must also be enclosed in matching double or single quotes. As you can see from Listing 16 (p. 2143) , the requirement to escape double quotes inside Java strings with the backslash character can lead to some very confusing code. (*I suppose it might be less confusing if I were to use single quotes instead of double quotes on HTML attribute values. I will try that in the next module.*)

In any event, the next section presents a JSP version of the same servlet. JSP intermingles HTML code with Java code and greatly reduces the amount of HTML code that must be constructed using Java `println` statements in a servlet. If you are unfamiliar with JSP, you can learn about it in the modules that begin at Java4305: Preface to JSP ¹⁰³ .

5.4.5.4.2 The JSP program

A complete listing of the JSP version of this program is provided in Listing 17 (p. 2146) . I found this JSP version much easier to write than the servlet version discussed above. Admittedly, however, I wrote the servlet version first, so that probably helped to make it easier to write the JSP version.

I wrote all of the HTML code using Microsoft Expression Web 4, which provides both a WYSIWYG capability and a raw HTML editing capability. Once I confirmed that the HTML code was correct and valid, I went back and inserted the JSP tags containing the Java code.

As mentioned earlier, the JSP does not get and use the name of the computer on which it is running. Instead it uses the generic name localhost, which limits the ability to access the JSP from another computer on the network.

5.4.5.4.3 Interesting code fragments

Once again, I will discuss this program in fragments. A complete listing of the program is provided in Listing 17 (p. 2146) .

Create basic web page structure

Listing 10 (p. 2140) shows the HTML code that is roughly equivalent to the Java code in Listing 4 (p. 2137) through Listing 7 (p. 2138) . This code creates the HTML header and the basic structure of the web page shown in Figure 1 (p. 2131) .

Listing 10 - Create basic web page structure.

```
<html>
<head><title>Java4550a</title></head>
<body>

<form method="get" action="http://localhost:8080/Java4550a.jsp">
<p>Enter a name and press the button</p>
<p>Name: <input type="text" name="firstName"/></p>
<input type="submit" value="Submit Name"/>
<p>Your list of names is:<br/>
```

¹⁰³<http://cnx.org/content/m48057/latest/?collection=coll1441/latest>

Table 5.76

A JSP scriptlet

Listing 11 (p. 2141) is a scriptlet containing pure Java code. It begins by getting the data from the request object. Then it deals with the situation where nothing has been entered into the text field in Figure 1 (p. 2131), reporting that the list is empty. It ends with the beginning of a **for** loop that is executed when the array is not empty. Recall that in JSP, Java code blocks can begin in one scriptlet and end in another scriptlet later in the page. That is what is happening here.

Listing 11 - A JSP scriptlet.

```

<%
String[] items = request.getParameterValues("item");
response.setContentType("text/html");

String name = request.getParameter("firstName");
if(name == null){
    out.println("Empty");
} //end if

if(items != null){
    for(int i = 0; i < items.length; i++){
%>

```

Table 5.77

The body of the for loop

Listing 12 (p. 2141) contains the body of the **for** loop that began in Listing 11 (p. 2141). This is a combination of a JSP *expression* tag and raw HTML code to display the new value and also to create and populate a hidden field in the output.

Listing 12 - The body of the for loop.

```

<%= items[i] %> <br/>
<input type="hidden" name="item" value="<%=items[i]%>" />

```

Table 5.78

Another scriptlet

Listing 13 (p. 2142) is another scriptlet containing pure Java code. This scriptlet terminates the **for** loop and the **if** statement that began in Listing 11 (p. 2141). It also begins a new **if** statement to display the new input value and also to create and populate the last hidden field containing the newly received input value.

Listing 13 - Another scriptlet.

```

    <%
    }//end for loop
}//end if

if(name != null){
%>

```

Table 5.79**Another JSP expression tag**

Listing 14 (p. 2142) contains another JSP expression tag that displays the new input value. Listing 14 (p. 2142) also creates and populates the last hidden field with the new input value.

Listing 14 - Another JSP expression tag.

```

    <%= name %> <br/>
<input type="hidden" name="item" value="<%=name%>"/>

```

Table 5.80**Terminating scriptlet and HTML code**

Finally, Listing 15 (p. 2142) shows a scriptlet containing a curly bracket to terminate the if statement that began in Listing 13 (p. 2142) along with raw HTML code to terminate the HTML page.

Listing 15 - Terminating scriptlet and HTML code.

```

    <%
}//end if
%>
</p></form></body></html>

```

Table 5.81**5.4.5.5 Run the programs**

I encourage you to copy the code from Listing 16 (p. 2143) and Listing 17 (p. 2146) Deploy the programs on your own server. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

5.4.5.6 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java4550: Session Tracking using Hidden Fields
- File: Java4550.htm
- Published: 12/22/13
- Revised: 02/07/16

Disclaimers: Financial : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

In the past, unknown individuals have copied my modules from cnx.org, converted them to Kindle books, and placed them for sale on Amazon.com showing me as the author. I neither receive compensation for those sales nor do I know who does receive compensation. If you purchase such a book, please be aware that it is a copy of a module that is freely available on cnx.org and that it was made and published without my prior knowledge.

Affiliation : I am a professor of Computer Information Technology at Austin Community College in Austin, TX.

5.4.5.7 Complete program listings

Listing 16 - The servlet program named Java4550a.java.

```
/*File Java4550a.java, Copyright 1999, R.G.Baldwin
Rev 01/04/14
```

```
The purpose of this program is to illustrate session
tracking through the use of hidden fields.
```

```
Each time the submit button is pressed, this servlet
creates a web page and sends it back to the browser.
The new web page contains the historical data for the
session in hidden fields in the web page.
The following is a typical web page after the names
Tom, Dick, and Harry have been entered.:
```

```
The program also detects the name of the server that it
is running on and uses that name to construct the action
element of a form. In the output shown below, the
servlet was running on a computer named dell8700.
```

```
<html>
<head><title>Java4550a</title></head>
<body>
```

```

<form method="get" action="http://dell18700:8080/Java4550a">
<p>Enter a name and press the button</p>
<p>Name: <input type="text" name="firstName"/></p>
<input type="submit" value="Submit Name"/>
<p>Your list of names is:<br/>
Tom<br/>
<input type="hidden" name="item" value="Tom">
Dick<br/>
<input type="hidden" name="item" value="Dick">
Harry<br/>
<input type="hidden" name="item" value="Harry">
</form></body></html>

5.4.6.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX.

This module contains review questions and answers keyed to the module titled Java4550: Session Tracking using Hidden Fields¹⁰⁵ in the Servlets sub-collection.

Once you study that module, you should be able to answer the review questions in this module.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

5.4.6.3 Questions

5.4.6.3.1 Question 1

True or False?

The HTTP protocol is a very sophisticated protocol that retains historical information from one client request to the next.

Go to answer 1 (p. 2150)

5.4.6.3.2 Question 2

True or False?

The maintenance of historical information during communications on the web is often referred to as "*session tracking*."

Go to answer 2 (p. 2150)

5.4.6.3.3 Question 3

True or False?

There are several different ways to accomplish session tracking with a servlet. One of those ways is commonly known as *hidden fields* .

Go to answer 3 (p. 2150)

5.4.6.3.4 Question 4

True or False?

The hidden fields approach to session tracking has a very long persistence (*days, months, years*) and maintains historical information over many user sessions on a website.

Go to answer 4 (p. 2149)

¹⁰⁴This content is available online at <<http://cnx.org/content/m49590/1.2/>>.

¹⁰⁵<http://cnx.org/content/m48550/latest/?collection=col11441/latest>

5.4.6.3.5 Question 5

True or False?

An HTTP server does not remember historical information from one request to the next.

Go to answer 5 (p. 2149)

5.4.6.3.6 Question 6

True or False?

Servlet code can call the `getParameter` method on the incoming request object to get a reference to a `String` array object containing the `String` values of all incoming hidden fields whose name matches the `String` passed as a parameter to the method.

Go to answer 6 (p. 2149)

5.4.6.3.7 Question 7

True or False?

Servlet code can call the `getParameter` method on the incoming request object to get a reference to a `String` object containing the `String` value of an incoming hidden field whose name matches the `String` passed as a parameter to the method. You should only use this method when you are sure the parameter has only one value. Otherwise, the results may not be what you intended.

Go to answer 7 (p. 2149)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.4.6.4 Answers

5.4.6.4.1 Answer 7

True.

Go back to Question 7 (p. 2148)

5.4.6.4.2 Answer 6

False. Servlet code can call the `getParameterValues` method on the incoming request object to get a reference to a **String** array object containing the **String** values of all incoming hidden fields whose name matches the **String** passed as a parameter to the method.

Go back to Question 6 (p. 2148)

5.4.6.4.3 Answer 5

True.

Go back to Question 5 (p. 2148)

5.4.6.4.4 Answer 4

False. The hidden fields approach to session tracking is generally limited to one session consisting of multiple requests.

Go back to Question 4 (p. 2147)

5.4.6.4.5 Answer 3

True.

Go back to Question 3 (p. 2147)

5.4.6.4.6 Answer 2

True.

Go back to Question 2 (p. 2147)

5.4.6.4.7 Answer 1

False. The HTTP protocol is a relatively simple request/response protocol that does not retain historical information from one client request to the next.

Go back to Question 1 (p. 2147)

5.4.6.5 Miscellaneous

This section contains a variety of miscellaneous information.

5.4.7.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX. The purpose of this module is to explain session tracking using URL rewriting, and to compare a servlet with a JSP to accomplish the same objective.

5.4.7.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.4.7.2.1.1 Figures

- Figure 1 (p. 2152) . The URL for hidden fields.
- Figure 2 (p. 2153) . Servlet output screen.
- Figure 3 (p. 2155) . HTML code created by servlet.

5.4.7.2.1.2 Listings

- Listing 1 (p. 2155) . Beginning of the doGet method.
- Listing 2 (p. 2156) . Get and save URL parameters named item.
- Listing 3 (p. 2156) . Construct the new parameter string.
- Listing 4 (p. 2157) . Concatenate current date and time to new parameter string.
- Listing 5 (p. 2157) . Begin creation of the HTML page.
- Listing 6 (p. 2157) . Construct the hyperlink.
- Listing 7 (p. 2158) . Introductory text.
- Listing 8 (p. 2158) . Display date and time history.
- Listing 9 (p. 2158) . Display the current date and time.
- Listing 10 (p. 2159) . Import necessary packages.
- Listing 11 (p. 2159) . Get data from the old parameter string.
- Listing 12 (p. 2160) . Construct a new parameter string.
- Listing 13 (p. 2160) . Concatenate current date and time to the parameter string.
- Listing 14 (p. 2160) . Create the hyperlink.
- Listing 15 (p. 2162) . Display the list of dates.
- Listing 16 (p. 2163) . The servlet named Java4560a.java
- Listing 17 (p. 2165) . The JSP program named Java4560b.jsp.

5.4.7.3 General background information

A stateless protocol

You learned in earlier modules that the HTTP protocol is a relatively simple request/response protocol that does not retain historical information from one client request to the next. You also learned that historical information can be very important, and the maintenance of historical information is often referred to as "session tracking."

Session tracking

Because session tracking is very important for many web applications, an earlier module ¹⁰⁷ along with this and the next several modules will show you some of the ways that you can accomplish session tracking using servlets and JSP.

Session tracking using URL rewriting

There are several different ways to accomplish session tracking with a servlet. The earlier module ¹⁰⁸ explained session tracking using hidden fields. This module will illustrate how to accomplish session tracking using URL rewriting.

Limited persistence

You learned in the earlier module ¹⁰⁹ that the session tracking scheme using hidden fields is generally limited to one session consisting of multiple requests. You also learned that the scheme is probably not useful for large scale web commerce. However, it might be useful for an online game where the user makes a move and then clicks a **submit** button. The computer needs to remember the entire history of the game, but needn't necessarily remember the history if the user leaves the website by closing the browser page.

The same holds true for session tracking using URL rewriting. Session tracking using URL rewriting provides only limited persistence. While this may seem like a major downside, there is at least one upside for both schemes.

Comparison with cookies

A future module will explain session tracking using cookies. Cookies probably provide the most commonly used scheme for session tracking because cookies can provide persistence over long periods of time. However, there is also a downside to cookies. The user can disable cookies in the browser, which completely defeats the use of cookies for session tracking.

Therefore, if your online game uses cookies for session tracking and the user disables cookies, then your game won't work in that browser. As far as I know, it is not possible for the user to prevent session tracking using either hidden fields or URL rewriting.

A servlet and a JSP

I will explain two different programs that accomplish the same objective in this module. One of the programs is a servlet. The other program is a JSP. You probably need to understand the servlet version in order to really understand the JSP version.

The URL window with hidden fields

If you observed the URL window in your browser while running the hidden-field servlet in the earlier module ¹¹⁰, you probably noticed that after several cycles, the window containing the URL looked something like Figure 1 (p. 2152).

Figure 1 - The URL for hidden fields.

What you see in Figure 1 (p. 2152) is the standard way that HTML forms pass parameters to their HTTP servers using the GET method.

A parameter string

¹⁰⁷<http://cnx.org/content/m48550/latest/?collection=col11441/latest>

¹⁰⁸<http://cnx.org/content/m48550/latest/?collection=col11441/latest>

¹⁰⁹<http://cnx.org/content/m48550/latest/?collection=col11441/latest>

¹¹⁰<http://cnx.org/content/m48550/latest/?collection=col11441/latest>

When the user clicks the **submit** button, a string containing the names and values (*name::value pairs again*) for all of the fields is created and concatenated onto the URL. The string of parameter values is joined to the URL with a "?" character. The individual parameters are separated from one another with the ampersand character.

Recall that for the servlet in the earlier module ¹¹¹, the field named **firstName** was the visible field in which the user entered a name. The fields named **item** were hidden fields that were created and populated with historical data when the servlet generated the HTML form for return to the client. You can see parameters with both of these names in Figure 1 (p. 2152) .

The parameters are accessible by the servlet

It doesn't really matter how these parameter names and values come to be concatenated onto the URL. As far as the servlet is concerned, their values are accessible using the methods **getParameter()** and **getParameterValues()** .

This suggests that in some cases, it might be beneficial for the servlet to save the historical data by concatenating it onto a URL referenced in the HTML page before returning the page to the client. That is one of the ways that URL rewriting can be used to implement session tracking.

5.4.7.4 Discussion and sample code

As I mentioned earlier, I will present a servlet and a JSP program where both are designed to achieve the same objective. This will make it possible for you to compare the two programming styles.

Both programs are designed to illustrate the concept of URL rewriting and are not intended to have any practical value in their own right.

I will explain both programs in fragments. A complete listing of the servlet named **Java4560.java** is provided in Listing 16 (p. 2163) . A complete listing of the JSP program named **Java4560b.jsp** is provided in Listing 17 (p. 2165) .

5.4.7.4.1 The servlet program

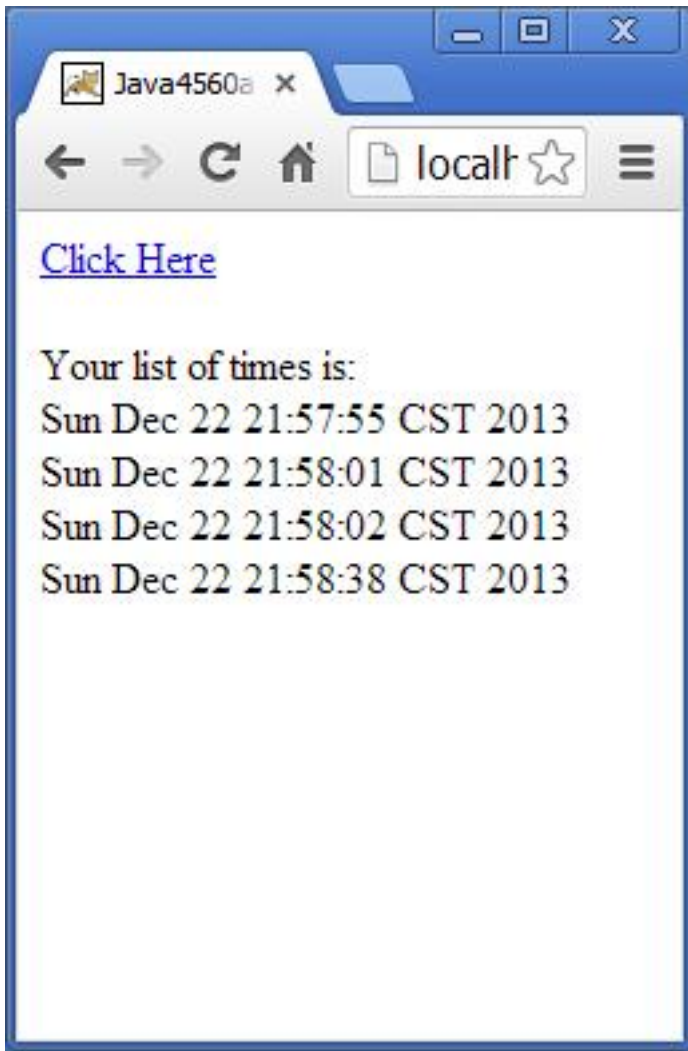

The servlet named **Java4560a.java** illustrates session tracking using URL rewriting. In this servlet, parameters containing the historical data are added to the servlet's URL each time the servlet generates a new HTML page. The updated URL is included as a hyperlink in the new web page.

The servlet output

Each time the servlet is called, it creates and displays an HTML page on the client screen similar to that shown in Figure 2 (p. 2153) .

Figure 2 - Servlet output screen.

¹¹¹<http://cnx.org/content/m48550/latest/?collection=col11441/latest>

The page displays:

- A hyperlink to the servlet URL labeled **Click Here**
- A list of the dates and times on which the user previously called the servlet by clicking on the hyperlink.

A get request

Each time the user clicks the hyperlink, the client sends a GET request to the server. The GET request calls the servlet, which determines the current date and time in milliseconds relative to January 1, 1970. An HTML page is created and sent back to the client.

Update the parameter string

The current date and time in milliseconds is added as a parameter named **item** to the servlet URL referenced by the hyperlink in the newly-created HTML page. In addition to the current date and time, the values of the previous dates and times on which the user called the servlet are retrieved from the incoming URL parameter string and appended to the new URL parameter string.

In other words, the parameter string values for each successive URL that is generated match those of the previous URL. In addition, a new parameter value is added that represents the current date and time.

Embed historical data in the web page

In a manner similar to session tracking using hidden fields, the historical data is saved by embedding it in the new HTML page that is returned to the client. There is no requirement to save the historical data in

a database or in the server's file system.

Figure 3 (p. 2155) shows the HTML source code that corresponds to the web page shown in Figure 2 (p. 2153).

Figure 3 - HTML code created by servlet.

```

1 <html>
2 <head><title>Java4560a</title></head>
3 <body>
4 <a href='http://localhost:8080/Java4560a?
  item=1387771075185&item=1387771081455&item=1387771082522&
  item=1387771118708'>Click Here</a>
5 <br/><br/>Your list of times is:<br/>
6 Sun Dec 22 21:57:55 CST 2013<br/>
7 Sun Dec 22 21:58:01 CST 2013<br/>
8 Sun Dec 22 21:58:02 CST 2013<br/>
9 Sun Dec 22 21:58:38 CST 2013<br/>
10 </body></html>
11

```

The URL parameter string

The most interesting thing in Figure 3 (p. 2155) is the content of Line 4. (Note that Line 4 is wrapped and appears as three physical lines in Figure 3 (p. 2155).) Each large numeric value that you see in Line 4 is the number of milliseconds since January 1, 1970 for a particular date and time. These values in milliseconds are translated into actual dates and times and shown in Lines 6 through 9.

No special software requirements

This approach places no special requirements on the server software other than the ability to support Java servlets. The approach should be compatible with all browsers that support hyperlinks.

5.4.7.4.1.1 Interesting code fragments

Beginning of the doGet method

As mentioned earlier, I will explain this program in fragments. Listing 1 (p. 2155) shows the beginning of the controlling class and the beginning of the `doGet` method. You have seen code like this before, so I won't discuss it further.

Listing 1 - Beginning of the doGet method.

continued on next page

```

import java.io.*;
import java.util.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class Java4560a extends HttpServlet{
    public void doGet(HttpServletRequest request,
                      HttpServletResponse response)
                      throws ServletException, IOException{

```

Table 5.83

Get and save URL parameters named item

An HTTP URL can have multiple parameters with the same name. In this case, all of the parameters are named **item** . Listing 2 (p. 2156) gets the values stored in all of the parameters named **item** and saves them in a **String** array named **items** .

(Each time the servlet is called, the size of the list of parameters increases by one.)

The fragment also instantiates and initializes a **String** object used later to construct a new parameter string for the URL.

Listing 2 - Get and save URL parameters named item.

```

String parameters = "?";
String[] items = request.getParameterValues("item");

```

Table 5.84

Construct the new parameter string

Listing 3 (p. 2156) uses the parameter values from the old parameter string to construct a new parameter string. The new parameter string will later be concatenated to the URL for the servlet.

Listing 3 - Construct the new parameter string.

```

if(items != null){
    for(int i = 0; i < items.length; i++){
        parameters = parameters + "item=" + items[i] + "&";
    } //end for loop
} //end if

```

Concatenate current date and time to new parameter string

Listing 4 (p. 2157) gets the current date and time in milliseconds and saves it in a **long** variable named **theDate** . Then it concatenates the current date and time in milliseconds onto the new parameter string that was constructed in Listing 3 (p. 2156) .

Listing 4 - Concatenate current date and time to new parameter string.

```

    long theDate = new Date().getTime();
    parameters = parameters + "item=" + theDate;

```

Table 5.85**Begin creation of the HTML page**

Listing 5 (p. 2157) begins the creation of the output HTML page. You have seen code like this before, so I won't discuss it further at this point.

Listing 5 - Begin creation of the HTML page.

```

    //Establish the type of output
    response.setContentType("text/html");

    //Get an output stream
    PrintWriter out = response.getWriter();

    //Construct an HTML page and send it back to the client
    out.println("<html>");
    out.println("<head><title>Java4560a</title></head>");
    out.println("<body>");

```

Table 5.86**Construct the new hyperlink**

Listing 6 (p. 2157) constructs the hyperlink containing the URL for the servlet. Note that the hyperlink references a URL that includes the parameter string constructed above.

If you compile and run this servlet, you may need to substitute the name of your server in place of my server.

Listing 6 - Construct the hyperlink.

```

    out.println("<a href='http://localhost:8080/Java4560a"
        + parameters + "'>Click Here</a>");

```

Table 5.87**Introductory text**

Listing 7 (p. 2158) provides a line of introductory text for the list of dates and times to be displayed on the screen.

Listing 7 - Introductory text.

```
out.println("<br/><br/>Your list of times is:<br/>");
```

Table 5.88**Display date and time history**

Listing 2 (p. 2156) retrieved all of the data in the incoming URL parameters and saved that data in a **String** array named **items** .

If that array contains data, Listing 8 (p. 2158) displays the date and time for each element in the array.

The parameter values in milliseconds are first converted from **String** to **long** . Each of the **long** values is then used to instantiate a new **Date** object, which is displayed in the format shown in Figure 2 (p. 2153) .

Listing 8 - Display date and time history.

```
if(items != null){
for(int i = 0; i < items.length; i++){
    long millis = Long.parseLong(items[i]);
    out.println("" + new Date(millis) + "<br/>");
} //end for loop
} //end if
```

Table 5.89

*(Hopefully you already understand the relationship between the overridden **toString** method of the **Date** class and the format resulting from passing a **Date** object's reference to the **println** method. If not, see *Ap0005: Preface to OOP Self-Assessment*¹¹² and the modules following that one.)*

Display the current date and time

Listing 4 (p. 2157) obtained the current date and time in milliseconds and saved it in a variable named **theDate** . Listing 9 (p. 2158) uses that value to instantiate and display a new **Date** object reflecting the current date and time.

Listing 9 - Display the current date and time.

```
out.println("" + new Date(theDate) + "<br/>");
out.println("</body></html>");//finish HTML page
```

Table 5.90

Listing 9 (p. 2158) also creates the HTML code necessary to finish the HTML page.

¹¹²<http://cnx.org/content/m45252/latest/?collection=col11441/latest>

5.4.7.4.2 The JSP program

I will also discuss the JSP program named **Java4560b.jsp** in fragments. A complete listing of the program is provided in Listing 17 (p. 2165) .

5.4.7.4.2.1 Interesting code fragments

Import necessary packages

Listing 10 (p. 2159) shows the necessary import directives plus the beginning of the HTML page.

Listing 10 - Import necessary packages.

```
<%@ page import='java.util.*,java.io.*' %>

<html>
<head><title>Java4560b</title></head>
<body>
```

Table 5.91

There's nothing new in Listing 10 (p. 2159) with the possible exception of the format of the import directives. The format is different from the format used in regular Java code. (See Listing 1 (p. 2155) .)

Some packages are imported automatically

Recall from Java4307: Servlets and JSP ¹¹³ that it is not necessary to import **javax.servlet** and **javax.servlet.http** . Those two packages are automatically imported by the JSP container on the server. No page directive import settings are required for using the classes defined in these packages.

Get data from the old parameter string

Listing 11 (p. 2159) shows the beginning of a scriptlet containing pure Java code.

Listing 11 - Get data from the old parameter string.

```
<%
String parameters = "?";
String[] items = request.getParameterValues("item");
```

Table 5.92

The code in Listing 11 (p. 2159) declares and initializes a **String** that will be used later to construct a new parameter string.

Listing 11 (p. 2159) also gets and saves the values of all of the parameters from the old parameter string named *"item"* .

Construct a new parameter string

Listing 12 (p. 2160) constructs a new parameter string containing the names and values of all the parameters named *"item"* in the old parameter string. (A parameter for the current date and time will be concatenated later.)

¹¹³<http://cnx.org/content/m48284/latest/?collection=col11441/latest>

Listing 12 - Construct a new parameter string.

```

if(items != null){
    for(int i = 0; i < items.length; i++){
        parameters = parameters + "item=" + items[i] + "&";
    } //end for loop
} //end if

```

Concatenate current date and time to the parameter string

Listing 13 (p. 2160) gets the current date and time in milliseconds and concatenates it to the new parameter string with the name *"item"* .

Listing 13 - Concatenate current date and time to the parameter string.

```

    long theDate = new Date().getTime();
    parameters = parameters + "item=" + theDate;

    response.setContentType("text/html");
%%>

```

Table 5.93

Listing 13 (p. 2160) also sets the output content type to *"text/html"* .

Finally, Listing 13 (p. 2160) signals the end of the scriptlet that began in Listing 11 (p. 2159) .

Create the hyperlink

Listing 14 (p. 2160) uses a JSP *expression* tag along with raw HTML code to create the hyperlink shown near the top of the page in Figure 2 (p. 2153) .

Listing 14 - Create the hyperlink.

```

<a href='http://localhost:8080/Java4560b.jsp<%=parameters%>'>
Click Here</a>

<br/><br/>Your list of times is:<br/>

```

Listing 14 (p. 2160) also uses raw HTML code to create the line of text that appears immediately above the list of dates in Figure 2 (p. 2153) .

Display the list of dates

Listing 15 (p. 2162) shows another scriptlet containing pure Java code. The first six lines of code display the historical date and time information. The next line of code displays the current date and time.

Listing 15 - Display the list of dates.

```

<%
if(items != null){
    for(int i = 0; i < items.length; i++){
        long millis = Long.parseLong(items[i]);
        out.println("" + new Date(millis) + "<br/>");
    }//end for loop
} //end if

out.println("" + new Date(theDate) + "<br/>");
out.println("</body></html>");
%%>

```

Table 5.94

The last line of code creates the HTML elements necessary to finish the page.

A choice

I could have broken this scriptlet into two or more scriptlets using raw HTML code in between to display the material. However, I decided that it was simpler in this case to use Java **println** statements to display the material than it would have been to break it up and use interspersed HTML code.

5.4.7.5 Run the programs

I encourage you to copy the code from Listing 16 (p. 2163) and Listing 17 (p. 2165) . Install the programs on your server and run them. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

5.4.7.6 Miscellaneous

This section contains a variety of miscellaneous information.

5.4.8.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX. The purpose of this module is to explain session tracking using cookies, and to compare a servlet with a JSP to accomplish the same objective.

If you haven't already done so, I strongly recommend that you study [Java4370: Cookies with JSP](#)¹¹⁵ before continuing with this module. Dr. Martinez explains many aspects of cookies in that module. Most of those aspects apply to both JSP and servlets and many of them won't be repeated in this module.

5.4.8.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.4.8.2.1.1 Figures

- Figure 1 (p. 2167) . Output from the servlet program.
- Figure 2 (p. 2167) . Output from the JSP program.
- Figure 3 (p. 2170) . Description of the Cookie constructor.

5.4.8.2.1.2 Listings

- Listing 1 (p. 2171) . Beginning of the doGet method.
- Listing 2 (p. 2171) . Construct a unique session ID.
- Listing 3 (p. 2172) . Get all of the cookies into an array of type Cookie.
- Listing 4 (p. 2172) . Get and save submitted value.
- Listing 5 (p. 2172) . Create a new session ID cookie.
- Listing 6 (p. 2173) . Create, name, and populate a new Cookie object.
- Listing 7 (p. 2174) . Familiar code.
- Listing 8 (p. 2174) . Get and display cookie names and values.
- Listing 9 (p. 2175) . Display currently submitted field value.
- Listing 10 (p. 2176) . The servlet program named Java4570a.java.
- Listing 11 (p. 2178) . The JSP program named Java4570b.jsp.

¹¹⁵<http://cnx.org/content/m48091/latest/?collection=col11441/latest>

5.4.8.3 General background information

5.4.8.3.1 Program output

I will explain a servlet program and present a comparable JSP program in this module. The purpose is to show you how to write servlets that use cookies for session tracking and to make it possible to compare a servlet and a JSP that both achieve the same objective.

The servlet output

Figure 1 (p. 2167) shows the output produced by requesting the servlet from the localhost server using the Chrome browser and then submitting the names Tom, Dick, and Harry using the input text field and the submit button. I will refer back to this Figure later while explaining the servlet code.

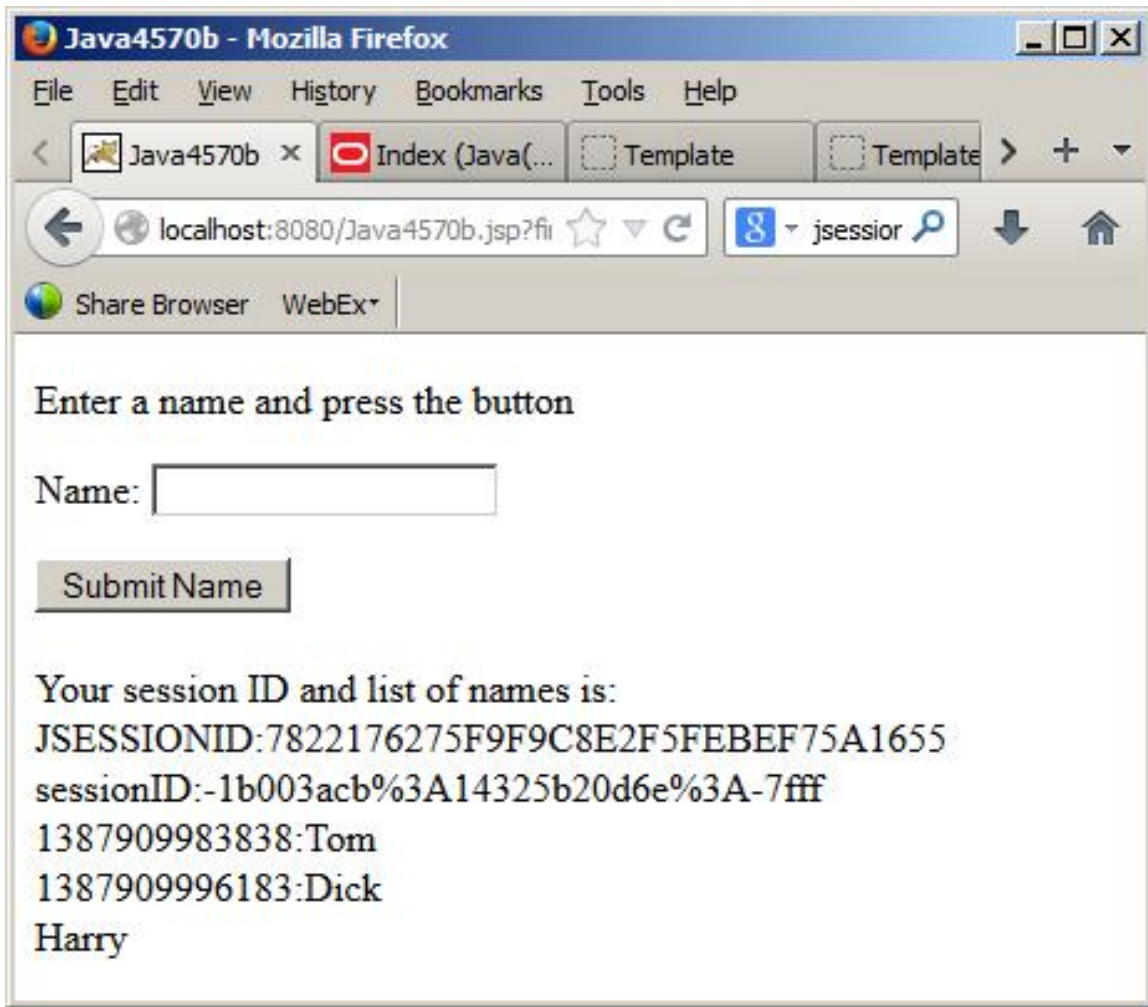

Figure 1 - Output from the servlet program.

The JSP output

Figure 2 (p. 2167) shows the output produced by requesting the JSP from the localhost server using the Firefox browser and then submitting the names Tom, Dick, and Harry using the input text field and the submit button. I will refer back to this Figure later while explaining the JSP code.

Figure 2 - Output from the JSP program.

(The main difference between Figure 1 (p. 2167) and Figure 2 (p. 2167) is the line that begins with `JSESSIONID` in Figure 2 (p. 2167). Also Figure 1 (p. 2167) is displayed in a Chrome browser and Figure 2 (p. 2167) is displayed in a Firefox browser.)

5.4.8.3.2 What are cookies?

Cookies are information that is created by a web application and stored on the client machine by the browser. Under certain conditions, this information is sent to the HTTP server whenever a request is sent from the client to the server.

Used for session tracking

Cookies are widely used by various server-side programming techniques for session tracking. Java provides classes and methods designed to allow you to use cookies in your servlets.

Which server receives a cookie?

By default, cookies are sent only to the host that caused them to be saved. Methods can be called to set attributes for each cookie that determine which servers will receive the cookie. For example, the `setDomain` method can be used to specify a domain pattern indicating which servers should receive a cookie.

By default, cookies are sent to the page that set the cookie and to all the pages in that directory or under that directory. This also can be modified by calling the `setPath` method on the cookie.

What is the life expectancy of a cookie?

Also by default, a cookie expires when the browser exits. The `setMaxAge` method can be called to override the default and specify the maximum age of the cookie in seconds. The cookie will expire when the maximum age has been reached. The parameter to this method is an `int` so the maximum age of a cookie can be a very large number of seconds. (*The maximum positive value of Java type `int` is 2,147,483,647. If I did the arithmetic correctly, that is about 68 years.*)

Comments in a cookie

The `setComment` method can be used to provide a comment with the cookie. The browser may elect to make this information available to the user.

Name and value of a cookie

The constructor sets the name and value of a cookie when the `Cookie` object is instantiated. The `setValue` method can be used to assign a new value to the cookie after it is instantiated.

Other attributes

There are a few other attributes that can be set as well. You can read about them in the Java(TM) EE 7¹¹⁶ documentation.

Cookies can be disabled

CAUTION: The user can disable cookies in most, and perhaps all browsers. As a result, the user can defeat session tracking using cookies.

Therefore, unless you can be certain that all of your clients will operate with cookies enabled, the use of cookies for session tracking may not be satisfactory in all cases. (*The fallback position may be the less-persistent `Hidden Fields` and/or `URL Rewriting methods` of session tracking.*)

5.4.8.3.3 The Java Cookie class

The `Cookie` class represents a cookie that can be used for session management with the HTTP protocol.

Cookies are used to cause *user agents* such as web browsers to store small amounts of state associated with a user's web browsing activities.

Applications

Common applications for cookies include:

- Storing user preferences
- Automating low security user signon facilities, and
- Helping collect data used for "shopping cart" applications.

Names, values, and attributes

Each cookie has a name and a single value (*a `name::value pair`*). As mentioned earlier, it may have optional attributes, including:

- A comment presented to the user
- Path and domain qualifiers to specify which hosts can see the cookie
- A maximum age, and
- A version.

Sending cookies to the browser

In the Java API, cookies are saved one at a time into such HTTP response headers, using the `addCookie` method.

According to the Java documentation¹¹⁷, The browser is expected to support 20 cookies for each web server, 300 cookies total, and may limit cookie size to 4 KB each.

Servers assign cookies, using fields added to HTTP *response* headers.

Retrieving cookies from the browser

Cookies are passed from the browser to the server using fields added to HTTP *request* headers.

¹¹⁶<http://docs.oracle.com/javase/7/api/index.html?javax/servlet/http/Cookie.html>

¹¹⁷<http://docs.oracle.com/javase/7/api/index.html?javax/servlet/http/Cookie.html>

In the Java API, HTTP cookies are retrieved using the `getCookies` method. This method returns all of the cookies found in the request sent by the client.

Description of the Cookie constructor

An abbreviated description of the constructor for the `Cookie` class is shown in Figure 3 (p. 2170) .

<p>Figure 3 - Description of the Cookie constructor.</p> <pre>public Cookie(String name, String value) Constructs a cookie with the specified name and value. The name of a cookie cannot be changed once the cookie has been created. The value can be anything the server chooses to send. The cookie's value can be changed after creation with the <code>setValue</code> method. Parameters: <ul style="list-style-type: none"> • name - the name of the cookie • value - the value of the cookie </pre>
--

Table 5.95

5.4.8.4 Discussion and sample code

5.4.8.4.1 The servlet program

The name of the servlet program is **Java4570** I will discuss this program in fragments. A complete listing of the program is provided in Listing 10 (p. 2176) .

Displays an HTML form

Each time the servlet is called, it displays an HTML form on the client screen as shown in Figure 1 (p. 2167) . The form contains:

- An input field for submitting a name
- A submit button
- A list of previously submitted names
- Some static text

A unique session ID

The first time the servlet is called by a given browser, code written into the servlet creates a unique session ID and stores it in a cookie on the browser. This session ID is not used for any purpose in this sample program. It is included in the servlet simply to show how to create and save a unique session ID.

A cookie containing the submitted value

Each time the servlet is called, it creates a cookie containing the field value submitted by the user and stores it on the browser.

When the servlet is called, it gets all of the cookie information stored on the browser and displays that information on the client screen as shown in Figure 1 (p. 2167) . The display includes the unique session ID and all of the field values submitted by the user during that session.

The maximum age of the cookies

The cookie containing the session ID is deleted when the browser is exited.

The maximum age for all of the other cookies is set to 60 seconds. Therefore, if you submit some names, wait more than 60 seconds, and then submit some more names, the first batch of names submitted will have expired and will have disappeared from the list.

The lifetime of a session

A session doesn't end just because the user visits another page. If the user returns to the **Java4570** servlet without exiting the browser, the cookies written by **Java4570** that have not yet expired will continue to exist on the browser and the session will continue.

Also, if the user exits and then restarts the browser and calls the servlet, the cookies that have not yet expired will continue to exist and will be displayed when the server responds to the request. Thus, a session being tracked by cookies with a long maximum age can persist over long periods of time, even when the computer has been shut down and restarted. (*Many web sites will remember you on the same computer using the same browser over days, months, and even years.*)

5.4.8.4.1.1 Interesting code fragments

Beginning of the doGet method

Listing 1 (p. 2171) shows the beginning of the controlling class and the beginning of the **doGet** method. You have seen code like this before, so I won't discuss it further in this module.

Listing 1 - Beginning of the doGet method.

```
public class Java4570a extends HttpServlet{
    public void doGet(HttpServletRequest request,
                      HttpServletResponse response)
                      throws ServletException, IOException{
```

Table 5.96

Construct a unique session ID

Listing 2 (p. 2171) constructs a unique session ID that is later written into a cookie on the browser.

Listing 2 - Construct a unique session ID.

```
String uid = new java.rmi.server.UID().toString();
String sessionID = java.net.URLEncoder.encode(uid);
```

Table 5.97

A UID object

The first step is to get a **String** representation of a **UID** object. According to the documentation, the **UID** class is an *"Abstraction for creating identifiers that are unique with respect to the host on which it is generated."*

Some cleanup is required

The second step is to call the **encode** method of the **URLEncoder** class to convert the string into a MIME format called the *"x-www-form-urlencoded"* format. This ensures that the identifier can be reliably transmitted between the server and the client and that it will contain only those characters that are acceptable for saving in a cookie (*see documentation on the **setValue** method of the **Cookie** class for more information*) .

To convert the **String** , each character is examined and modified as follows:

- The ASCII characters 'a' through 'z', 'A' through 'Z', and '0' through '9' remain the same.
- The space character is converted into a plus sign '+'.
- All other characters are converted into the 3-character string "%xy", where xy is the two-digit hexadecimal representation of the lower 8-bits of the character.

A typical session identifier created by this process might appear as follows:

```
1cce64%3Ad69878ccf0%3A-7ff9
```

Get all of the cookies into an array of type `Cookie`

Listing 3 (p. 2172) calls the `getCookies` method of the incoming `HttpServletRequest` object to get and save the cookies submitted by the browser. The values of the cookies will be displayed later.

Listing 3 - Get all of the cookies into an array of type `Cookie`.

```
Cookie[] cookies = request.getCookies();
```

Table 5.98

Get and save submitted value

As in the sample programs in earlier modules, Listing 4 (p. 2172) gets and saves the field value submitted by the client.

Listing 4 - Get and save submitted value.

```
String name = request.getParameter("firstName");
response.setContentType("text/html");
```

Table 5.99

Listing 4 (p. 2172) also establishes the type of output.

Create a new session ID cookie

Because cookies are sent to the browser using HTTP headers, they should be added to the response before you send any content.

If no cookies were submitted by the client with the request, this is interpreted by this servlet to be the beginning of the session. A new `Cookie` object is instantiated containing the session ID value created above along with the name of the cookie: `sessionID` .

Then the cookie is sent to the client's browser by calling the `addCookie` method on the outgoing `HttpServletResponse` object as shown in Listing 5 (p. 2172) .

Listing 5 - Create a new session ID cookie.

continued on next page

```
if(cookies == null){
    Cookie newCookie = new Cookie("sessionID",sessionID);
    response.addCookie(newCookie);
} //end if

PrintWriter out = response.getWriter();
```

Table 5.100

Listing 5 (p. 2172) also gets an output stream using code that you have seen in earlier modules.

Create, name, and populate a new Cookie object

Listing 6 (p. 2173) instantiates a **Cookie** object containing the field value submitted by the client and sends that cookie back to the browser for storage.

Listing 6 - Create, name, and populate a new Cookie object.

```
if(name != null){
    String cookieName = "" + new Date().getTime();
    Cookie newCookie = new Cookie(cookieName, name);
    newCookie.setMaxAge(60);
    response.addCookie(newCookie);
} //end if
```

Table 5.101

Unique names for cookies

Unless delineated by path information, each cookie needs a unique name in addition to its value. Assuming that successive calls to this servlet will be separated in time by at least one millisecond, unique names can be created by using the current date and time in milliseconds. That mechanism was used in Listing 6 (p. 2173) to create unique cookie names. The **getTime** method of the **Date** class returns the date and time in milliseconds represented by a **Date** object. The **Date** object in Listing 6 (p. 2173) encapsulates the current date and time. You can see those times represented in milliseconds in the list of cookies in Figure 1 (p. 2167) .

On the other hand, a servlet that creates two or more Cookie objects could easily create more than one cookie during each one-millisecond interval. In that case, you should probably use something like the code in Listing 2 (p. 2171) to create unique cookie names.

Familiar code

Listing 7 (p. 2174) contains code that is very similar to code discussed in earlier modules, so I won't discuss it further here. The fragment is being included here for continuity.

Listing 7 - Familiar code.

```

        //Construct an html form and send it back to the client
out.println("<html>");
out.println("<head><title>Java4570a</title></head>");
out.println("<body>");

//Substitute the name of your server in
// the following statement.
out.println("<form method='get' action="
            + "'http://localhost:8080/Java4570a'>");
out.println("<p>Enter a name and press the button</p>");
out.println("<p>Name: <input type='text' name="
            + "'firstName' /></p>");
out.println("<input type='submit' value="
            + "'Submit Name' />");

out.println(
    "<br/><br/>Your session ID and list of names is:<br/>");
if(name == null){
    out.println("Empty<br/>");
} //end if

```

Table 5.102**Get and display cookie names and values**

Listing 8 (p. 2174) calls the `getName` and `getValue` methods of the `Cookie` class to get and display the names and values of each of the cookies saved earlier in the array of cookies.

The first value displayed should be the session ID that was stored in the first cookie saved. The remaining items in the list should be the field input values previously submitted by the user each time the servlet was called but not including the field input value for this invocation of the servlet.

Listing 8 - Get and display cookie names and values.

```

    if(cookies != null){
for(int i = 0; i < cookies.length; i++){
    out.println(cookies[i].getName() + ":" +
                cookies[i].getValue() + "<br/>");
} //end for loop
} //end if

```

Table 5.103

The output from Listing 8 (p. 2174) is shown by the `sessionID` line and the lines for Tom and Dick in Figure 1 (p. 2167). (*The output from Listing 8 (p. 2174) does not include the line for Harry.*) The large numeric values to the left of Tom and Dick are the cookie names based on the number of milliseconds since January 1, 1970.

Display currently submitted field value

Listing 9 (p. 2175) displays the field value (*Harry*) submitted by the user for the current invocation of the servlet. This value is displayed at the end of the list as shown in Figure 1 (p. 2167) . Note that there is no cookie name associated with Harry in Figure 1 (p. 2167) . This value was not extracted from a named cookie for display. However, it will be displayed with a cookie name if the user calls the servlet again with a new field value before the cookie with the value Harry expires.

Listing 9 - Display currently submitted field value.

```
    if(name != null){
        out.println(name + "<br/>");
    }//end if
```

Table 5.104

The remaining code is typical of what you have seen in earlier modules. You can view that code in Listing 10 (p. 2176) .

5.4.8.4.2 The JSP program

If you understand the explanation of the servlet code given above and you have understood the explanations of JSP code provided in earlier modules, you should have no difficulty understanding the JSP code provided in Listing 11 (p. 2178) . Therefore, I won't bore you with a detailed explanation of that code. The JSP code is provided simply for comparison with the servlet code.

However, there is one point that is worth noting. If you compare Figure 2 (p. 2167) showing the JSP output with Figure 1 (p. 2167) showing the servlet output, you will see that the JSP output contains an extra cookie named **JSESSIONID** . This is a unique session ID value that is automatically created by the JSP container. When writing servlets, you need to take the necessary steps to create a unique session ID. However, when writing JSP, that task is handled automatically for you so there is no need to create your own unique session ID.

5.4.8.5 Run the programs

I encourage you to copy the code from Listing 10 (p. 2176) and Listing 11 (p. 2178) . Install the programs on your server. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

5.4.8.6 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java4570: Session Tracking using Cookies
- File: Java4570.htm
- Revised: 02/07/16

Disclaimers: Financial : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

In the past, unknown individuals have copied my modules from cnx.org, converted them to Kindle books, and placed them for sale on Amazon.com showing me as the author. I neither receive compensation for those sales nor do I know who does receive compensation. If you purchase such a book, please be aware that it is a copy of a module that is freely available on cnx.org and that it was made and published without my prior knowledge.

5.4.8.7 Complete program listing

Listing 10 - The servlet program named Java4570a.java.

```

/*File Java4570a.java, Copyright 1999, R.G.Baldwin
Rev 12/24/13
The purpose of this program is to illustrate session
tracking through the use of cookies.

Each time the servlet is called, it displays an html
form on the client screen. The form contains:
  An input field for submitting a name
  A submit button
  A list of previously submitted names

The first time the servlet is called, it creates a
unique session ID and stores it in a cookie on the browser.

Each time the servlet is called, it creates a cookie
containing the name submitted by the user and stores it
on the browser.

- Miscellaneous (p. 2185)

5.4.9.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX.

This module contains review questions and answers keyed to the module titled Java4570: Session Tracking using Cookies¹¹⁹ in the Servlets sub-collection.

Once you study that module, you should be able to answer the review questions in this module.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

5.4.9.3 Questions

5.4.9.3.1 Question 1

True or False?

Cookies are information that is created by a web application and stored on the HTTP server. Under certain conditions, this information is retrieved and used by the HTTP server whenever a request is sent from the client to the server.

Go to answer 1 (p. 2184)

5.4.9.3.2 Question 2

True or False?

Cookies are widely used by various server-side programming techniques for session tracking. Java provides classes and methods designed to allow you to use cookies in your servlets.

Go to answer 2 (p. 2184)

5.4.9.3.3 Question 3

True or False?

Any HTTP server can obtain cookies from a browser regardless of the server that created the cookie.

Go to answer 3 (p. 2184)

5.4.9.3.4 Question 4

True or False?

By default, a cookie expires 24 hours after it is created.

Go to answer 4 (p. 2184)

¹¹⁸This content is available online at <<http://cnx.org/content/m49593/1.2/>>.

¹¹⁹<http://cnx.org/content/m48571/latest/?collection=col11441/latest>

5.4.9.3.5 Question 5

True or False?

The **setMaxAge** method can be called to override the default and specify the maximum age of a cookie in minutes. The cookie will expire when the maximum age has been reached.

Go to answer 5 (p. 2184)

5.4.9.3.6 Question 6

True or False?

The **setMaxAge** method can be called to override the default and specify the maximum age of a cookie in seconds. The parameter to the **setMaxAge** method is an **int** so the maximum age of a cookie can be years.

Go to answer 6 (p. 2184)

5.4.9.3.7 Question 7

True or False?

The **setComment** method can be used to provide a comment with the cookie. The browser may elect to make this information available to the user.

Go to answer 7 (p. 2184)

5.4.9.3.8 Question 8

True or False?

The constructor sets the name and value of a cookie when the **Cookie** object is instantiated. The **setValue** method can be used to assign a new value to the cookie after it is instantiated.

Go to answer 8 (p. 2184)

5.4.9.3.9 Question 9

True or False?

The **JavaCookie** class represents a cookie that can be used for session management with the HTTP protocol.

Go to answer 9 (p. 2184)

5.4.9.3.10 Question 10

True or False?

Each cookie has a name and a single value (*a name::value pair*) . It may have optional attributes, including:

- A comment
- Path and domain qualifiers to specify which hosts can see the cookie
- A maximum age
- A version.

Go to answer 10 (p. 2183)

5.4.9.3.11 Question 11

True or False?

Servers assign cookies, using fields added to HTTP *response* headers. In the Java API, cookies are saved one at a time into HTTP response headers, using the **addCookie** method.

Go to answer 11 (p. 2183)

5.4.9.3.12 Question 12

True or False?

Cookies are passed from the browser to the server using fields added to HTTP *request* headers.

In the Java API, HTTP cookies are retrieved, one at a time, using the **getCookies** method.

Go to answer 12 (p. 2183)

5.4.9.3.13 Question 13

True or False?

Because cookies are sent to the browser using HTTP headers, they should be added to the response before you send any content.

Go to answer 13 (p. 2183)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.4.9.4 Answers

5.4.9.4.1 Answer 13

True.

Go back to Question 13 (p. 2182)

5.4.9.4.2 Answer 12

False.

Cookies are passed from the browser to the server using fields added to HTTP *request* headers.

In the Java API, HTTP cookies are retrieved using the `getCookies` method. This method returns all of the cookies found in the request sent by the client.

Go back to Question 12 (p. 2182)

5.4.9.4.3 Answer 11

True.

Go back to Question 11 (p. 2181)

5.4.9.4.4 Answer 10

True.

Go back to Question 10 (p. 2181)

5.4.9.4.5 Answer 9

False. The **Cookie** class represents a cookie that can be used for session management with the HTTP protocol.

Go back to Question 9 (p. 2181)

5.4.9.4.6 Answer 8

True.

Go back to Question 8 (p. 2181)

5.4.9.4.7 Answer 7

True.

Go back to Question 7 (p. 2181)

5.4.9.4.8 Answer 6

True.

Go back to Question 6 (p. 2181)

5.4.9.4.9 Answer 5

False. The **setMaxAge** method can be called to override the default and specify the maximum age of a cookie in seconds. The cookie will expire when the maximum age has been reached.

Go back to Question 5 (p. 2181)

5.4.9.4.10 Answer 4

False. By default, a cookie expires when the browser exits

Go back to Question 4 (p. 2180)

5.4.9.4.11 Answer 3

False.

By default, cookies are sent only to the host that caused them to be saved. Methods can be called to set attributes for each cookie that determine which servers will receive the cookie. For example, the **setDomain** method can be used to specify a domain pattern indicating which servers should receive a cookie.

By default, cookies are sent to the page that set the cookie and to all the pages in that directory or under that directory. This also can be modified by calling the **setPath** method on the cookie.

Go back to Question 3 (p. 2180)

5.4.9.4.12 Answer 2

True.

Go back to Question 2 (p. 2180)

5.4.9.4.13 Answer 1

False. *Cookies* are information that is created by a web application and stored on the client machine by the browser. Under certain conditions, this information is sent to the HTTP server whenever a request is sent from the client to the server.

Go back to Question 1 (p. 2180)

5.4.9.5 Miscellaneous

This section contains a variety of miscellaneous information.

5.4.10.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX. The purpose of this module is to explain session tracking using a servlet and the *session tracking API* .

¹²⁰This content is available online at <<http://cnx.org/content/m48579/1.6/>>.

5.4.10.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.4.10.2.1.1 Figures

- Figure 1 (p. 2187) . Output from access #1.
- Figure 2 (p. 2187) . Output from access #2.
- Figure 3 (p. 2188) . Output from access #3.
- Figure 4 (p. 2189) . Output from access #4.
- Figure 5 (p. 2190) . Output from access #5.
- Figure 6 (p. 2191) . Output from access #6.
- Figure 7 (p. 2192) . Output from access #7.

5.4.10.2.1.2 Listings

- Listing 1 (p. 2194) . Beginning of the doGet method.
- Listing 2 (p. 2194) . Get the session object.
- Listing 3 (p. 2197) . Get an output stream.
- Listing 4 (p. 2198) . A hit counter.
- Listing 5 (p. 2198) . Insert a Date object into the session.
- Listing 6 (p. 2199) . An object of type MyClass.
- Listing 7 (p. 2199) . Display information about the session.
- Listing 8 (p. 2200) . Display information about the objects.
- Listing 9 (p. 2202) . The inner class named MyClass.
- Listing 10 (p. 2204) . The servlet named Java4580a.java.

5.4.10.3 General background information

5.4.10.3.1 Introduction

This is the fourth in a series of modules designed to show you how to implement session tracking using servlets. As mentioned earlier, the purpose of this module is to illustrate session tracking using the *session tracking API* .

Earlier modules have illustrated three different ways to implement session tracking with servlets

- hidden fields
- URL rewriting
- cookies

A higher-level approach to session tracking

The servlet programs in those earlier modules were written at a fairly low level. The *session tracking API* allows you to program at a somewhat higher level. Before you get too excited, however, be aware that this may or may not be the answer to your needs. In some cases, depending on the server involved, you may find that the session tracking API relies exclusively on cookies. If that is the case with your server and if your clients don't allow cookies, then the API may not meet your needs. You may find yourself back at square one – *hidden fields* or *URL rewriting* .

The HttpSession interface

The capability that I have referred to as the *session tracking API* is primarily based on the **HttpSession** interface that I will discuss later. It also includes some other interfaces and classes as well.

5.4.10.3.2 Program output

Figure 1 (p. 2187) through Figure 7 (p. 2192) show the output produced by the servlet named **Java4580a** for each of the first seven times it is accessed by the same browser. You might just want to glance over these Figures now. I will refer back to them and explain their meaning throughout the discussion of the servlet.

Figure 1 - Output from access #1.

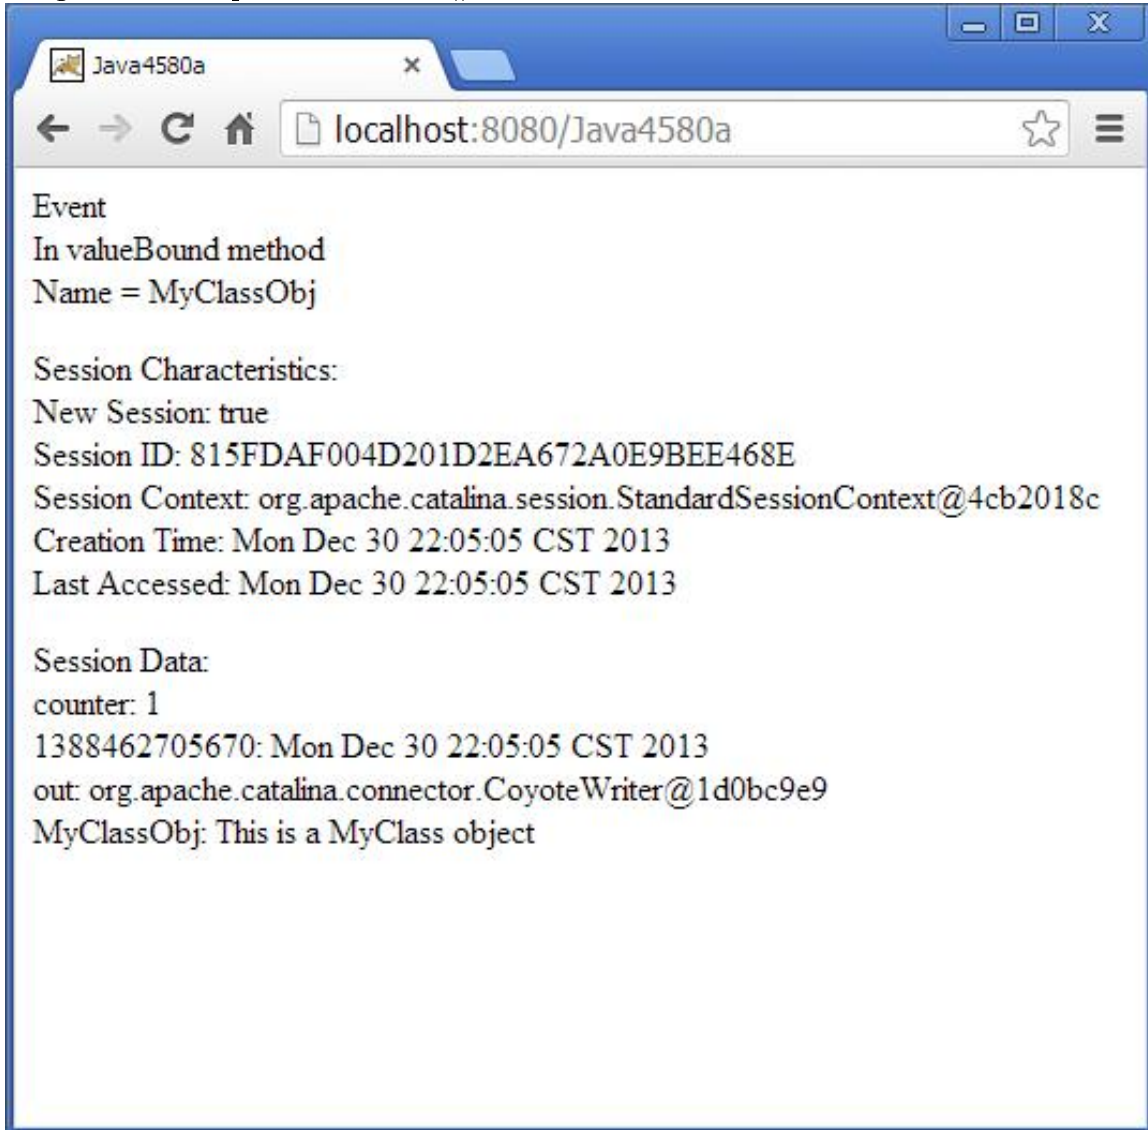

Figure 2 - Output from access #2.

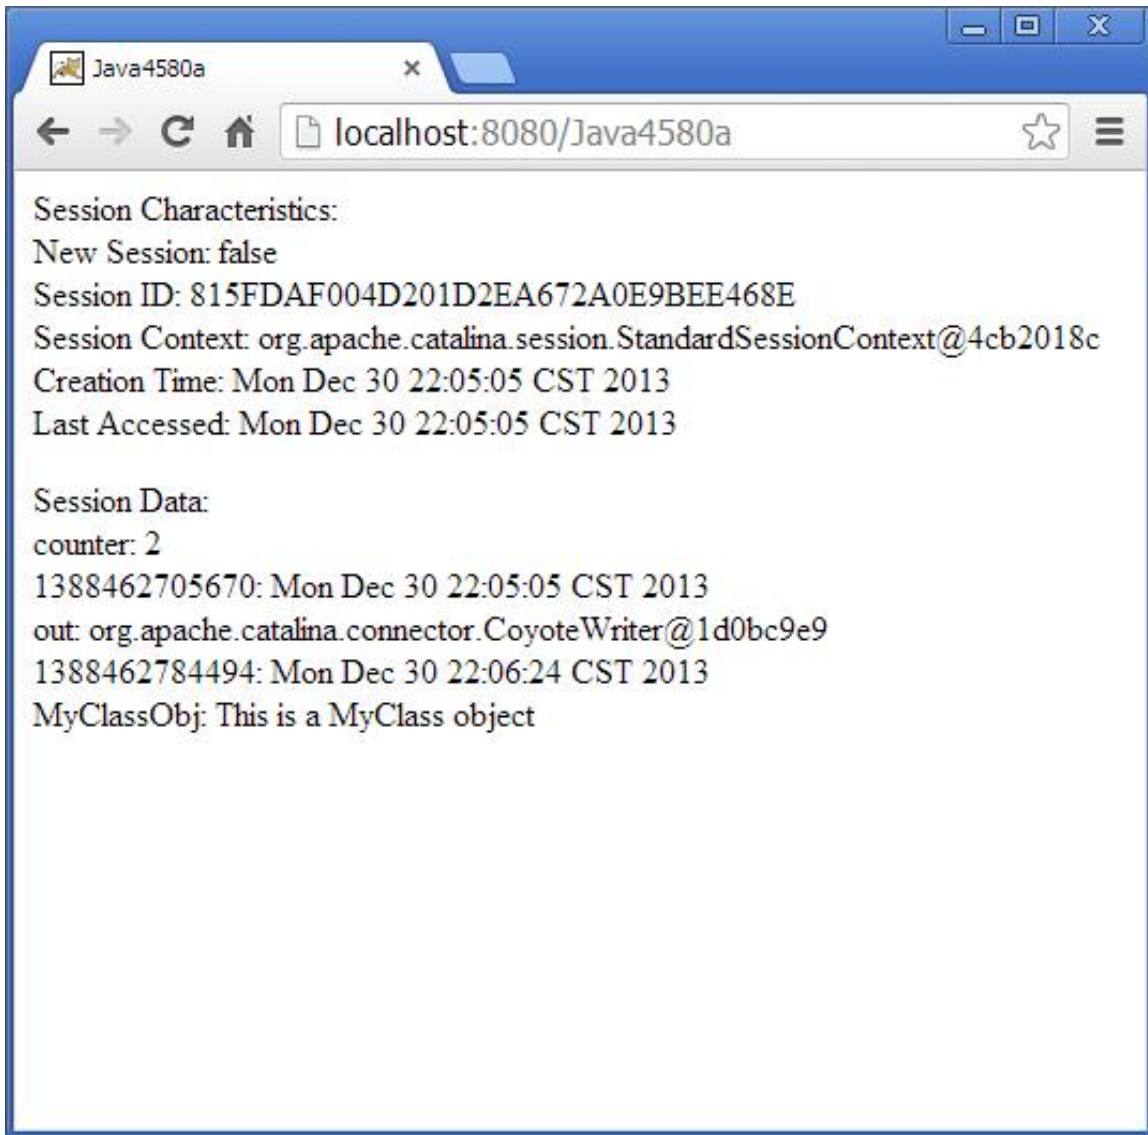

Figure 3 - Output from access #3.

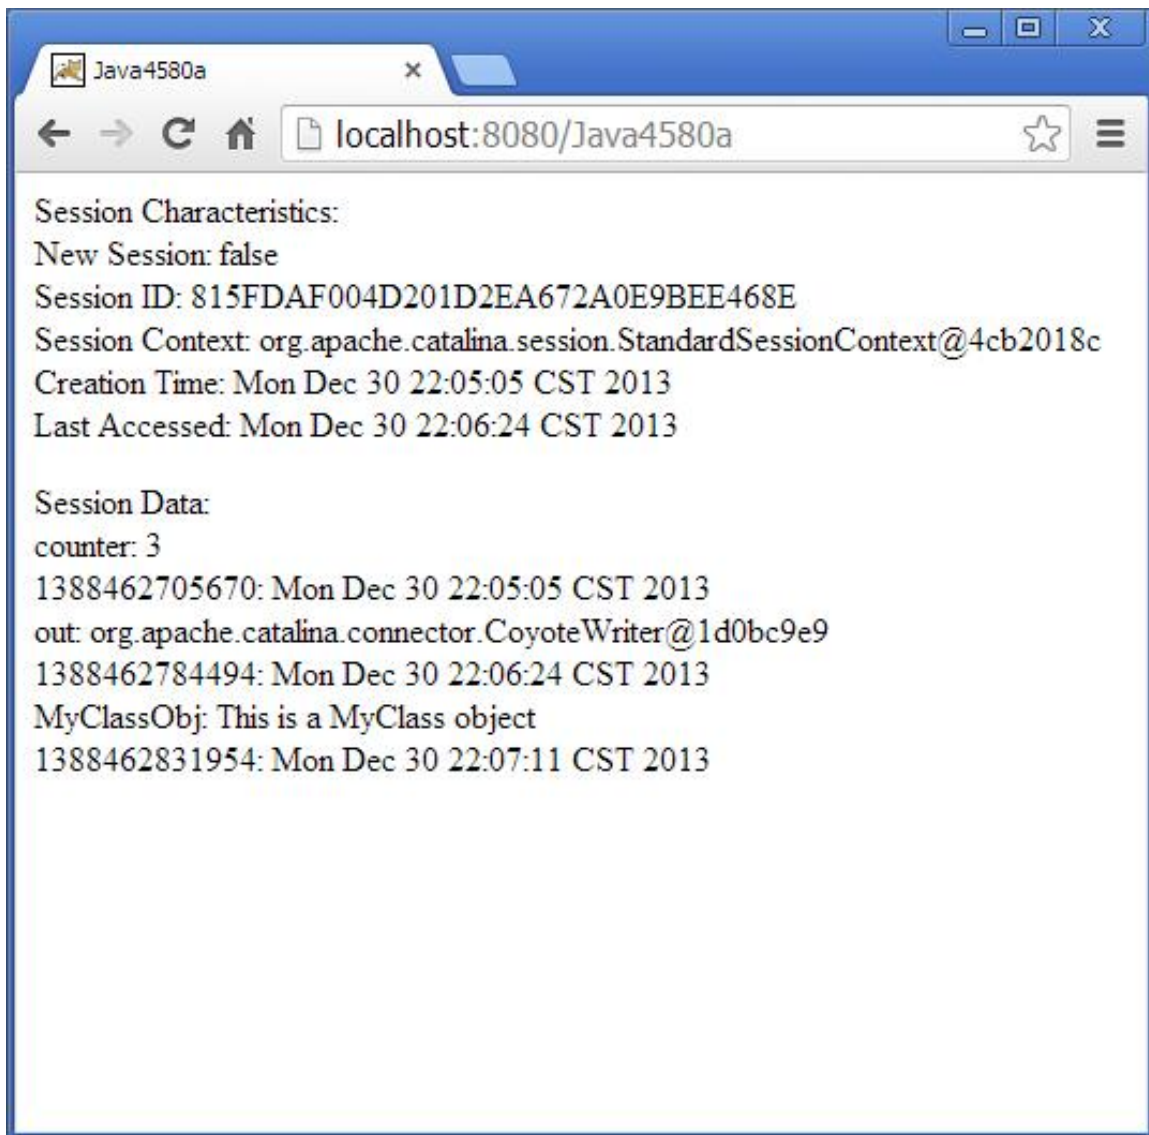

Figure 4 - Output from access #4.

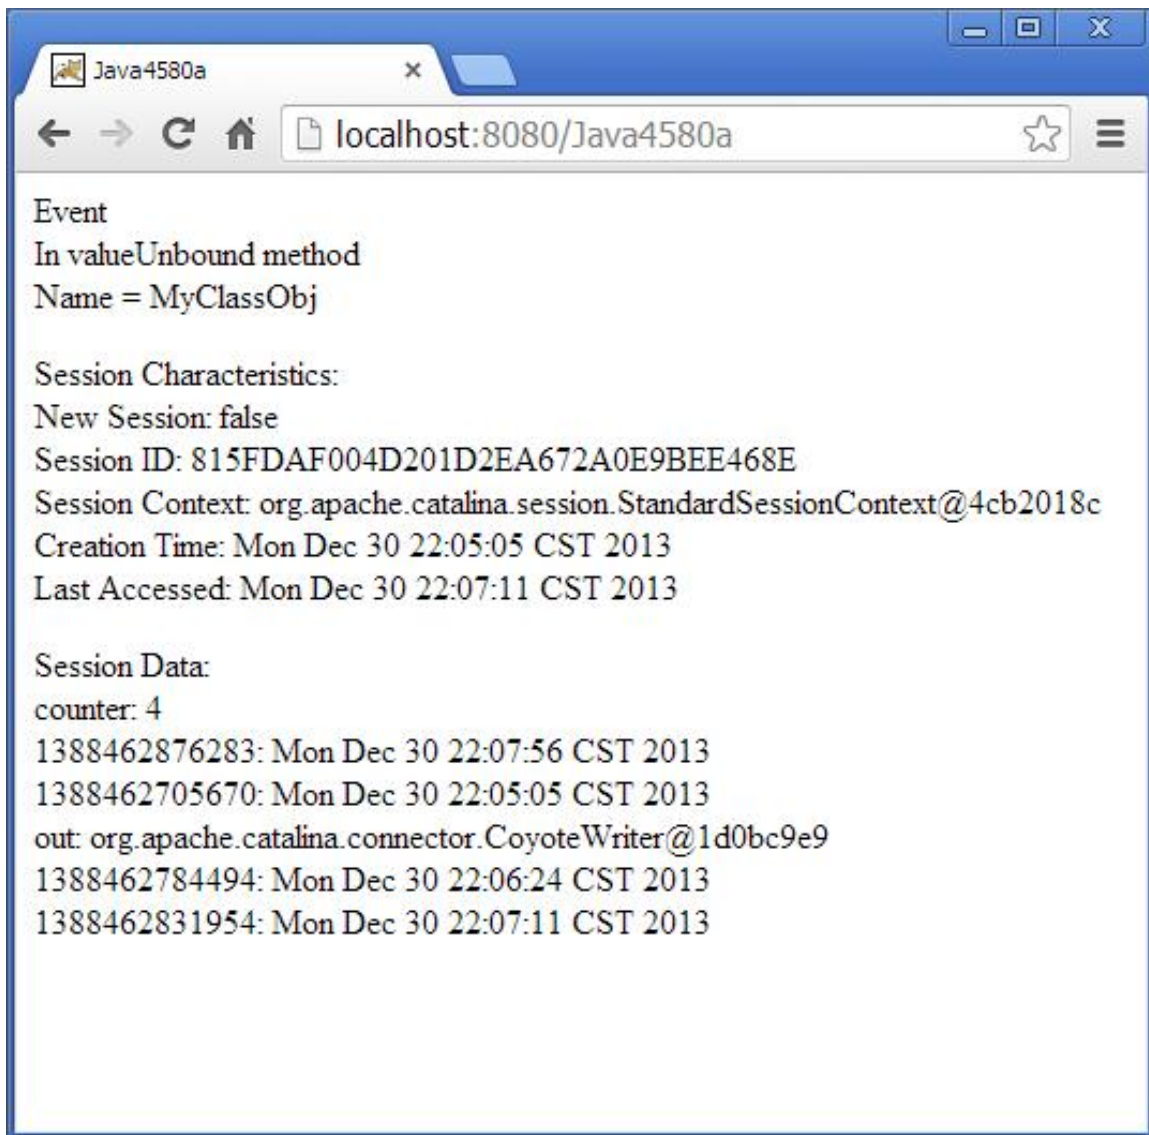

Figure 5 - Output from access #5.

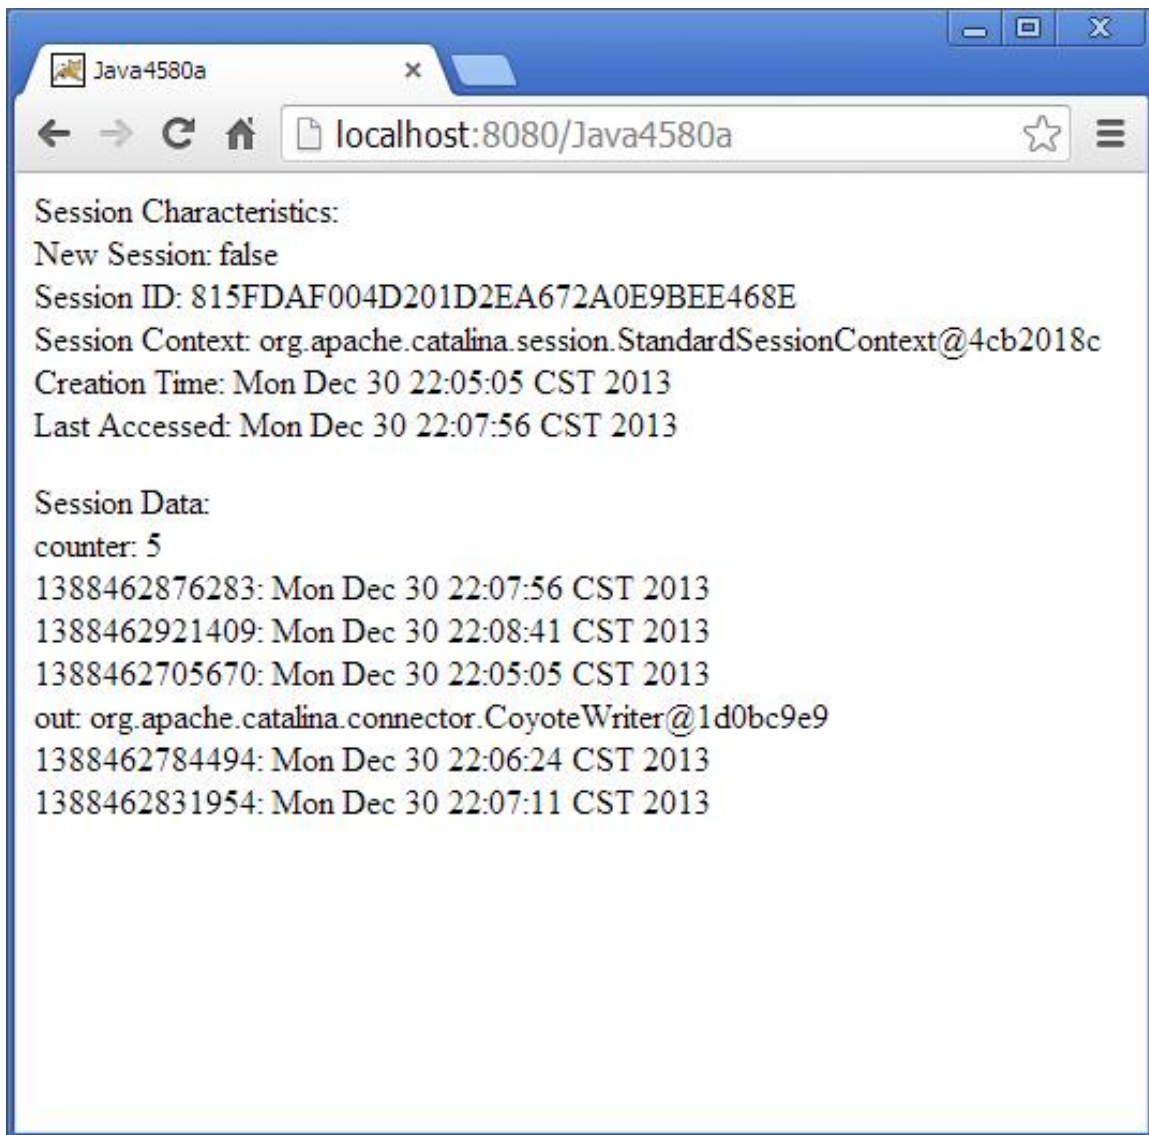

Figure 6 - Output from access #6.

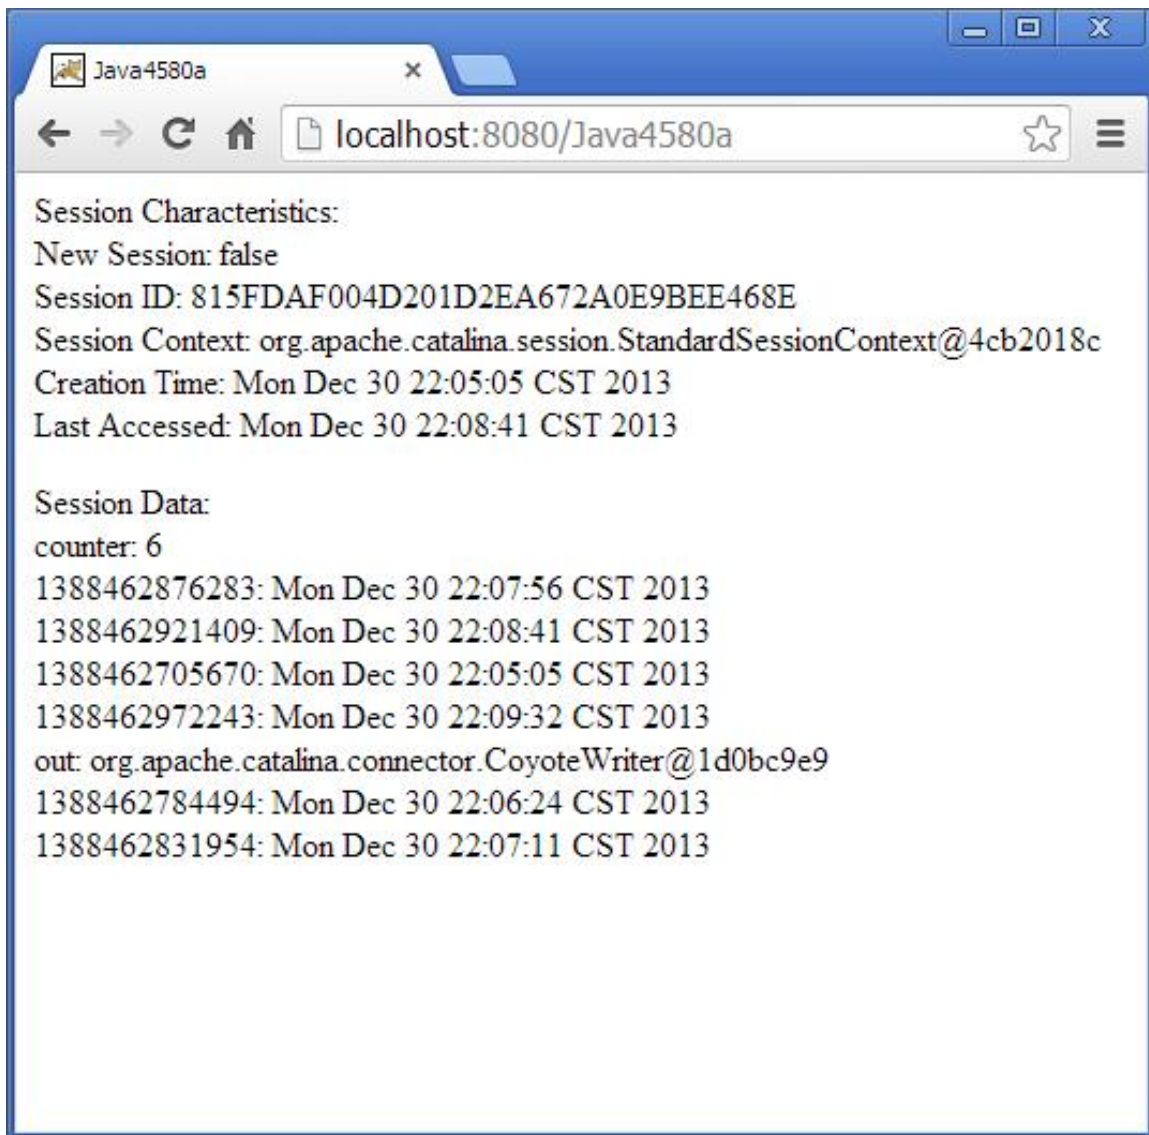

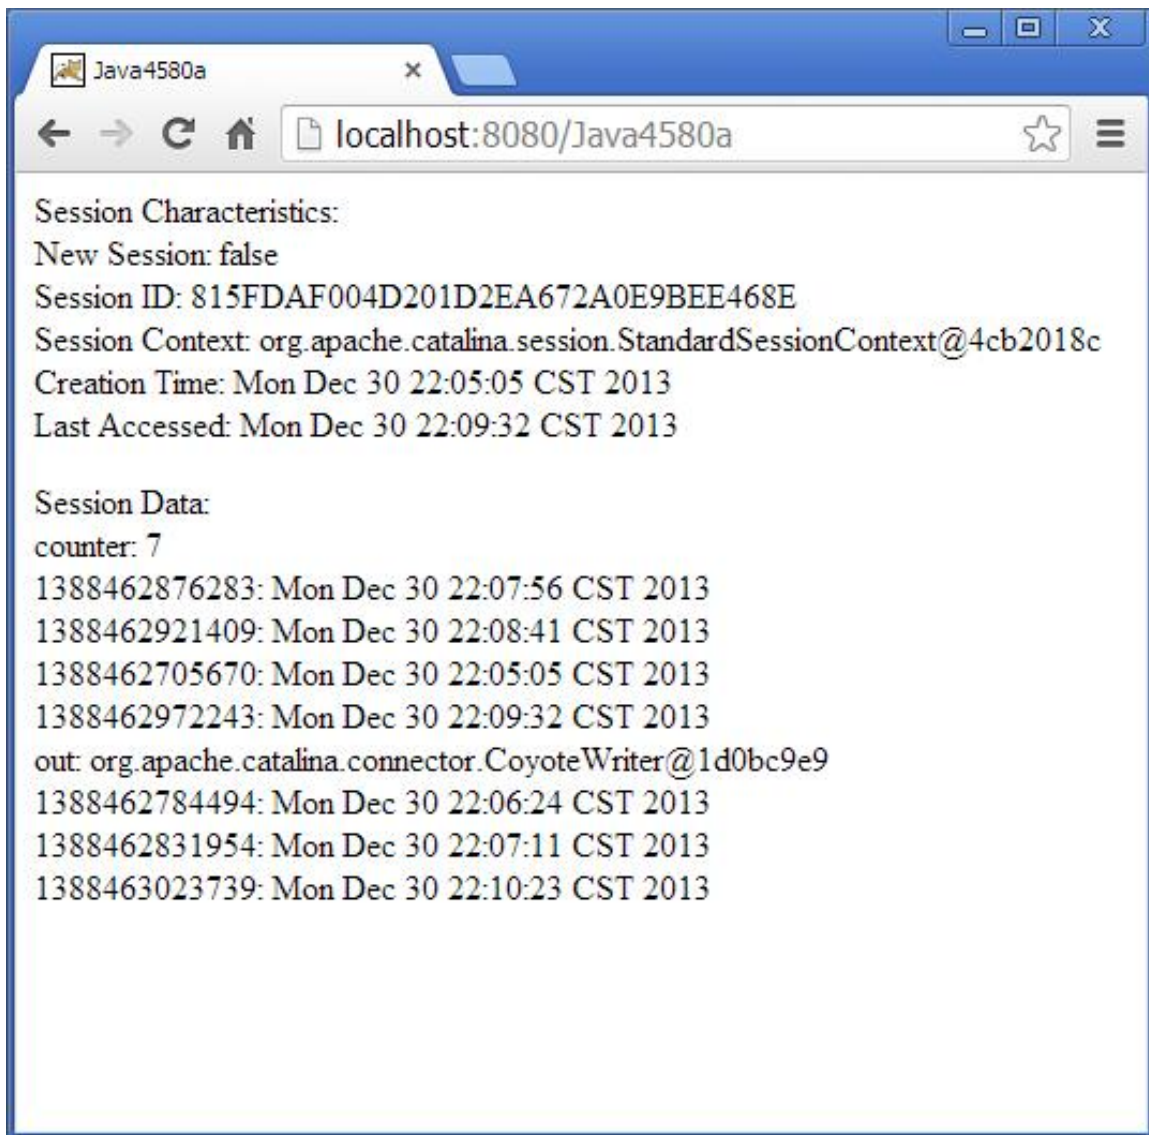

Figure 7 - Output from access #7.

5.4.10.3.3 The HttpSession Interface

I will explain the code in this servlet in fragments. A complete listing of the servlet is provided in Listing 10 (p. 2204).

Beginning of the doGet method

Listing 1 (p. 2194) shows typical code for beginning the definition of a servlet class and for beginning the definition of the `doGet` method. You have seen code like this in earlier modules so I won't discuss it further in this module.

Listing 1 - Beginning of the doGet method.

```

import java.io.*;
import java.util.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class Java4580a extends HttpServlet{

    public void doGet(HttpServletRequest request,
                      HttpServletResponse response)
                      throws ServletException, IOException{

```

Table 5.105**Get the session object**

I will continue the discussion with the code fragment shown in Listing 2 (p. 2194) , where **request** is a reference to the standard object of type **HttpServletRequest** passed to the **doGet** method that begins in Listing 1 (p. 2194) .

Listing 2 - Get the session object.

```

HttpSession session = request.getSession(true);

```

Table 5.106**An object of type HttpSession**

The call to the **getSession** method in Listing 2 (p. 2194) returns a reference to an object of the interface type **HttpSession** . As you can see, the reference is saved in the local variable named **session** .

The **HttpSession** object provides an association (*a session*) between an HTTP client and an HTTP server. This association, or session, persists over multiple connections and/or requests during a given time period. Sessions are used to maintain state and user identity across multiple page requests.

How is the session maintained?

Apparently the manner in which the association between the client and the server (*the session*) is maintained varies from one server to the next. One books states,

"A session can be maintained either by using cookies or by URL rewriting."

Another book states that the minimum requirement for servers is to maintain the session using cookies, and that the server may optionally support URL rewriting as well. There are inferences in other books to the effect that some servers may not support URL rewriting.

The HttpSession object

The **HttpSession** object returned by the code in Listing 2 (p. 2194) behaves as a container for the storage of:

- Information about the session

- Data (*objects*) that persist from one call to the servlet to the next call to the servlet by the same client.

Client ID is transparent

The requirement to maintain the identification of each individual client is transparent to the programmer. That information is encapsulated in the **HttpSession** object and the process that backs it up.

The lifetime of a session

An **HttpSession** object represents an ongoing session with a particular client. The actual lifetime of a session isn't clear in the books that I have read.

The books seems to imply that the session can remain active over long periods of time. However, on my local Tomcat server, the session ends when the browser is terminated. The behavior is similar to that which occurs with the default behavior¹²¹ of cookies that expire when the browser exits.

*(Recall however, the **setMaxAge** method can be called on a cookie to cause it to persist beyond the current active period of the browser. Browsers save long-life cookies from one active period to the next. There may be some way to accomplish that using the session tracking API as well but that is speculation on my part.)*

On my server, the session continues until

- The client exits the browser
- The servlet purposely invalidates the session
- The server invalidates the session due to timeout or other condition

Maintaining session state

All that the programmer has to do to maintain session state is to put objects into the **HttpSession** object, and to get objects from the **HttpSession** object.

The programmer can also get information about the session from the **HttpSession** object as well.

Name::value pairs

Data objects are stored in the **HttpSession** object using a dictionary-like interface. Each object stored in the **HttpSession** object is stored under a **String** name. Data objects are retrieved under the name associated with the object. *(This is another case of using name::value pairs.)*

The fact that the data objects may actually be stored on the client machine (*possibly in cookies*) is transparent to the programmer.

Is the data stored in cookies?

With my local Tomcat server, the fact that the data objects are being stored in cookies on the client machine can be verified by setting the browser preferences to disallow the use of cookies. This results in the counter value that I will explain later never progressing beyond that shown in Figure 1 (p. 2187) . This indicates that the servlet is unable to establish a session when cookies are disabled.

Events

If you instantiate your data objects from classes of your own design, you can process events that are generated whenever the object is put in or removed from the **HttpSession** object. In order to be able to receive events, your classes must implement the **HttpSessionBindingListener** interface.

*(I also believe, but am not certain, that in order for the objects instantiated from your classes to be eligible for being saved in the session object, your classes must implement the **Serializable** interface. This makes it possible to decompose an object into a stream of bytes and to reconstruct those bytes into an object later.)*

Event handlers

When a data object of a class that implements the **HttpSessionBindingListener** interface is put into the **HttpSession** object, the following method is called on the data object:

¹²¹http://cnx.org/content/m48571/latest/#What_are_cookies

valueBound(HttpSessionBindingEvent e)

When a data object of a class that implements the **HttpSessionBindingListener** interface is removed from the **HttpSession** object, the following method is called on the data object:

valueUnbound(HttpSessionBindingEvent e)**No registration is required**

Unlike the typical case in Java programming, no special registration of the event listener is required. Simply implementing the interface on the object is sufficient to cause it to receive events when it is put into or removed from the **HttpSession** object. You can define those two methods to provide whatever behavior may be needed when the events occur.

The isNew method

An implementation of **HttpSession** represents the server's view of the session. The server considers a session to be *new* until the client has joined it. Until the client joins the session, the **isNew** method returns true.

A value of true can indicate one of the following three cases:

- The client does not yet know about the session
- The session has not yet begun
- The client chooses not to join the session.

The third case will occur if the server supports only cookies and the client chooses to reject cookies sent by the server (*the client has disabled cookies on the browser*) .

URL rewriting

According to the some books, the third case will not commonly occur, if the server supports URL rewriting. However, according to one of my books, even if the server supports URL rewriting, that capability is not freely available. The programmer must provide special programming constructs to take advantage of URL rewriting.

In any event, it is the responsibility of the programmer to design the application to account for situations where a client has not joined a session.

5.4.10.4 Discussion and sample code

Now that you have the background information under your belt, let's take a look at a sample program.

The name of the servlet that I will explain in this module is **Java4580a** . As mentioned earlier, I will explain this program in fragments. A complete listing is provided in Listing 10 (p. 2204) .

Beginning of the servlet program

The program begins in the typical manner shown earlier in Listing 1 (p. 2194) . Then the program gets a valid **HttpSession** object for the current request from the client as shown by the call to the **getSession** method in Listing 2 (p. 2194) .

What does Oracle have to say?

Here is some of what Oracle has to say about the **getSession** method, where **create** is the name of the **boolean** parameter passed to the method:

*"Returns the current **HttpSession** associated with this request or, if there is no current session and **create** is true, returns a new session. If **create** is false and the request has no valid **HttpSession** , this method returns null. To make sure the session is properly maintained, you must call this method before the response is committed."*

Apparently the server identifies the first request of the session by the fact that the browser doesn't send a cookie (*or the URL hasn't been rewritten*) , but that is just speculation on my part.

Get an output stream

An output stream is needed in order for the servlet to send content to the client browser. An output stream object is created and saved in the session object, thus making it available for as long as the session is active.

You are already familiar with the first statement in Listing 3 (p. 2197) , so nothing more needs to be said about that statement.

Retrieve the stream object from the session object

Beyond that, the code in Listing 3 (p. 2197) begins by attempting to retrieve an output stream object from the session object.

If the call to the `getValue` method on the session object returns null, this indicates that an output stream has not yet been created and saved in the session object. In that case, an output stream object is created and put into the session object where it will be available on subsequent requests to the servlet.

A reference to the new output stream is also saved in the local variable named `out` so that it will be available during the remainder of the `doGet` method. This is what happens at the beginning of a new session with a specific browser.

Listing 3 - Get an output stream.

```
response.setContentType("text/html");

PrintWriter out = (PrintWriter)session.getValue("out");
if(out == null){
    //First request from this client
    out = response.getWriter();
    session.putValue("out",out);
} //end if

//Create HTML page header
out.println("<html>");
out.println("<head><title>Java4580a</title></head>");
out.println("<body>");
```

Table 5.107

An output stream already exists

If the call to the `getValue` method in Listing 3 (p. 2197) returns an output stream, a reference to the output stream is saved in the local variable named `out` . This is what happens in the second and subsequent calls to the servlet during an ongoing session with a specific browser.

Create the HTML header text

Once the output stream is available, the code in Listing 3 (p. 2197) uses it to create the normal header text on the outgoing HTML page.

A hit counter

Listing 4 (p. 2198) instantiates a hit counter object and stores it in the session object under the name "`counter`". If the session doesn't have a `counter` , one is created and its value is initialized to 1. If the session already has a `counter` , it is incremented by 1. Then the new or incremented `counter` is put in the session, replacing the one that was already there.

Listing 4 - A hit counter.

```

Integer cnt = (Integer)session.getValue("counter");

if(cnt == null) cnt = new Integer(1);
else cnt = new Integer(cnt.intValue() + 1);
session.putValue("counter",cnt);

```

Table 5.108

Note that because an object of the **Integer** class is immutable, the only way to increment the **counter** is to create a new **Integer** object to replace the existing one.

The putValue and getValue methods

Listing 4 (p. 2198) also illustrates the **putValue** and **getValue** methods. These methods are used to store and retrieve objects from the session object. The **putValue()** method requires two parameters:

- an object to be stored
- the **String** name under which the object is to be stored

The **getValue** method requires the **String** name of the object to retrieve.

Insert a Date object into the session

As shown in Listing 5 (p. 2198) , each time the servlet is called, a new **Date** object containing the current date and time is instantiated and stored in the session object.

Listing 5 - Insert a Date object into the session.

```

Date theDate = new Date();
long millis = theDate.getTime();
String strMillis = "" + millis;
session.putValue(strMillis,theDate);

```

Table 5.109

Each **Date** object is stored under a name created by converting the current date and time in milliseconds to a **String** . Thus, the amount of data stored in the session object increases with each call to the servlet.

(Note that if the servlet is called twice by the same client within one millisecond, this naming scheme will fail due to duplicate names being created and put into the session object.)

An object of type MyClass

When the value of the hit counter is 1, an object of type **MyClass** is instantiated and stored in the session object under the name **MyClassObj** . This is shown in Listing 6 (p. 2199) . Note in particular that a reference to the output stream object is passed to the constructor for the **MyClass** object. You will see why later.

Listing 6 - An object of type MyClass.

```

if(cnt.intValue() == 1)
    session.putValue("MyClassObj", new MyClass(out));
if(cnt.intValue() == 4) session.removeValue("MyClassObj");

```

Table 5.110

Also as shown in Listing 6 (p. 2199) , this object is removed from the session object when the value of the hit counter is 4.

An **HttpSessionBindingEvent** event happens when the object is put into the session object and happens again when the object is removed from the session object.

Event handling

The object of type **MyClass** is a listener for events of type **HttpSessionBindingEvent** . Therefore, it receives an event notification when it is put into the session object, and receives another event notification when it is removed from the session object. Information about the two events is displayed on the client screen when the events occur.

The text at the top of Figure 1 (p. 2187) was produced when the **MyClass** object was put into the session. The text at the top of Figure 4 (p. 2189) was produced when the object was removed from the session. More information about that text will be provided later during the discussion of the class named **MyClass** .

Display information about the session

The code in Listing 7 (p. 2199) displays several pieces of information about the session each time the servlet is called. This information is obtained from the session object by calling various methods on the session object. The information is then mixed with standard HTML code and displayed on the client screen as shown in Figure 1 (p. 2187) through Figure 7 (p. 2192) .

Listing 7 - Display information about the session.

```

    out.println("<p>Session Characteristics:<br/>");
out.println("New Session: " + session.isNew()+ "<br/>");
out.println("Session ID: " + session.getId()+ "<br/>");
out.println("Session Context: "
    + session.getSessionContext()+ "<br/>");
out.println("Creation Time: "
    + new Date(session.getCreationTime()) + "<br/>");
out.println("Last Accessed: "
    + new Date(session.getLastAccessedTime()) + "</p>");

```

Table 5.111**Display information about the objects**

The code in Listing 8 (p. 2200) displays information about each of the objects stored in the session object each time the servlet is called. Note that the order of the display of objects doesn't seem to follow any particular pattern.

Listing 8 - Display information about the objects.

```

        out.println("<p>Session Data:<br/>");
String[] names = session.getValueNames();
for(int i = 0; i < names.length; i++){
    out.println(names[i] + ": "
                + session.getValue(names[i]) + "<br/>");
}
}

//Finish off the HTML page
out.println("</p></body></html>");
}

```

Table 5.112

The code in Listing 8 (p. 2200) calls the `getValueNames` method to create a **String** array containing the names of each of the objects currently stored in the session object. A **for** loop then iterates on that array, calling the `getValue` method on each name to get and display each of the objects stored in the session object.

(The code in Listing 8 (p. 2200) also finishes off the web page and signals the end of the `doGet` method.)

The information that is displayed

The following information about the objects is displayed in Figure 1 (p. 2187) through Figure 3 (p. 2188):

- **counter information**
- information about each of the **Date** objects
- information about the output stream object
- information about the object of type **MyClass** .

Beginning with Figure 4 (p. 2189) , the **MyClass** object is no longer contained in the session object when the list is constructed, so only information about the first three items in the above list (p. 2200) is displayed.

Miscellaneous things worthy of note

In Figure 1 (p. 2187) , you see three types of information being displayed:

- Event
- Session Characteristics
- Session Data

The **Event** output resulted from the fact that the object of type **MyClass** was put into the session object. This caused the `valueBound` method to be called.

The **Session Characteristics** show that the creation time and the time last accessed are equal, and the session is a new session.

The **Session Characteristics** also show the **Session ID** which has been automatically created for this session and the **Session Context** , which is peculiar to the Tomcat server being used. Neither of these will change for the duration of the session.

The **Session Data** in Figure 1 (p. 2187) shows information on one counter object, one **Date** object, one output stream object, and one object of type **MyClass** .

Figure 1 (p. 2187) through Figure 7 (p. 2192) all show the same **Session ID** and the same **Session Context** .

(Note that unlike the servlet code in earlier modules, I did not write the code that created the session ID.)

In Figure 2 (p. 2187) and Figure 3 (p. 2188) , you see only two types of information being displayed:

- Session Characteristics
- Session Data

There is no event output in these two Figures because the object of type **MyClass** is neither put into nor removed from the session during these calls to the servlet.

Beginning with Figure 2 (p. 2187) , the **New Session** value shows false. In other words, the session is no longer new.

Beginning with Figure 3 (p. 2188) , the **Last Accessed** time differs from the **Creation Time** .

The entire sequence of Figures show a sequence of seven calls to the servlet. Hence, the value of the counter increases by one in each succeeding Figure. Also, the number of objects in the list increases by one during each of the first three Figures.

Figure 4 (p. 2189) shows the screen output for the fourth call to the servlet. This is the call where the **MyClass** object was removed from the session object. Hence an **Event** occurred showing that the **valueUnbound** method was called.

The **Session Data** consists of one counter object, one output stream object, and four **Date** objects. The **MyClass** object no longer appears in the list because it was removed from the session object before the list was constructed.

Finally, Figure 7 (p. 2192) shows the screen output for the seventh call to the servlet. There is no **Event** output and the **Session Characteristics** are the same as before except for the time last accessed.

The **Session Data** consists of one counter object, one output stream object, and seven **Date** objects.

The inner class named **MyClass**

The code in Listing 9 (p. 2202) defines an inner class named **MyClass** . It could have been implemented as a top-level class but I elected to make it an inner class (*actually a member class*¹²²) .

¹²²<http://cnx.org/content/m44347/latest/?collection=col11441/latest>

Listing 9 - The inner class named MyClass.

```

        class MyClass implements HttpSessionBindingListener,
                                   Serializable{
    PrintWriter localOut;//local copy of output stream to client

    public MyClass(PrintWriter out){//constructor
        //Save a local copy of the output stream to the client.
        localOut = out;
    }//end constructor

    public String toString(){
        return "This is a MyClass object";
    }//end toString()

    //This method is called when the object is put into
    // the session.
    public void valueBound(HttpSessionBindingEvent e){
        localOut.println("<p>Event<br/>");
        localOut.println("In valueBound method<br/>");
        //Returns the name of the object as identified when
        // put into the session
        localOut.println("Name = " +e.getName() + "</p>");
    }//end valueBound()

    //This method is called when the object is removed
    // from the session.
    public void valueUnbound(HttpSessionBindingEvent e){
        localOut.println("<p>Event<br/>");
        localOut.println("In valueUnbound method<br/>");
        localOut.println("Name = " +e.getName() + "</p>");
    }//end valueUnbound()
    }//end inner class named MyClass

} //end class Java4580a

```

Table 5.113**Deploying the servlet**

When this program is compiled, it produces the following two class files:

- Java4580a.class
- Java4580a\$MyClass.class

The second class file results from the compilation of the member class.

I mention this as a reminder that it is necessary to copy both of these class files in order to deploy the servlet onto a web server. Note however that when deploying on my local Tomcat server, only the information about the top level class must be entered into the file named **web.xml** .

A MyClass object

An object of the class named `MyClass` is instantiated and put into the session object during the first call to the servlet when the hit counter equals one. (See Listing 6 (p. 2199) .) The object is removed during the fourth call to the servlet when the hit counter equals four. (Again, see Listing 6 (p. 2199) .)

A listener object

Because the class implements the `HttpSessionBindingListener` interface, an object of the class is a listener for events of type `HttpSessionBindingEvent` . An event of this type occurs when the object is put into the session object. Another event of this type occurs when the object is removed from the session object.

Event handler methods

The method named `valueBound` is called when the object is put into the session object. The method named `valueUnbound` is called when the object is removed from the session object.

No registration necessary

Unlike typical Java event programming, it is not necessary to register the listener on a source. Simply implementing the `HttpSessionBindingListener` interface is sufficient to cause the object to be notified of the events when an object of the class is put into or removed from the session object.

An object of type `HttpSessionBindingEvent`

When an event occurs, the event handler methods named `valueBound` and `valueUnbound` receive a reference to an object of type `HttpSessionBindingEvent` as a parameter.

In this program, the event handlers call the `getName` method on the event objects to display information about the events on the client screen when the events occur. This is shown in Figure 1 (p. 2187) and Figure 4 (p. 2189) . Several other methods are available to be called on the event object including:

- `getName`
- `getSession`
- `getValue`
- `getSource`

An overridden `toString` method

In addition to the two event handler methods, the `MyClass` class also overrides the `toString` method. Note that the string returned by the overridden `toString` method is displayed in Figure 1 (p. 2187) through Figure 3 (p. 2188) to represent the `MyClass` object that is contained in the session object.

Event handler behavior

My objective was to display the name returned by the `getName` method on the browser screen for each event as shown by the third line in Figure 1 (p. 2187) and the third line in Figure 4 (p. 2189) . In order to accomplish this, the code in the event handler methods need access to the output stream object. This was accomplished by

- passing a reference to the output stream object to the `MyClass` constructor
- saving that reference in an instance variable of the `MyClass` object
- using that reference inside the event handler methods to send content to the browser

Standard source-listener event handling

Except for the fact that there is no requirement to register the event listener object on a source, this is straightforward source-listener event handling material that you should already be familiar with.

The code in Listing 9 (p. 2202) also signals the end of the class named `Java4590a` .

5.4.10.5 Run the program

I encourage you to copy the code from Listing 10 (p. 2204) . Compile the code and deploy it on your server. Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

5.4.10.6 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

5.4.10.7 Complete program listing

Listing 10 - The servlet named Java4580a.java.

```
/*File Java4580a.java, Copyright 1999, R.G.Baldwin
Revised 12/30/13
```

This servlet illustrates use of the session tracking API.
A variety of different aspects of session tracking using
the API are illustrated.

```
*****/
import java.io.*;
import java.util.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class Java4580a extends HttpServlet{

    public void doGet(HttpServletRequest request,
                      HttpServletResponse response)
                      throws ServletException, IOException{

        //Get the session associated with this request,
        HttpSession session = request.getSession(true);
```

```
response.setContentType("text/html");

//Get the output stream from the session object.
// If this is the first call to servlet, create an output
// stream and save it in the session object.
PrintWriter out = (PrintWriter)session.getValue("out");
if(out == null){
    //First request from this client
    out = response.getWriter();
    session.putValue("out",out);
} //end if

//Create HTML page header
out.println("<html>");
out.println("<head><title>Java4580a</title></head>");
out.println("<body>");

//Create a hit counter for this servlet
Integer cnt = (Integer)session.getValue("counter");
if(cnt == null) cnt = new Integer(1);
else cnt = new Integer(cnt.intValue() + 1);
session.putValue("counter",cnt);

//Add a new Date object each time the servlet is called
Date theDate = new Date();
long millis = theDate.getTime();
String strMillis = "" + millis;
session.putValue(strMillis,theDate);

//When the hit counter is 1, instantiate a new object of
// type MyClass and put it in the session. Pass
// a reference to the output stream to the constructor.
//Remove the object from the session when the value
// of the hit counter is 4.
if(cnt.intValue() == 1)
    session.putValue("MyClassObj", new MyClass(out));
if(cnt.intValue() == 4) session.removeValue("MyClassObj");

//Display information about the session.
out.println("<p>Session Characteristics:<br/>");
out.println("New Session: " + session.isNew()+ "<br/>");
out.println("Session ID: " + session.getId()+ "<br/>");
out.println("Session Context: "
    + session.getSessionContext()+ "<br/>");
out.println("Creation Time: "
    + new Date(session.getCreationTime()) + "<br/>");
out.println("Last Accessed: "
    + new Date(session.getLastAccessedTime()) + "</p>");

//Display information about all of the objects currently in
```

```

// the session. Note that the session now contains a
// PrintWriter object that was not in the session in the
// original version of the servlet named Java4580a.
out.println("<p>Session Data:<br/>");
String[] names = session.getValueNames();
for(int i = 0; i < names.length; i++){
    out.println(names[i] + ": "
                + session.getValue(names[i]) + "<br/>");
}
}

//Finish off the HTML page
out.println("</p></body></html>");
}

5.4.11 Java4580r-Review¹²³

5.4.11.1 Table of Contents

- Preface (p. 2207)
- Questions (p. 2207)
 - 1 (p. 2207) , 2 (p. 2207) , 3 (p. 2207) , 4 (p. 2208)
- Answers (p. 2209)
- Miscellaneous (p. 2210)

5.4.11.2 Preface

This module is one in a collection of modules designed for teaching **INEW 2338 Advanced Java (Web)** at Austin Community College in Austin, TX.

This module contains review questions and answers keyed to the module titled Java4580: Session Tracking using the Session Tracking API ¹²⁴ in the Servlets sub-collection.

Once you study that module, you should be able to answer the review questions in this module.

The questions and the answers in this module are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

5.4.11.3 Questions

5.4.11.3.1 Question 1

True or False?

The *session tracking API* allows you to program at a somewhat higher level than when programming for

- hidden fields
- URL rewriting
- cookies

Go to answer 1 (p. 2209)

5.4.11.3.2 Question 2

True or False?

In some cases, depending on the server involved, the *session tracking API* may rely exclusively on cookies "under the hood."

Go to answer 2 (p. 2209)

5.4.11.3.3 Question 3

True or False?

The *session tracking API* is primarily based on the **JavaHttpSession** interface. It also includes some other interfaces and classes as well.

Go to answer 3 (p. 2209)

¹²³This content is available online at <<http://cnx.org/content/m49586/1.2/>>.

¹²⁴<http://cnx.org/content/m48579/latest/?collection=col11441/latest>

5.4.11.3.4 Question 4

True or False?

A call to the `getSession` method of the incoming request object returns a reference to an object of the interface type `HttpSession` .

The `HttpSession` object provides an association (*a session*) between an HTTP client and an HTTP server. This association, or session, persists over multiple connections and/or requests during a given time period. Sessions can be used to maintain state and user identity across multiple page requests.

Go to answer 4 (p. 2209)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.4.11.4 Answers

5.4.11.4.1 Answer 4

True.

Go back to Question 4 (p. 2208)

5.4.11.4.2 Answer 3

False. The *session tracking API* is primarily based on the **HttpSession** interface. It also includes some other interfaces and classes as well.

Go back to Question 3 (p. 2207)

5.4.11.4.3 Answer 2

True.

Go back to Question 2 (p. 2207)

5.4.11.4.4 Answer 1

True.

Go back to Question 1 (p. 2207)

5.4.11.5 Miscellaneous

This section contains a variety of miscellaneous information.

5.5 JSON

5.5.1 Json0195: Preface to JSON¹²⁵

Revised: Thu Jun 02 18:43:34 CDT 2016

This page is included in the following Books:

- *INEW2338 - Advanced Java Programming* ¹²⁶
- *Object-Oriented Programming (OOP) with Java* ¹²⁷

5.5.1.1 Table of contents

- Table of contents (p. 2210)
- Servlets, search engines, or JSON (p. 2211)
- Miscellaneous (p. 2211)

¹²⁵This content is available online at <<http://cnx.org/content/m61773/1.1/>>.

¹²⁶<http://cnx.org/contents/yWyT-uhM>

¹²⁷http://cnx.org/contents/-2RmHF_s_

5.5.1.2 Servlets, search engines, or JSON

As explained in the page titled Java4510: Preface to INEW 2338 ¹²⁸, only one of the topics *Search Engines*, *Servlets*, or *JSON* is covered in the course in any particular semester. However, all three are important. The course material in the Blackboard course management program indicates which topic is covered in the current semester.

Students are encouraged to study all three topics for their own educational purposes in order to enhance their prospects of landing a job as a Java programmer.

5.5.1.3 Miscellaneous

This section contains a variety of miscellaneous information.

5.5.2.2 Preface

5.5.2.2.1 What is JSON?

The online document titled *Introducing JSON*¹³³ begins as follows:

"JSON (JavaScript Object Notation) is a lightweight data-interchange format. It is easy for humans to read and write. It is easy for machines to parse and generate. It is based on a subset of the JavaScript Programming Language, Standard ECMA-262 3rd Edition - December 1999. JSON is a text format that is completely language independent but uses conventions that are familiar to programmers of the C-family of languages, including C, C++, C#, Java, JavaScript, Perl, Python, and many others. These properties make JSON an ideal data-interchange language."

Similarly, the online document titled *Java API for JSON Processing: An Introduction to JSON*¹³⁴ begins as follows:

JSON (JavaScript Object Notation) is a lightweight, text-based, language-independent data exchange format that is easy for humans and machines to read and write. JSON can represent two structured types: objects and arrays. An object is an unordered collection of zero or more name/value pairs. An array is an ordered sequence of zero or more values. The values can be strings, numbers, booleans, null, and these two structured types.

It is important to note that even though JSON is based on JavaScript syntax, JSON is not JavaScript nor is it any other programming language. In fact, it is not a programming language at all. As stated above, JSON is simply *"a lightweight, text-based, language-independent data exchange format"* – nothing more and nothing less.

Figure 1 (p. 2212) shows a JSON text string containing name/value pairs as well as nested arrays.

Figure 1. Example JSON text.

¹³³<http://www.json.org/>

¹³⁴<http://www.oracle.com/technetwork/articles/java/json-1973242.html>

```

{
  "game":
  [
    { "cards":
      [
        "2-club", "3-heart", "4-diamond", "5-spade"
      ],
      "name": "Tom"
    },
    { "cards":
      [
        "4-heart", "5-heart", "6-club", "7-diamond"
      ],
      "name": "Joe"
    }
  ]
}

```

(This JSON text will be used in a Java program in a future module.)

5.5.2.2.2 Why should you care about JSON?

This book is being written and published under the following assumptions:

- You are interested in Java programming.
- You are interested in web development involving Java programming.
- At some point in the future, you may become interested in Big Data ¹³⁵.
- At some point in the future, you may become interested in NoSQL ¹³⁶ databases such as MongoDB ¹³⁷ and Couchbase ¹³⁸.

As stated in the InfoWorld ¹³⁹ article of August 25, 2014:

"Web developers love JSON (JavaScript Object Notation). Like XML, it's a human-readable format for transmitting data, except it's a whole lot easier to work with than XML. ... Several NoSQL databases – including the wildly successful MongoDB ¹⁴⁰ and Couchbase ¹⁴¹ – store data in JSON documents natively."

According to How JSON and Big Data Will Shape the Internet of Things ¹⁴², the author writes:

"To answer the question of why JSON would be the most widely used format for the Internet of Things, one only need look at the rapid development of Raspberry Pi, which started a little over two-and-a-half years ago, and has gained massive traction worldwide. This credit-card sized microcomputer is extensible, and a recent project called RaZberry has turned it into a device capable of controlling your home automation through - you guessed it - a JSON interface. With

¹³⁵https://en.wikipedia.org/wiki/Big_data

¹³⁶<https://en.wikipedia.org/wiki/NoSQL>

¹³⁷<https://www.mongodb.com/>

¹³⁸<http://www.couchbase.com/>

¹³⁹<http://www.infoworld.com/article/2608805/database/big-databases-jump-on-the-json-bandwagon.html>

¹⁴⁰<http://www.mongodb.com/>

¹⁴¹<http://www.couchbase.com/>

¹⁴²<http://news.sys-con.com/node/2881856>

future development of the Internet of Things, the proliferation of JSON as the preferred data delivery mechanism will only increase.

Even more interesting is how this data can be fed into a Big Data cluster to perform predictive modeling and analytics. Just over a year ago, Google BigQuery ¹⁴³ added support for JSON ¹⁴⁴ and explicitly mentions how sensor data and its attributes can be measured as a consequence. With time, it is only inevitable that developers in other Big Data ecosystems will use JSON when setting up their clusters to perform analytics from the various source data from the Internet of Things."

According to the aforementioned Google BigQuery ¹⁴⁵ support for JSON ¹⁴⁶ article:

"JSON is the data format of the web. JSON is used to power most modern websites, is a native format for many NoSQL databases hosting top web applications, and provides the primary data format in many REST APIs. Google BigQuery, our cloud service for ad-hoc analytics on big data, has now added support for JSON and the nested/repeated structure inherent in the data format."

I could go on providing similar quotations, but the bottom line is that if you anticipate your Java programming career taking you into the world of Big Data ¹⁴⁷ or into The Internet of Things ¹⁴⁸ at some point in the future, you probably need to learn how to write Java programs that parse, generate, transform, and query JSON.

5.5.2.2.3 Not a book about JSON

This book is not intended to teach you about JSON. There are numerous tutorials on the web that you can access for that purpose (see *Online references* (p. 2216)). This book is intended to teach you how to use the json-simple ¹⁴⁹ Java library, (*which is one of several available libraries*), to parse, generate, transform, and query JSON.

The page at <http://www.json.org/> ¹⁵⁰ lists more than two dozen Java libraries that have been created for processing JSON data. After conducting an informal review of web pages that discuss the various libraries, I decided to concentrate on the json-simple ¹⁵¹ library in this book. For example, here is the conclusion from the article titled A Review of 5 Java JSON Libraries ¹⁵² :

"If you are looking for a simple lightweight Java library that reads and writes JSON, and supports Streams, JSON.simple is probably a good match. It does what it says on the box in 12 classes, and works on legacy (1.4) JREs. "

This conclusion is similar to conclusions that I found on several other websites. However, you should not take my selection of json-simple ¹⁵³ for this book as a recommendation for the json-simple ¹⁵⁴ library as compared to other libraries that are available. Once you have a basic understanding of how to process JSON using Java and the json-simple ¹⁵⁵ library, you should conduct your own review to identify the library that best suits your needs.

5.5.2.2.4 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view Figure 1 (p. 2212) while you are reading about it.

5.5.2.3 Background information

JSON is an acronym for **JavaScript Object Notation** . Don't be fooled by the name however. Although JSON is based on JavaScript object syntax, it is not JavaScript nor is it any programming language. As stated earlier, JSON is simply a *lightweight, text-based, language-independent data interchange format* – nothing more and nothing less.

5.5.2.3.1 A lightweight text-based data interchange format

Similar to XML, JSON is a general purpose data interchange format that is supported by Java, PHP, JavaScript, and other programming languages. JSON is a standard that describes how ordered lists and unordered maps, strings, boolean values, and numbers can be represented as text in a string.

Similar to but less complex than XML, JSON provides a way to pass structured information between different computing environments using the same or different languages.

5.5.2.3.2 Typical operation

Typically a data construct, (*such as an object for example*) , in one programming environment will be transformed into a JSON string. That string will be transported to another programming environment where it will be transformed into a data construct, (*such as a hash table for example*) , that is suitable for use in that programming environment

5.5.2.3.3 A real-world analogy

Consider the following analogous situation. A young family has a large playscape for their children in their back yard. They need to move to another house across town. In order to save money, they rent a small truck and do the entire move themselves.

5.5.2.3.3.1 A playscape object

The playscape can be thought of as an object with certain properties such as **swing** and **slide** .

It is too large to fit into the truck so the adults disassemble it into a well-organized package of boards, chains, bolts, nuts, etc. They are very careful to label each part and to create some drawings showing the organization of the parts for use later.

5.5.2.3.3.2 No longer an object

In that disassembled state, it can no longer be thought of as an object with properties of **swing** and **slide** . Instead, it is simply a well-organized and documented package of parts. The package of parts is analogous to a JSON string. The playscape object has been transformed into a well-organized package of parts.

5.5.2.3.3.3 Reassemble the parts

After the parts are transported to the new location, they are reassembled into an object with properties of **swing** and **slide** .

This is what we do with JSON. We disassemble an object (*or other data construct*) into a JSON string: a well-organized package of parts. Later on, and possibly in an entirely different programming environment, we reassemble the parts into a data construct suitable for use in the new programming environment.

5.5.2.3.3.4 Streamlined procedures

Java, JavaScript, PHP, and other programming languages provide streamlined procedures for transforming a data construct into a JSON string and for transforming a JSON string into a suitable data construct. As an example, the `toJSONString` method can be used to transform a Java object of type `JSONObject` into a JSON string. The `parse` method of the Java `JSONValue` class can be used to transform a JSON string into a `JSONObject` object. Other methods or functions are available to accomplish the same purposes in other languages such as JavaScript ¹⁵⁶.

5.5.2.4 Online references

There are many good online JSON references. Here are a few:

5.5.3.3 Questions

5.5.3.3.1 Question 1 .

True or False? JSON is an acronym for "Java Object Names."

Go to answer 1 (p. 2222)

5.5.3.3.2 Question 2

True or False? JSON is based on a subset of the JavaScript Programming Language.

Go to answer 2 (p. 2222)

5.5.3.3.3 Question 3

True or False? JSON is a text format that is language independent but uses conventions that are familiar to programmers of the C-family of languages including C, C++, C#, Java, JavaScript, Perl, Python, Visual Basic, and many others.

Go to answer 3 (p. 2222)

5.5.3.3.4 Question 4

True or False? JSON is part of the JavaScript programming language.

Go to answer 4 (p. 2222)

5.5.3.3.5 Question 5

True or False? JSON can represent three structured types: objects, arrays, and conditionals.

Go to answer 5 (p. 2222)

5.5.3.3.6 Question 6

True or False? Figure 1 (p. 2222) shows a JSON text string containing name/value pairs as well as nested arrays.

Go to answer 6 (p. 2221)

5.5.3.3.7 Question 7

True or False? JSON is important in the implementation of Big Data ¹⁷⁰ NoSQL ¹⁷¹ databases such as MongoDB ¹⁷² and Couchbase ¹⁷³ .

Go to answer 7 (p. 2221)

5.5.3.3.8 Question 8

True or False? This book is intended to teach you about JSON.

Go to answer 8 (p. 2221)

¹⁷⁰https://en.wikipedia.org/wiki/Big_data

¹⁷¹<https://en.wikipedia.org/wiki/NoSQL>

¹⁷²<https://www.mongodb.com/>

¹⁷³<http://www.couchbase.com/>

5.5.3.4 Figure index

- Figure 1 (p. 2222)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.5.3.5 Answers

5.5.3.5.1 Answer 8

False. This book is not intended to teach you about JSON. There are numerous tutorials on the web that you can access for that purpose. This book is intended to teach you how to use the `json-simple`¹⁷⁴ Java library, (*which is one of several available libraries*), to parse, generate, transform, and query JSON.

Go back to Question 8 (p. 2219)

5.5.3.5.2 Answer 7

True. According to the InfoWorld¹⁷⁵ article of August 25, 2014, "Several NoSQL databases – including the wildly successful MongoDB¹⁷⁶ and Couchbase¹⁷⁷ – store data in JSON documents natively."

Go back to Question 7 (p. 2219)

5.5.3.5.3 Answer 6

True.

Go back to Question 6 (p. 2219)

¹⁷⁴<https://code.google.com/archive/p/json-simple/>

¹⁷⁵<http://www.infoworld.com/article/2608805/database/big-databases-jump-on-the-json-bandwagon.html>

¹⁷⁶<https://www.mongodb.com/>

¹⁷⁷<http://www.couchbase.com/>

5.5.3.5.4 Answer 5

False. According to the online document titled Java API for JSON Processing: An Introduction to JSON¹⁷⁸, "JSON can represent two structured types: objects and arrays. An object is an unordered collection of zero or more name/value pairs. An array is an ordered sequence of zero or more values. The values can be strings, numbers, booleans, null, and these two structured types."

Go back to Question 5 (p. 2219)

5.5.3.5.5 Answer 4

False. It is important to note that even though JSON is based on JavaScript syntax, JSON is not JavaScript nor is it any other programming language. In fact, it is not a programming language at all. JSON is simply *"a lightweight, text-based, language-independent data exchange format"* – nothing more and nothing less.

Go back to Question 4 (p. 2219)

5.5.3.5.6 Answer 3

False. Visual Basic is not based on the C-family of languages. Visual Basic is based on the BASIC programming language that came into existence¹⁷⁹ in 1964. The C programming language came into existence¹⁸⁰ independently in 1972.

Go back to Question 3 (p. 2219)

5.5.3.5.7 Answer 2

True.

Go back to Question 2 (p. 2219)

5.5.3.5.8 Answer 1

False. According to the online document titled Introducing JSON¹⁸¹, "JSON (JavaScript Object Notation) is a ...".

Go back to Question 1 (p. 2219)

5.5.3.6 Figures

This section contains Figures that may be referred to by one or more questions or answers. These Figures may also be helpful as reference material for answering the questions.

Figure 1.

¹⁸⁵http://cnx.org/contents/-2RmHFs_

5.5.4.1 Table of contents

- Table of contents (p. 2224)
- Preface (p. 2224)
 - Viewing tip (p. 2224)
 - * Figures (p. 2224)
 - * Listings (p. 2224)
- The json-simple library (p. 2224)
 - Download the library (p. 2224)
 - Library documentation (p. 2225)
 - Install the library (p. 2225)
 - Test your installation (p. 2225)
- Miscellaneous (p. 2226)

5.5.4.2 Preface

This is a page from the book titled **The json-simple Java Library** . The book explains how to use the **json-simple** Java library to generate, transform, and query JSON text. This page explains how to get started using the library.

5.5.4.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.5.4.2.1.1 Figures

- Figure 1 (p. 2226) . Output from test program.

5.5.4.2.1.2 Listings

- Listing 1 (p. 2225) . Java test program.
- Listing 2 (p. 2225) . Sample batch file.

5.5.4.3 The json-simple library

5.5.4.3.1 Download the library

As of May 2016, the library can be downloaded in a jar file named `json-simple-1.1.1.jar`¹⁸⁶ . The name of the jar file may be expected to change over time as new versions are released.

¹⁸⁶<https://code.google.com/archive/p/json-simple/downloads>

5.5.4.3.2 Library documentation

Also as of May 2016, a file named `json_simple-1.1-all.zip`, which contains source code for the library, can be downloaded from that same page. See the contents of that zip file for a copy of the license covering the material in the library.

I used the source code from that file to create a documentation package for version 1.1, which you can download here ¹⁸⁷. Download and extract the contents of the file named `docs.zip` into an empty folder and open the file named `index.html` in your browser to view the documentation in standard `javadoc` format.

5.5.4.3.3 Install the library

To use the library, you need to download the latest version of the jar file, store it somewhere on your system, and put it on your classpath. The instructions on this page apply to Windows 7. If you are using some other operating system, you will need to adjust the instructions to make them compatible with your operating system.

5.5.4.3.4 Test your installation

Create a Java source code file named `Code` containing the code shown in Listing 1 (p. 2225) and store it in a folder somewhere on your system.

Listing 1 . Java test program.

```

/*****
Tested with Java 8, Windows 7, and
json-simple-1.1.1.jar
*****/
import org.json.simple.ItemList;

class Code{
    public static void main(String[] args){
        System.out.println("ItemList: " + new ItemList().
                           getClass().getSuperclass());
    }//end main
}//end class code

```

Assuming that you have downloaded the jar file and stored it in a folder named `json-simple` in the root directory of your C drive, create a batch file containing the commands shown in Listing 2 (p. 2225) and store the batch file in the same folder as the source code file named `Code`.

Listing 2 . Sample batch file.

```

echo off
rem Sets the classpath, compiles, and runs Code.java.

del *.class

javac -cp .;C:\json-simple\json-simple-1.1.1.jar Code.java

```

¹⁸⁷<http://cnx.org/content/m61718/latest/docs.zip>

```
java -cp .;C:\json-simple\json-simple-1.1.1.jar Code
pause
```

Double-click the batch file. Assuming that you have a compatible version of the Java Development Kit installed on your system, your test program should be compiled and executed, producing the output shown in Figure 1 (p. 2226) on your computer screen.

Figure 1. Output from test program.

```
ItemList: class java.lang.Object
Press any key to continue . . .
```

By way of explanation, the code in Listing 1 (p. 2225) instantiates a new object of the class named **ItemList** from the JSON library. Then it gets and displays the superclass of that class, which is the class named **Object** . In other words, the JSON library class named **ItemList** extends the standard class named **Object** .

If you were able to produce the output shown in Figure 1 (p. 2226) , you are ready to start generating, transforming, and querying JSON text using Java and the **json-simple** Java library.

5.5.4.4 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.5.5.4 Answers

5.5.5.4.1 Answer 2

False. The **json-simple** library class named **ItemList** extends the standard Java class named **Object**.

Go back to Question 2 (p. 2227)

5.5.5.4.2 Answer 1

False. To use the library, you need to download the latest version of the jar file, store it somewhere on your system, and put it on your operating system's **classpath** environment variable.

Go back to Question 1 (p. 2227)

5.5.5.5 Miscellaneous

This section contains a variety of miscellaneous information.

5.5.6 Json0210: Structure of the json-simple Java Library¹⁹³

Revised: Thu Jun 02 19:23:22 CDT 2016

This page is included in the following Books:

- *The json-simple Java Library* ¹⁹⁴ .
- *INEW2338 - Advanced Java Programming* ¹⁹⁵
- *Object-Oriented Programming (OOP) with Java* ¹⁹⁶

5.5.6.1 Table of contents

- Table of contents (p. 2230)
- Preface (p. 2230)
 - Viewing tip (p. 2231)
 - * Figures (p. 2231)
 - * Listings (p. 2231)
- General background information (p. 2231)
- Discussion and sample code (p. 2231)
- What you can expect (p. 2232)
- Run the program (p. 2232)
- Complete program listing (p. 2232)
- Miscellaneous (p. 2233)

5.5.6.2 Preface

This is a page from the book titled **The json-simple Java Library** . The book explains how to use the **json-simple** Java library to generate, transform, and query JSON text. This page explains the inheritance structure of the **json-simple** Java library and how it fits into the standard Java library.

¹⁹³This content is available online at <<http://cnx.org/content/m61723/1.3/>>.

¹⁹⁴<http://cnx.org/contents/5sRB9gpG>

¹⁹⁵<http://cnx.org/contents/yWyT-uhM>

¹⁹⁶http://cnx.org/contents/-2RmHFs_

5.5.6.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.5.6.2.1.1 Figures

- Figure 1 (p. 2231) . Inheritance hierarchy.

5.5.6.2.1.2 Listings

- Listing 1 (p. 2232) . Program named Code.java.

5.5.6.3 General background information

The earlier page titled *Json0205: Getting Started*¹⁹⁷ provided a download link for a standard **javadoc** documentation package for version 1.1 of the **json-simple** Java library. That documentation package shows that the library contains the following packages:

- `org.json.simple`
- `org.json.simple.parser`

Those packages contain the following classes and interfaces with the interfaces **shown in Italics** :

- *ContainerFactory*
- *ContentHandler*
- `ItemList`
- `JSONArray`
- *JSONAware*
- `JSONObject`
- `JSONParser`
- *JSONStreamAware*
- `JSONValue`
- `ParseException`
- `Ytoken`

The jar file also contains a class named **Yylex** in the **org.json.simple.parser** package that did not show up in the documentation. It didn't show up in the documentation because it is *package-private* and therefore not intended for our direct use. It is used internally by code in the class named **JSONParser** .

5.5.6.4 Discussion and sample code

Listing 1 (p. 2232) provides the code for a Java program that establishes the position in the class hierarchy of each of the classes (p. 2231) in the **json-simple** library by displaying the superclass of each of those classes. Figure 1 (p. 2231) shows the screen output produced by this program.

Figure 1. Inheritance hierarchy.

¹⁹⁷<http://cnx.org/contents/5sRB9gpG:9MswajcY>

```

ItemList: class java.lang.Object
JSONArray: class java.util.ArrayList
JSONObject: class java.util.HashMap
JSONParser: class java.lang.Object
JSONValue: class java.lang.Object
ParseException: class java.lang.Exception
Yytoken: class java.lang.Object

```

The class named **ParseException** extends the standard class named **Exception** as you might expect.

Four of the classes extend the class named **Object** , which is not particularly surprising. New classes extend the **Object** class by default unless they are defined to purposely extend some other class.

The most important thing shown in Figure 1 (p. 2231) is that the **JSONArray** class extends the standard **ArrayList** class and the **JSONObject** class extends the standard **HashMap** class. These standard classes are part of the *Java Collections Framework* .

This illustrates one of the most important features of the **json-simple** library. The library maximizes the use of standard classes from the *Java Collections Framework* . Once you have a reference to an object of the **JSONArray** class or an object of the **JSONObject** class, you have access to all of the polymorphic features provided by that framework. You also have access to the methods defined by those two classes and the classes defined by their superclasses. Therefore, if you are already skilled at programming within the collections framework, it is a small step to add JSON programming to your skill set.

5.5.6.5 What you can expect

This book will explain how to use the following classes:

- JSONObject
- JSONValue
- JSONParser
- JSONArray
- ParseException

An investigation into the use of the other classes and interfaces will be left as *"an exercise for the student"* .

5.5.6.6 Run the program

I encourage you to copy the code from Listing 1 (p. 2232) . Execute the code and confirm that you get the same results as those shown in Figure 1 (p. 2231) . Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

5.5.6.7 Complete program listing

Listing 1 (p. 2232) provides the source code for the program named **Code.java** .

Listing 1 . Program named Code.java.

```

/*****
Copyright 2016, R.G.Baldwin
Establishes the position of each of the json-simple classes in the
class hierarchy by getting and displaying the superclass of each

```

```
class.
```

Produces the following output:

```
ItemList: class java.lang.Object
JSONArray: class java.util.ArrayList
JSONObject: class java.util.HashMap
JSONParser: class java.lang.Object
JSONValue: class java.lang.Object
ParseException: class java.lang.Exception
Yytoken: class java.lang.Object
```

Tested with Java 8, Windows 7, and json-simple-1.1.1.jar

```
*****/
import org.json.simple.JSONObject;
import org.json.simple.JSONArray;
import org.json.simple.JSONValue;
import org.json.simple.ItemList;
import org.json.simple.JSONAware;
import org.json.simple.parser.JSONParser;
import org.json.simple.parser.ParseException;
import org.json.simple.parser.Yytoken;
```

```
class Code{
    public static void main(String[] args){

        System.out.println("ItemList: " +
            new ItemList().getClass().getSuperclass());
        System.out.println("JSONArray: " +
            new JSONArray().getClass().getSuperclass());
        System.out.println("JSONObject: " +
            new JSONObject().getClass().getSuperclass());
        System.out.println("JSONParser: " +
            new JSONParser().getClass().getSuperclass());
        System.out.println("JSONValue: " +
            new JSONValue().getClass().getSuperclass());
        System.out.println("ParseException: " +
            new ParseException(ParseException.ERROR_UNEXPECTED_CHAR).
                getClass().getSuperclass());
        System.out.println("Yytoken: " +
            new Yytoken(Yytoken.TYPE_COLON,";").
                getClass().getSuperclass());

        }//end main
    }//end class code
```

5.5.6.8 Miscellaneous

5.5.7.3 Questions

5.5.7.3.1 Question 1 .

True or False? Version 1.1 of the **json-simple** Java library contains the following packages:

- `org.json.simple`
- `org.json.simple.parser`

Go to answer 1 (p. 2239)

5.5.7.3.2 Question 2

True or False? Version 1.1 of the **json-simple** Java library contains the public classes shown below

- `ItemList`
- `JSONArray`
- `JSONObject`
- `JSONParser`
- `JSONValue`
- `ParseException`
- `Object`
- `Ytoken`

Go to answer 2 (p. 2239)

5.5.7.3.3 Question 3

True or False? Version 1.1 of the **json-simple** Java library contains a class named **Yylex** in the **org.json.simple.parser** package that is declared to be *package-private* .

Go to answer 3 (p. 2239)

5.5.7.3.4 Question 4

True or False? Despite its name, the **JSONArray** class is not really an array. Instead, it is a **List** .

Go to answer 4 (p. 2239)

5.5.7.3.5 Question 5

True or False? Objects of the **JSONArray** class contain *unordered* data.

Go to answer 5 (p. 2239)

5.5.7.3.6 Question 6

True or False? Other than the **JSONObject** class and the **JSONArray** class, all of the classes in version 1.1 of the **json-simple** Java library extend the **Object** class.

Go to answer 6 (p. 2239)

5.5.7.3.7 Question 7

True or False? The **JSONObject** class extends the standard Java **TreeSet** class.

Go to answer 7 (p. 2239)

5.5.7.3.8 Question 8

True or False? An object of the `JSONObject` class maps *keys* or *names* to *values* .
Go to answer 8 (p. 2238)

5.5.7.3.9 Question 9

True or False? An object of the `JSONObject` class can contain duplicate keys but cannot contain duplicate values.
Go to answer 9 (p. 2238)

5.5.7.3.10 Question 10

True or False? An object of the `JSONObject` class is an unordered collection.
Go to answer 10 (p. 2238)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.5.7.4 Answers

5.5.7.4.1 Answer 10

True. An object of the **JSONObject** class extends the **HashMap** class and implements the **Map** interface. According to the Oracle documentation, *"The order of a map is defined as the order in which the iterators on the map's collection views return their elements. Some map implementations, like the **TreeMap** class, make specific guarantees as to their order; others, like the **HashMap** class, do not."*

Go back to Question 10 (p. 2237)

5.5.7.4.2 Answer 9

False. The **JSONObject** class implements the **Map** interface. According to the Oracle documentation, *"A map cannot contain duplicate keys; each key can map to at most one value."*

Go back to Question 9 (p. 2237)

5.5.7.4.3 Answer 8

True. JSON documentation often speaks of *name/value* pairs. However, the **JSONObject** class extends the standard Java **HashMap** class, which implements the **Map** interface. According to the Oracle Java documentation, an object that implements the **Map** interface is *"An object that maps keys to values."* Therefore, it is probably acceptable to use the terms *name/value* and *key/value* interchangeably.

Go back to Question 8 (p. 2237)

5.5.7.4.4 Answer 7

False. The **JSONObject** class extends the standard Java **HashMap** class.

Go back to Question 7 (p. 2236)

5.5.7.4.5 Answer 6

True.

Go back to Question 6 (p. 2236)

5.5.7.4.6 Answer 5

False. Because the **JSONArray** class extends the **ArrayList** class, which implements the **List** interface, it is *"An ordered collection (also known as a sequence). The user of this interface has precise control over where in the list each element is inserted. The user can access elements by their integer index (position in the list), and search for elements in the list."*

Go back to Question 5 (p. 2236)

5.5.7.4.7 Answer 4

True. The **JSONArray** class extends the standard **ArrayList** class, which implements the **List** interface.

Go back to Question 4 (p. 2236)

5.5.7.4.8 Answer 3

True.

Go back to Question 3 (p. 2236)

5.5.7.4.9 Answer 2

False. Version 1.1 of the **json-simple** Java library does not contain a class named **Object** .

Go back to Question 2 (p. 2236)

5.5.7.4.10 Answer 1

True.

Go back to Question 1 (p. 2236)

5.5.7.5 Miscellaneous

This section contains a variety of miscellaneous information.

5.5.8 Json0215: Encoding JSON Strings²⁰³

Revised: Thu Jun 02 19:24:40 CDT 2016

This page is included in the following Books:

- *The json-simple Java Library* ²⁰⁴ .
- *INEW2338 - Advanced Java Programming* ²⁰⁵
- *Object-Oriented Programming (OOP) with Java* ²⁰⁶

5.5.8.1 Table of contents

- Table of contents (p. 2240)
- Preface (p. 2240)
 - Viewing tip (p. 2241)
 - * Figures (p. 2241)
 - * Listings (p. 2241)
- General background information (p. 2241)
- Discussion and sample code (p. 2241)
 - Create ArrayList containers (p. 2241)
 - Create and populate a JSONObject object (p. 2242)
 - Create and populate two more JSONObject objects (p. 2242)
 - Encode the data into JSON strings (p. 2243)
 - Display the JSON strings (p. 2243)
 - The end of the program (p. 2244)
- Run the program (p. 2244)
- Complete program listing (p. 2244)
- Miscellaneous (p. 2245)

5.5.8.2 Preface

This is a page from the book titled **The json-simple Java Library** . The book explains how to use the **json-simple** Java library to generate, transform, and query JSON text. This page explains how to use the **JSONObject** class to encode key/value pairs into JSON strings.

²⁰³This content is available online at <<http://cnx.org/content/m61724/1.4/>>.

²⁰⁴<http://cnx.org/contents/5sRB9gpG>

²⁰⁵<http://cnx.org/contents/yWyT-uhM>

²⁰⁶http://cnx.org/contents/-2RmHFs_

5.5.8.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.5.8.2.1.1 Figures

- Figure 1 (p. 2243) . The screen output.

5.5.8.2.1.2 Listings

- Listing 1 (p. 2241) . Create ArrayList containers.
- Listing 2 (p. 2242) . Create and populate a JSONObject object.
- Listing 3 (p. 2242) . Create and populate two more JSONObject objects.
- Listing 4 (p. 2243) . Encode the data into JSON strings.
- Listing 5 (p. 2243) . Display the JSON strings.
- Listing 6 (p. 2244) . The program named Code.java.

5.5.8.3 General background information

As you learned in the earlier page titled *Json0210: Structure of the json-simple Java Library* ²⁰⁷, the class named **JSONObject** extends the standard Java class named **HashMap**. Therefore, once you have an object of the class named **JSONObject**, you can call any of the methods defined in or inherited into the **JSONObject** class on that object.

In the sample program that follows, we will use the **put** method that is inherited from the **HashMap** class to populate the object with key/value pairs. We will use the **toJSONString** method that is defined in the **JSONObject** class to transform the populated object into a JSON string.

5.5.8.4 Discussion and sample code

The program named **Code** (see *Listing 6 (p. 2244)*) constructs three **JSONObject** objects, populates the objects with key/value pairs, and saves the **JSONObject** objects in an **ArrayList** object. (Actually it saves references to the **JSONObject** objects in the **ArrayList** object.)

Then it transforms each **JSONObject** object into a JSON string. At this point, the JSON strings could be written to an output stream and transferred to a different programming environment. However, to keep the program simple, the program simply saves the JSON strings in a second **ArrayList** object for later display.

Then the program displays the JSON strings for comparison with the code that populated the **JSONObject** objects in the first place.

5.5.8.4.1 Create ArrayList containers

A complete listing of the program named **Code** is provided in Listing 6 (p. 2244) near the end of the page. I will discuss and explain the code in fragments. The first fragment is shown in Listing 1 (p. 2241).

Listing 1 . Create ArrayList containers.

```
import org.json.simple.JSONObject;
import java.util.ArrayList;
import java.util.Iterator;
```

²⁰⁷http://cnx.org/contents/5sRB9gpG:_u3ZKIdD

```

class Code {

    public static void main(String[] args){
        //Create a container for several JSON objects.
        ArrayList <JSONObject> listA = new ArrayList<JSONObject>();
        //Create a container for several JSON strings
        ArrayList <String> listB = new ArrayList<String>();
    }
}

```

The code in Listing 1 (p. 2241) instantiates two objects of the class named **ArrayList** to serve as containers for the **JSONObject** objects and the JSON strings. This is plain vanilla Java code. There is nothing new here.

5.5.8.4.2 Create and populate a JSONObject object

Listing 2 (p. 2242) creates and populates the first **JSONObject** object with key/value pairs. The keys are "name", "age", and "student" respectively. The value types are **String** , **int** , and **boolean** respectively.

Listing 2 . Create and populate a JSONObject object.

```

listA.add(new JSONObject());

listA.get(0).put("name", "Joe");
listA.get(0).put("age", 21);
listA.get(0).put("student", true);

```

The code in Listing 2 (p. 2242) begins by instantiating a new object of the **JSONObject** class and adding its reference into the first element (*0*) of the **ArrayList** object. Then it calls the **get** method on the **ArrayList** object three times in succession to gain access to the **JSONObject** . Each time it gains access to the **JSONObject** object, it calls the **put** method inherited from the **HashMap** class to store a key/value pair in the **JSONObject** object.

Note that the data stored in the **JSONObject** object is an unordered collection. As you will see later, the order in which the key/value pairs are extracted from the object using an iterator is unrelated to the order in which the key/value pairs are stored in the object.

5.5.8.4.3 Create and populate two more JSONObject objects

Listing 3 (p. 2242) repeats the process two more times to create, populate, and save two more **JSONObject** objects. Note that one of these objects is populated in a different order than is the case in Listing 2 (p. 2242) .

Listing 3 . Create and populate two more JSONObject objects.

```

//Create and populate the second JSONObject.
listA.add(new JSONObject());
listA.get(1).put("student", false);
listA.get(1).put("name", "Sue");

```

```
listA.get(1).put("age",32);

//Create and populate the third JSONObject
listA.add(new JSONObject());
listA.get(2).put("name","Tom");
listA.get(2).put("age",19);
listA.get(2).put("student",true);
```

5.5.8.4.4 Encode the data into JSON strings

Listing 4 (p. 2243) uses an **Iterator** to gain access to each populated **JSONObject** object. Each time it gains access to an object, it calls the **toJSONString** method that is defined in the **JSONObject** class to transform the object into a JSON string.

At this point, the program could write the JSON strings into an output stream for transfer to some other programming environment. However as mentioned earlier, to keep the program simple, the program saves the JSON strings as elements in a second **ArrayList** object.

Listing 4 . Encode the data into JSON strings.

```
Iterator<JSONObject> iteratorA = listA.iterator();
while (iteratorA.hasNext()){
    listB.add(iteratorA.next().toJSONString());
} //end while loop
```

5.5.8.4.5 Display the JSON strings

Listing 5 (p. 2243) uses an **Iterator** to access and display each of the JSON strings that are stored in the **ArrayList** object.

Listing 5 . Display the JSON strings.

```
Iterator<String> iteratorB = listB.iterator();
while (iteratorB.hasNext()){
    System.out.println(iteratorB.next());
} //end while loop

} //end main
} //end class Code
```

The screen output is shown in Figure 1 (p. 2243) .

Figure 1. The screen output.

```
{"student":true,"name":"Joe","age":21}
{"student":false,"name":"Sue","age":32}
{"student":true,"name":"Tom","age":19}
```

The format for each line of text that you see in Figure 1 (p. 2243) is the format that you would expect for a JSON string that doesn't include array data. (See *Introducing JSON*²⁰⁸ for more details regarding format.)

Briefly, each key is separated from its value by a colon (:). Each key/value pair is separated from its neighbors by a comma (,). The JSON string begins with a left brace ({) and ends with a right brace (}). Keys are surrounded by double quotation characters. Values may or may not be separated by double quotation characters, depending on their type. Some characters inside of values, such as double quotation characters and backslash characters must be escaped with a backslash character (\") and \\ but that is not shown by this program.

Note that the display order for the key/value pairs shown in Figure 1 (p. 2243) does not match the order in which the objects were populated in Listing 2 (p. 2242) and Listing 3 (p. 2242). A HashMap does not impose an ordering on its contents and does not guarantee that the ordering will remain constant over time.

5.5.8.4.6 The end of the program

Listing 5 (p. 2243) also signals the end of the `main` method and the end of the program.

5.5.8.5 Run the program

I encourage you to copy the code from Listing 6 (p. 2244). Execute the code and confirm that you get the same results as those shown in Figure 1 (p. 2243). Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

5.5.8.6 Complete program listing

A complete listing of the program named `Code.java` is provided in Listing 6 (p. 2244).

Listing 6. The program named `Code.java`.

```

/*****

5.5.9 Json0215R: Review²⁰⁹

Revised: Sat Jun 04 12:48:39 CDT 2016

This page is included in the following Books:

- *The json-simple Java Library* ²¹⁰ .
- *INEW2338 - Advanced Java Programming* ²¹¹
- *Object-Oriented Programming (OOP) with Java* ²¹²

5.5.9.1 Table of Contents

- Table of Contents (p. 2247)
- Preface (p. 2247)
- Questions (p. 2247)
 - Question 1 (p. 2247)
 - Question 2 (p. 2248)
 - Question 3 (p. 2248)
- Figure index (p. 2248)
- Listing index (p. 2248)
- Answers (p. 2249)
 - Answer 3 (p. 2249)
 - Answer 2 (p. 2249)
 - Answer 1 (p. 2249)
- Figures (p. 2249)
- Listings (p. 2250)
- Miscellaneous (p. 2251)

5.5.9.2 Preface

This is a page from the book titled **The json-simple Java Library** . The book explains how to use the **json-simple** Java library to generate, transform, and query JSON text. This page provides review questions and answers for the page titled **Json0215: Encoding JSON Strings** ²¹³ . Once you study that page, you should be able to answer the review questions in this page.

The questions and the answers in this page are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

The figures and listings (*if any*) are grouped together. It is recommend that when a question or an answer refers to a figure or a listing, that you open it in a new window to make it easy to view it while reading the question or the answer.

5.5.9.3 Questions

5.5.9.3.1 Question 1 .

True or False? Once you have an object of the class named **JSONObject** , you can call any of the methods defined in the **HashMap** class on that object.

Go to answer 1 (p. 2249)

²⁰⁹This content is available online at <<http://cnx.org/content/m61779/1.1/>>.

²¹⁰<http://cnx.org/contents/5sRB9gpG>

²¹¹<http://cnx.org/contents/yWyT-uhM>

²¹²<http://cnx.org/contents/-2RmHFs>

²¹³<http://cnx.org/contents/5sRB9gpG:16t-k2Np>

5.5.9.3.2 Question 2

True or False? The code shown in Listing 1 (p. 2250) produced the screen output shown in Figure 1 (p. 2250) .

Go to answer 2 (p. 2249)

5.5.9.3.3 Question 3

True or False? The code shown in Listing 3 (p. 2251) produced the screen output shown in Figure 3 (p. 2250) .

Go to answer 3 (p. 2249)

5.5.9.4 Figure index

- Figure 1 (p. 2250)
- Figure 2 (p. 2250)
- Figure 3 (p. 2250)

5.5.9.5 Listing index

- Listing 1 (p. 2250)
- Listing 2 (p. 2250)
- Listing 3 (p. 2251)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.5.9.6 Answers

5.5.9.6.1 Answer 3

True. The code in Listing 3 (p. 2251) uses the `get` method inherited from the `HashMap` class to get and display the values associated with the keys "name", "age", and "student".

Go back to Question 3 (p. 2248)

5.5.9.6.2 Answer 2

False. The code in Listing 1 (p. 2250) produced the output with the compiler error message shown in Figure 2 (p. 2250). The output shown in in Figure 1 (p. 2250) was produced by the code shown in Listing 2 (p. 2250). Note the call to the `toJSONString` method of the `JSONObject` class to extract the information from the `JSONObject` object and encode it into a JSON string.

Go back to Question 2 (p. 2248)

5.5.9.6.3 Answer 1

True. The class named `JSONObject` extends the standard Java class named `HashMap`. Therefore, the `JSONObject` class inherits all of the methods defined in the `HashMap` class.

Go back to Question 1 (p. 2247)

5.5.9.7 Figures

This section contains Figures that may be referred to by one or more questions or answers.

Figure 1

```
{"student":true,"name":"Joe","age":21}
```

Figure 2

```
Code01.java:20: error: no suitable method found for get(no arguments)
    String jsonString = jsonObject.get();
```

Figure 3

```
Joe
21
true
```

5.5.9.8 Listings

This section contains Listings that may be referred to by one or more questions or answers.

Listing 1

```
import org.json.simple.JSONObject;

class Code01 {

    public static void main(String[] args){

        JSONObject jsonObject= new JSONObject();
        jsonObject.put("name","Joe");
        jsonObject.put("age",21);
        jsonObject.put("student",true);

        String jsonString = jsonObject.get();
        System.out.println(jsonString);

    }//end main
} //end class Code01
```

Listing 2

```
import org.json.simple.JSONObject;

class Code02 {
```

```
public static void main(String[] args){

    JSONObject jsonObject= new JSONObject();
    jsonObject.put("name","Joe");
    jsonObject.put("age",21);
    jsonObject.put("student",true);

    String jsonString = jsonObject.toJSONString();
    System.out.println(jsonString);

} //end main
} //end class Code02
```

Listing 3

```
import org.json.simple.JSONObject;

class Code03 {

    public static void main(String[] args){

        JSONObject jsonObject= new JSONObject();
        jsonObject.put("name","Joe");
        jsonObject.put("age",21);
        jsonObject.put("student",true);

        System.out.println(jsonObject.get("name"));
        System.out.println(jsonObject.get("age"));
        System.out.println(jsonObject.get("student"));

    } //end main
} //end class Code03
```

5.5.9.9 Miscellaneous

This section contains a variety of miscellaneous information.

 - The end of the program (p. 2256)
- Run the program (p. 2257)
- Complete program listing (p. 2257)
- Miscellaneous (p. 2259)

5.5.10.2 Preface

This is a page from the book titled **The json-simple Java Library** . The book explains how to use the **json-simple** Java library to generate, transform, and query JSON text. This page explains how to decode JSON strings using the parse methods of the **JSONValue** and **JSONParser** classes.

²¹⁴This content is available online at <<http://cnx.org/content/m61725/1.3/>>.

²¹⁵<http://cnx.org/contents/5sRB9gpG>

²¹⁶<http://cnx.org/contents/yWyT-uhM>

²¹⁷http://cnx.org/contents/-2RmHFs_

5.5.10.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.5.10.2.1.1 Figures

- Figure 1 (p. 2255) . Program output.

5.5.10.2.1.2 Listings

- Listing 1 (p. 2254) . Decode and display using the `JSONValue` class.
- Listing 2 (p. 2254) . The method named `decodeC`.
- Listing 3 (p. 2255) . The display method.
- Listing 4 (p. 2255) . Decode and display using the `JSONParser` class.
- Listing 5 (p. 2256) . The method named `decodeD`.
- Listing 6 (p. 2257) . The program named `Code.java`.

5.5.10.3 General background information

As mentioned in the Preface (p. 2252) , this page deals with the classes named `JSONValue` and `JSONParser` . Each of these classes extends the `Object` class and provides various methods for processing JSON data. The page also exposes you to the class named `ParseException` .

All of the methods in the `JSONValue` class are **static** methods. Methods in this class are available to deal with JSON input data in both the string format and the `JSONObject` format.

None of the methods in the `JSONParser` class are static methods. In general the methods in this class are designed to deal only with input data in the string format.

Both classes provide several overloaded **parse** methods that can be used to parse input JSON text from different sources into the `JSONObject` format.

The sample program that follows will use the **parse** method from both classes to parse JSON strings into `JSONObject` objects.

5.5.10.4 Discussion and sample code

The program named `Code` (see *Listing 6* (p. 2257)) consists of some old code and some new code. The program begins just like the program that I explained in the earlier page titled *Json0215: Encoding JSON Strings*²¹⁸ . The beginning portion of the program is used solely to create JSON data in string format and to store the individual strings as elements in an `ArrayList` object.

This code constructs three `JSONObject` objects and saves them in an `ArrayList` object. Then it transforms each `JSONObject` object into a `String` object and saves the strings in a second `ArrayList` object. The new code decodes the strings into `JSONObject` objects using a **parse** method from the `JSONValue` class and saves them in a third `ArrayList` object.

Then the new code decodes the strings into `JSONObject` objects using a **parse** method from the `JSONParser` class and saves them in a fourth `ArrayList` object.

The contents of both lists of `JSONObject` objects are displayed on the computer screen after they are populated with decoded data from the JSON strings.

²¹⁸<http://cnx.org/contents/5sRB9gpG:16t-k2Np>

5.5.10.4.1 Decode and display using the JSONValue class

I will explain this program in fragments, and will begin at the point where the new code begins. The first fragment is shown in Listing 1 (p. 2254) .

Listing 1 . Decode and display using the JSONValue class.

```
//Create a container for decoded JSON strings.
ArrayList <JSONObject> listC = new ArrayList<JSONObject>();

//Decode and display JSON strings using the parse method of the
// JSONValue class
System.out.println("Decode using JSONValue class");
decodeC(listB,listC);
display(listC);
System.out.println();//blank line
```

Immediately prior to the code in Listing 1 (p. 2254) , three JSON strings are stored as elements in an **ArrayList** object referred to as **listB** .

Listing 1 (p. 2254) begins by instantiating a new **ArrayList** object, referred to as **listC** that will receive the decoded versions of the JSON strings as type **JSONObject** objects. Then Listing 1 (p. 2254) calls the method named **decodeC** passing the list of JSON strings and the empty list as parameters.

5.5.10.4.2 The method named decodeC

The method named **decodeC** is shown in its entirety in Listing 2 (p. 2254) .

Listing 2 . The method named decodeC.

```
static void decodeC(ArrayList input,ArrayList output){
    String temp = null;
    Iterator<String> iterator = input.iterator();
    while (iterator.hasNext()){
        temp = iterator.next();
        output.add(JSONValue.parse(temp));
    }//end while loop
} //end decodeC
```

This method decodes a list of JSON strings into **JSONObject** objects using a static **parse** method of the **JSONValue** class. The resulting **JSONObject** objects are added to the empty **ArrayList** object received as an incoming parameter. When the method returns, that list contains one **JSONObject** object for each JSON string contained in the incoming **ArrayList** object.

5.5.10.4.3 Display contents of JSONObject objects

Returning now to the code in Listing 1 (p. 2254) , the next statement calls the **display** method passing the now-populated **listC** as a parameter. At this point, the **JSONObject** objects stored in **listC** contain the information that was extracted from the JSON strings by the **parse** method of the **JSONValue** class.

The **display** method is shown in its entirety in Listing 3 (p. 2255) .

Listing 3 . The display method.

```
static void display(ArrayList input){
    JSONObject temp = null;
    Iterator<JSONObject> iterator = input.iterator();
    while (iterator.hasNext()){
        temp = iterator.next();
        System.out.print("Name: " + temp.get("name"));
        System.out.print(" Age: " + temp.get("age"));
        System.out.println(" Is student? " + temp.get("student"));
    }//end while loop
} //end display
```

This method uses the `get` method inherited from the `HashMap` class to get and display the values in a list of `JSONObject` objects for a known set of keys. This is plain-vanilla Java code and shouldn't require further explanation. The results of this call to the `display` method are shown in the top half of Figure 1 (p. 2255) .

Figure 1. Program output.

```
Decode using JSONObject class
Name: Joe Age: 21 Is student? true
Name: Sue Age: 32 Is student? false
Name: Tom Age: 19 Is student? true

Decode using JSONParser class
Name: Joe Age: 21 Is student? true
Name: Sue Age: 32 Is student? false
Name: Tom Age: 19 Is student? true
```

The contents of the JSON strings for this same data were displayed in Figure 1²¹⁹ of the earlier page titled `Json0215: Encoding JSON Strings`²²⁰ .

If you compare the output in the top half of Figure 1 (p. 2255) above with the JSON string data on the earlier page, you will see that they match.

You could also make the comparison with the data in the code in the early portion of Listing 6 (p. 2257) .

5.5.10.4.4 Decode and display using the `JSONParser` class

Returning to the `main` method, the code in Listing 4 (p. 2255) calls the `decodeD` method passing the list of JSON strings along with an empty `ArrayList` object for the purpose of decoding the JSON strings using a `parse` method of the `JSONParser` class.

Listing 4 . Decode and display using the `JSONParser` class.

²¹⁹http://cnx.org/contents/5sRB9gpG:16t-k2Np#Figure_1

²²⁰<http://cnx.org/contents/5sRB9gpG:16t-k2Np>

```

//Create another container for decoded JSON strings.
ArrayList <JSONObject> listD = new ArrayList<JSONObject>();

//Decode and display JSON strings using the parse method of the
// JSONParser class
System.out.println("Decode using JSONParser class");
decoded(listB,listD);
display(listD);
System.out.println();//blank line

} //end main

```

Then the code in Listing 4 (p. 2255) calls the **display** method to display the results, producing the text in the bottom half of Figure 1 (p. 2255) .

As you can see, the results in the top and bottom halves of Figure 1 (p. 2255) match, indicating that both approaches produced the same results.

5.5.10.4.5 The method named decodedD

The method named decodedD is shown in its entirety in Listing 5 (p. 2256) .

Listing 5 . The method named decodedD.

```

static void decodedD(ArrayList input,ArrayList output){
    JSONParser parser = new JSONParser();
    String temp = null;
    Iterator<String> iterator = input.iterator();
    while (iterator.hasNext()){
        temp = iterator.next();
        try{
            //ParseException; must be caught or declared to be thrown.
            output.add(parser.parse(temp));
        }catch(ParseException pex){
            pex.printStackTrace();
        } //end catch
    } //end while loop
} //end decodedD

```

This method decodes a list of JSON strings into **JSONObject** objects using a **parse** method of the **JSONParser** class. This code is only slightly more complicated than the code shown earlier in Listing 2 (p. 2254) that uses a **parse** method of the **JSONValue** class.

The additional complexity is due mainly to the fact that the **parse** method throws a *checked* exception named **ParseException** . Because it is a checked exception, it must either be caught or declared to be thrown by the method. I elected to catch it in this program and to simply call the **printStackTrace** method (*inherited from the **Throwable** class*) in the catch block. However, the **ParseException** class provides some other methods that can be called to elaborate on the nature of the error if desired.

5.5.10.4.6 The end of the program

Returning to the **main** method in Listing 4 (p. 2255) , there is nothing more to do, so the last line in Listing 4 (p. 2255) signals the end of the program.

5.5.10.5 Run the program

I encourage you to copy the code from Listing 6 (p. 2257) . Execute the code and confirm that you get the same results as those shown in Figure 1 (p. 2255) . Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

5.5.10.6 Complete program listing

A complete listing of the program named **Code** is provided in Listing 6 (p. 2257) .

Listing 6 . The program named Code.java.

```

/*****
Copyright 2016 R.G.Baldwin

OLD CODE:
Constructs three JSONObject objects and saves them in an ArrayList.
Transforms each JSONObject object into a String object and saves the
strings in a second ArrayList object.

NEW CODE:
Decodes the strings into JSONObjects using the JSONValue parse method
and saves them in a third ArrayList object.
Decodes the strings into JSONObjects using the JSONParser class
and saves them in a fourth ArrayList object.
Displays both sets of decoded JSON strings.

Tested with Java 8, Win 7, and json-simple-1.1.1.jar.
*****/

5.5.11.2 Preface

This is a page from the book titled **The json-simple Java Library** . The book explains how to use the **json-simple** Java library to generate, transform, and query JSON text. This page provides review questions and answers for the page titled *Json0220: Decoding JSON Strings* ²²⁵ . Once you study that page, you should be able to answer the review questions in this page.

The questions and the answers in this page are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

When a question or an answer provides a link to a figure or a listing, you should open that link in a new window to make it easy to view while reading the question or the answer.

NOTE:

With respect to the screen output shown on this page, ignore the possibility of output or lack of output similar to the following:

Note: Code99.java uses unchecked or unsafe operations.

Note: Recompile with `-Xlint:unchecked` for details.

5.5.11.3 Questions

5.5.11.3.1 Question 1 .

True or False? The only way to decode or parse a JSON string with the **json-simple** library is by using the **parse** method belonging to an object of the class named **JSONParser** .

Go to answer 1 (p. 2266)

5.5.11.3.2 Question 2

True or False? Decoding or parsing a JSON string with the **json-simple** library requires the use of the **parse** method belonging to either an object of the class named **JSONParser** or an object of the class named **JSONValue** .

Go to answer 2 (p. 2266)

5.5.11.3.3 Question 3

True or False? The **parse** method belonging to the class named **JSONParser** can be called without the requirement to instantiate an object of the class.

Go to answer 3 (p. 2266)

5.5.11.3.4 Question 4

True or False? The **parse** methods of the **JSONValue** and **JSONParser** classes return an object of class **JSONString** .

Go to answer 4 (p. 2266)

5.5.11.3.5 Question 5

True or False? The code in Listing 1 (p. 2269) produces the screen output shown in Figure 1 (p. 2266) .

Go to answer 5 (p. 2266)

²²⁵<http://cnx.org/contents/5sRB9gpG:GHIZVlcF>

5.5.11.3.6 Question 6

True or False? The code in Listing 2 (p. 2269) produces the screen output shown in Figure 3 (p. 2267) .
Go to answer 6 (p. 2266)

5.5.11.3.7 Question 7

True or False? The code in Listing 3 (p. 2270) produces the screen output shown in Figure 5 (p. 2267) .
Go to answer 7 (p. 2266)

5.5.11.3.8 Question 8

True or False? The code in Listing 4 (p. 2270) produces the screen output shown in Figure 6 (p. 2268) .
Go to answer 8 (p. 2265)

5.5.11.3.9 Question 9

True or False? The code in Listing 5 (p. 2271) produces the screen output shown in Figure 7 (p. 2268) .
Go to answer 9 (p. 2265)

5.5.11.3.10 Question 10

True or False? The code in Listing 6 (p. 2271) produces the screen output shown in Figure 9 (p. 2268) .
Go to answer 10 (p. 2265)

5.5.11.3.11 Question 11

True or False? The code in Listing 7 (p. 2272) produces the screen output shown in Figure 11 (p. 2268) .
Go to answer 11 (p. 2265)

5.5.11.4 Figure index

- Figure 1 (p. 2266)
- Figure 2 (p. 2267)
- Figure 3 (p. 2267)
- Figure 4 (p. 2267)
- Figure 5 (p. 2267)
- Figure 6 (p. 2268)
- Figure 7 (p. 2268)
- Figure 8 (p. 2268)
- Figure 9 (p. 2268)
- Figure 10 (p. 2268)
- Figure 11 (p. 2268)

5.5.11.5 Listing index

- Listing 1 (p. 2269)
- Listing 2 (p. 2269)
- Listing 3 (p. 2270)
- Listing 4 (p. 2270)
- Listing 5 (p. 2271)
- Listing 6 (p. 2271)
- Listing 7 (p. 2272)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.5.11.6 Answers

5.5.11.6.1 Answer 11

True.

Go back to Question 11 (p. 2263)

5.5.11.6.2 Answer 10

False. The code in Listing 6 (p. 2271) produces the screen output with the errors shown in Figure 10 (p. 2268) .

Go back to Question 10 (p. 2263)

5.5.11.6.3 Answer 9

False. The code in Listing 5 (p. 2271) produces the screen output shown in Figure 8 (p. 2268) . The `parse` method is not `static` in the `JSONParser` class.

Go back to Question 9 (p. 2263)

5.5.11.6.4 Answer 8

True.

Go back to Question 8 (p. 2263)

5.5.11.6.5 Answer 7

True. Even though it is not necessary to instantiate an object of a class to call a *static* method belonging to that class, it is possible to instantiate an object of the `JSONValue` class and to call the *static parse* method on that object.

Go back to Question 7 (p. 2263)

5.5.11.6.6 Answer 6

False. The code in Listing 2 (p. 2269) produces the screen output with the compiler errors shown in Figure 4 (p. 2267) . The return value from the *parse* method must be cast from type `Object` to type `JSONObject` to store it in a variable of type `JSONObject` .

Go back to Question 6 (p. 2263)

5.5.11.6.7 Answer 5

False. The code in Listing 1 (p. 2269) produces the screen output with the compiler errors shown in Figure 2 (p. 2267) . The `json-simple` library does not define a class named `JSONString` .

Go back to Question 5 (p. 2262)

5.5.11.6.8 Answer 4

False. The `json-simple` library does not define a class named `JSONString` . Both *parse* methods return a reference of type `java.lang.Object` . However, it is actually a reference to an object of the class `JSONObject` , which is a subclass of `Object` several levels down. The reference must be downcast to type `JSONObject` in order to call some of the methods defined in the `JSONObject` class or to store the object's reference in a variable of type `JSONObject` .

Go back to Question 4 (p. 2262)

5.5.11.6.9 Answer 3

False. The *parse* method belonging to the class named `JSONParser` is not declared *static* . Therefore, it is an *instance method* . Instance methods can only be called on an object instantiated from the class.

Go back to Question 3 (p. 2262)

5.5.11.6.10 Answer 2

False. The *parse* method that is defined in the class named `JSONValue` is a *static* method. Static methods belonging to a class can be called without the requirement to instantiate an object of the class.

Go back to Question 2 (p. 2262)

5.5.11.6.11 Answer 1

False. The class named `JSONValue` also defines a method named *parse* that can be used to decode or parse a JSON string.

Go back to Question 1 (p. 2262)

5.5.11.7 Figures

This section contains Figures that may be referred to by one or more questions or answers.

5.5.12.1 Table of contents

- Table of contents (p. 2274)
- Preface (p. 2274)
 - Viewing tip (p. 2274)
 - * Figures (p. 2274)
 - * Listings (p. 2274)
- General background information (p. 2275)
- Discussion and sample code (p. 2275)
 - Beginning of the class and the main method (p. 2275)
 - Instantiate and populate a JSONArray object (p. 2275)
 - Populate hashMapA with a key/value pair (p. 2276)
 - Create and populate another similar JSON object (p. 2276)
 - Put the players in the game (p. 2276)
 - Write the JSON string to an output file (p. 2277)
 - The end of the program (p. 2277)
 - The contents of the output file (p. 2277)
 - Decoded output data (p. 2278)
- Run the program (p. 2278)
- Complete program listing (p. 2279)
- Miscellaneous (p. 2280)

5.5.12.2 Preface

This is a page from the book titled **The json-simple Java Library** . The book explains how to use the **json-simple** Java library to generate, transform, and query JSON text. This page explains how to encode JSON array data using the **JSONArray** class. It also shows how to write an encoded JSON string to an output text file for transport to a different programming environment.

5.5.12.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.5.12.2.1.1 Figures

- Figure 1 (p. 2277) . Prettified version of output file contents.
- Figure 2 (p. 2278) . Beginning of output file contents.
- Figure 3 (p. 2278) . Decoded output data.

5.5.12.2.1.2 Listings

- Listing 1 (p. 2275) . Beginning of the class and the main method.
- Listing 2 (p. 2275) . Instantiate and populate a JSONArray object.
- Listing 3 (p. 2276) . Populate hashMapA.
- Listing 4 (p. 2276) . Create and populate another similar JSON object.
- Listing 5 (p. 2276) . Put the players in the game.
- Listing 6 (p. 2277) . Write the JSON string to an output file.
- Listing 7 (p. 2279) . The program named Code.java.

5.5.12.3 General background information

As you learned in the page titled *Json0210: Structure of the json-simple Java Library*²³⁰, the **JSONArray** class extends the standard Java **ArrayList** class. Once you have an object of the **JSONArray** class, you have access to all of the methods defined in and inherited into the **JSONArray** class.

The sample program that follows will use the **JSONArray** class to construct a JSON string containing nested arrays and will then write the string to an output file suitable for transport to a different programming environment.

A later page in this book will read the JSON string from the file and decode it into its component parts.

5.5.12.4 Discussion and sample code

The program named **Code** (see *Listing 7 (p. 2279)*) creates a JSON string and writes it to an output file. The **json** string contains an array, which in turn contains two nested arrays.

5.5.12.4.1 Beginning of the class and the main method

I will discuss and explain the program in fragments. The first fragment is shown in *Listing 1 (p. 2275)*.

Listing 1 . Beginning of the class and the main method.

```
import org.json.simple.JSONObject;
import org.json.simple.JSONArray;
import java.io.PrintWriter;
import java.io.File;
import java.io.IOException;

class Code{

    public static void main(String[] args){
        //Create a json object. which is a subclass
        // of the Java HashMap class.
        JSONObject hashMapA = new JSONObject();

        //Populate the json object with a key/value
        // pair.
        hashMapA.put("name", "Tom");
```

There is nothing new in *Listing 1 (p. 2275)* so that code shouldn't require further explanation. Note however, that the name "Tom" will become significant in a later discussion.

5.5.12.4.2 Instantiate and populate a JSONArray object

The code in *Listing 2 (p. 2275)* instantiates and populates a **JSONArray** object.

Listing 2 . Instantiate and populate a JSONArray object.

```
JSONArray arrayListA = new JSONArray();
arrayListA.add("2-club");
arrayListA.add("3-heart");
```

²³⁰http://cnx.org/contents/5sRB9gpG:_u3ZKIdD

```

arrayListA.add("4-diamond");
arrayListA.add("5-spade");

```

Previous pages in this book have constructed JSON strings using a subclass of the Java **HashMap** class – (the **JSONObject** class) . It is worth noting that JSON strings constructed in that manner are unordered. However, JSON arrays constructed using the **JSONArray** class, which is a subclass of the **ArrayList** class, are ordered lists.

The program that I will explain in this page is intended to represent the beginning state of a two-person card game where each player receives four cards. The code in Listing 2 (p. 2275) constructs a list of the cards that will be dealt to one of the players.

5.5.12.4.3 Populate hashMapA with a key/value pair

The code in Listing 3 (p. 2276) populates the **JSONObject** object referred to as **hashMapA** with a key/value pair where the key is "cards" and the value is an object of the **JSONArray** class containing a list of strings naming specific playing cards.

Listing 3 . Populate hashMapA.

```

hashMapA.put("cards",arrayListA);

```

Note that **hashMapA** already contained a key/value pair identifying one of the players in the game named "Tom" (see Listing 1 (p. 2275)). Thus the code in Listing 1 (p. 2275) through Listing 3 (p. 2276) can be thought of as "dealing" the cards identified in Listing 2 (p. 2275) to the player named "Tom".

5.5.12.4.4 Create and populate another similar JSON object

Listing 4 (p. 2276) creates and populates a second list of playing cards and deals them to the second player in the game whose name is "Joe".

Listing 4 . Create and populate another similar JSON object.

```

JSONObject hashMapB = new JSONObject();
hashMapB.put("name","Joe");

JSONArray arrayListB = new JSONArray();
arrayListB.add("4-heart");
arrayListB.add("5-heart");
arrayListB.add("6-club");
arrayListB.add("7-diamond");
hashMapB.put("cards",arrayListB);

```

5.5.12.4.5 Put the players in the game

Now that the players have been created and have received their cards, it is time to put them in the game.

Listing 5 (p. 2276) begins by adding the two players and their card arrays to a new object of type **JSONArray** . This results in nested arrays.

Listing 5 . Put the players in the game.

```

JSONArray arrayListC = new JSONArray();
arrayListC.add(hashMapA);
arrayListC.add(hashMapB);

JSONObject hashMapC = new JSONObject();
hashMapC.put("game",arrayListC);

```

Then Listing 5 (p. 2276) creates a new **JSONObject** object to represent the game and populates it with a key/value pair where the key is "game" and the value is the array containing the two players and their card arrays.

5.5.12.4.6 Write the JSON string to an output file

Listing 6 (p. 2277) calls the **writeJSONString** method on the **JSONObject** object to encode the object into a JSON string and write it to an output file named **junk.json** .

Listing 6 . Write the JSON string to an output file.

```

try{
    PrintWriter out =
        new PrintWriter(new File("junk.json"));
    hashMapC.writeJSONString(out);
    out.flush();
}catch(IOException ex){
    ex.printStackTrace();
} //end catch

} //end main

} //end class Code

```

Note that the output file is simply a text file with the extension **.json** . Thus it can be read by any program that is capable of reading plain text files.

5.5.12.4.7 The end of the program

Listing 6 (p. 2277) also signals the end of the **main** method and the end of the program.

5.5.12.4.8 The contents of the output file

Figure 1 (p. 2277) shows a "prettified" version of the contents of the output file.

Figure 1. Prettified version of output file contents.

```

{"game":
 [
  {
    "cards":
    [
      "2-club","3-heart","4-diamond","5-spade"

```

```

    ],
    "name": "Tom"
  },
  {
    "cards":
    [
      "4-heart", "5-heart", "6-club", "7-diamond"
    ],
    "name": "Joe"
  }
]
}

```

The actual contents of the file do not contain line breaks and indentation as shown in Figure 1 (p. 2277) . Those cosmetic features were added manually to Figure 1 (p. 2277) to make it easier for you to correlate the output with the code shown earlier. Instead, the actual file consists simply of a string of characters that begins as shown in Figure 2 (p. 2278) .

Figure 2. Beginning of output file contents.

```

{"game":[{"cards":["2-club","3-heart","4-diamond","5-spade"],...

```

5.5.12.4.9 Decoded output data

As mentioned earlier, a later page in this book will read the JSON string from the file and decode it into its component parts. Figure 3 (p. 2278) shows a preview of what you will see on that page.

Figure 3. Decoded output data.

```

First Player's Name: Tom
First Player's cards
2-club
3-heart
4-diamond
5-spade

Second Player's Name: Joe
Second Player's cards
4-heart
5-heart
6-club
7-diamond

```

Figure 3 (p. 2278) shows the JSON string decoded and formatted into a display that is representative of the intent of the string – to encapsulate information about the players and their cards in a game of cards.

5.5.12.5 Run the program

I encourage you to copy the code from Listing 7 (p. 2279) . Execute the code and confirm that your output file matches that shown in Figure 2 (p. 2278) . Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

5.5.12.6 Complete program listing

Listing 7 (p. 2279) provides a complete listing of the program named **Code.java** .

Listing 7 . The program named Code.java.

```

/*****
Copyright: R.G.Baldwin 2016
Revised: 06/01/16

Creates a json string and writes it to an output
file. The json string contains an array, which in
turn contains two arrays.

Tested with Java 8, Windows 7, and
json-simple-1.1.1.
*****/

import org.json.simple.JSONObject;
import org.json.simple.JSONArray;
import java.io.PrintWriter;
import java.io.File;
import java.io.IOException;

class Code{

    public static void main(String[] args){
        //Create a json object. which is a subclass
        // of the Java HashMap class.
        JSONObject hashMapA = new JSONObject();

        //Populate the json object with a key/value
        // pair.
        hashMapA.put("name","Tom");

        //Create and populate a json array, which is
        // a subclass of the Java ArrayList class.
        JSONArray arrayListA = new JSONArray();
        arrayListA.add("2-club");
        arrayListA.add("3-heart");
        arrayListA.add("4-diamond");
        arrayListA.add("5-spade");

        //Populate the json object with a key/value
        // pair where the value is an array.
        hashMapA.put("cards",arrayListA);

        //Create and populate another similar json
        // object.
        JSONObject hashMapB = new JSONObject();
        hashMapB.put("name","Joe");

```

```

JSONArray arrayListB = new JSONArray();
arrayListB.add("4-heart");
arrayListB.add("5-heart");
arrayListB.add("6-club");
arrayListB.add("7-diamond");
hashMapB.put("cards",arrayListB);

//Create another json array and populate
// it with the two json objects created
// earlier.
JSONArray arrayListC = new JSONArray();
arrayListC.add(hashMapA);
arrayListC.add(hashMapB);

//Create another json object and populate
// it with a key/value pair where the value
// is the array from above.
JSONObject hashMapC = new JSONObject();
hashMapC.put("game",arrayListC);

try{
    //Encode the HashMap object into a
    // json String and write it to an output
    // file. Note that it is simply a text file
    // with a different extension.
    PrintWriter out =
        new PrintWriter(new File("junk.json"));
    hashMapC.writeJSONString(out);
    out.flush();
}catch(IOException ex){
    ex.printStackTrace();
} //end catch

} //end main

} //end class Code

```

5.5.12.7 Miscellaneous

This section contains a variety of miscellaneous information.

5.5.13.2 Preface

This is a page from the book titled **The json-simple Java Library** . The book explains how to use the **json-simple** Java library to generate, transform, and query JSON text. This page provides review questions and answers for the page titled *Json0225: Encoding JSON Arrays* ²³⁵ . Once you study that page, you should be able to answer the review questions in this page.

The questions and the answers in this page are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

When a question or an answer provides a link to a figure or a listing, you should open that link in a new window to make it easy to view while reading the question or the answer.

NOTE:

With respect to the screen output shown on this page, ignore the presence or absence of output similar to the following:

Note: Code99.java uses unchecked or unsafe operations.

Note: Recompile with `-Xlint:unchecked` for details.

5.5.13.3 Questions**5.5.13.3.1 Question 1 .**

True or False? The `JSONArray` class extends the standard Java `HashMap` class.

Go to answer 1 (p. 2286)

5.5.13.3.2 Question 2

True or False? The `JSONArray` class represents a true Java array. The elements in a `JSONArray` object can be accessed using the square bracket (`[]`) notation commonly associated with Java arrays.

Go to answer 2 (p. 2286)

5.5.13.3.3 Question 3

True or False? The code in Listing 1 (p. 2287) produces the screen output shown in Figure 1 (p. 2286) .

Go to answer 3 (p. 2286)

5.5.13.3.4 Question 4

True or False? The code in Listing 2 (p. 2288) produces the screen output shown in Figure 3 (p. 2287) .

Go to answer 4 (p. 2285)

5.5.13.3.5 Question 5

True or False? The code in Listing 3 (p. 2289) produces the screen output shown in Figure 5 (p. 2287) .

Go to answer 5 (p. 2285)

5.5.13.3.6 Question 6

True or False? The code in Listing 4 (p. 2289) produces the screen output shown in Figure 6 (p. 2287) .

Go to answer 6 (p. 2285)

5.5.13.3.7 Question 7

True or False? The code in Listing 5 (p. 2290) produces the screen output shown in Figure 8 (p. 2287) .

Go to answer 7 (p. 2285)

5.5.13.4 Figure index

- Figure 1 (p. 2286)
- Figure 2 (p. 2286)
- Figure 3 (p. 2287)
- Figure 4 (p. 2287)
- Figure 5 (p. 2287)

- Figure 6 (p. 2287)
- Figure 7 (p. 2287)
- Figure 8 (p. 2287)

5.5.13.5 Listing index

- Listing 1 (p. 2287)
- Listing 2 (p. 2288)
- Listing 3 (p. 2289)
- Listing 4 (p. 2289)
- Listing 5 (p. 2290)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.5.13.6 Answers

5.5.13.6.1 Answer 7

True. As a subclass of the `ArrayList` class, an object of the `JSONArray` class allows duplicate elements.
Go back to Question 7 (p. 2283)

5.5.13.6.2 Answer 6

False. The code in Listing 4 (p. 2289) produces the screen output shown in Figure 7 (p. 2287) .
Go back to Question 6 (p. 2283)

5.5.13.6.3 Answer 5

True. The `JSONArray` class provides two overloaded versions of the method named `toJSONString` . One is an instance method and the other is a `static` method. On a side note, this is also true of the class named `JSONObject` .
Go back to Question 5 (p. 2283)

5.5.13.6.4 Answer 4

False. The code in Listing 2 (p. 2288) produces the screen output shown in Figure 4 (p. 2287) . Unlike an object of the `JSONObject` class, an object of the `JSONArray` class is an *ordered* list. By this we mean that the user has precise control over where in the list each element is inserted. The user can access elements by their integer index (*position in the list*) .
Go back to Question 4 (p. 2283)

5.5.13.6.5 Answer 3

False. The code in Listing 1 (p. 2287) produces the screen output with the errors shown in Figure 2 (p. 2286). The `JSONArray` class neither defines nor inherits a method named `put`.

Go back to Question 3 (p. 2283)

5.5.13.6.6 Answer 2

False. The `JSONArray` class extends the `ArrayList` class, which implements the `List` interface. Therefore, an object of the `JSONArray` class is a list and is not an array. For example, the elements in a `JSONArray` object cannot be accessed using the square bracket (`[]`) notation commonly associated with Java arrays. Instead, the elements are accessed using the `add` and `get` methods declared in the `List` interface and inherited from the `ArrayList` class.

Go back to Question 2 (p. 2283)

5.5.13.6.7 Answer 1

False. The `JSONArray` class extends the standard Java `ArrayList` class.

Go back to Question 1 (p. 2283)

5.5.13.7 Figures

This section contains Figures that may be referred to by one or more questions or answers.

- Run the program (p. 2296)
- Complete program listing (p. 2296)
- Miscellaneous (p. 2298)

5.5.14.2 Preface

This is a page from the book titled **The json-simple Java Library** . The book explains how to use the **json-simple** Java library to generate, transform, and query JSON text. This page explains how to read a JSON string containing nested array data from a file, decode it, and display its component parts.

5.5.14.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the Figures and Listings while you are reading about them.

5.5.14.2.1.1 Figures

- Figure 1 (p. 2294) . Screen shot of raw JSON string.
- Figure 2 (p. 2294) . Display first player's name.
- Figure 3 (p. 2295) . The first player's cards.
- Figure 4 (p. 2295) . Information about the second player.

5.5.14.2.1.2 Listings

- Listing 1 (p. 2293) . Read the file containing the JSON string.
- Listing 2 (p. 2293) . Display the JSON string.
- Listing 3 (p. 2294) . Access the game array.
- Listing 4 (p. 2294) . Get information about the first player.
- Listing 5 (p. 2294) . Display first player's cards.
- Listing 6 (p. 2295) . Get and display information about the second player.
- Listing 7 (p. 2296) . The program named Code.java.

5.5.14.3 General background information

You learned how to encode JSON data containing nested arrays and how to write the encoded JSON string to an output file in the page titled [Json0225: Encoding JSON Arrays](#)²⁴⁰. The program that I will discuss and explain in the next section will read that file from the disk, decode it, and display its component parts.

5.5.14.4 Discussion and sample code

The program named **Code** (see [Listing 7 \(p. 2296\)](#)) reads and parses an input file named **junk.json**. The file contains a JSON string with nested array data.

5.5.14.4.1 Read the file containing the JSON string

I will discuss and explain this program in fragments. The first fragment is shown in [Listing 1 \(p. 2293\)](#).

Listing 1. Read the file containing the JSON string.

```
class Code{

    public static void main(String[] args){
        //Instantiate a JSONObject object, which is a subclass of the
        // Java HashMap class.
        JSONObject jsonMap = null;
        try{
            //Read json string from a file and parse it into a HashMap.
            jsonMap =
                (JSONObject)(JSONValue.parse(new FileReader("junk.json")));
        }catch(IOException ex){
            ex.printStackTrace();
        }//end catch
    }
}
```

The code in [Listing 1 \(p. 2293\)](#) shows the beginning of the class and the beginning of the **main** method. This code reads the JSON string from the input file named **junk.json** and parses the data into an object of type **JSONObject**.

There is nothing new in [Listing 1 \(p. 2293\)](#) so the code shouldn't need further explanation. When the code in [Listing 1 \(p. 2293\)](#) has finished executing, all of the information from the JSON string in the file is encapsulated in the object of type **JSONObject** referred to as **jsonMap**.

5.5.14.4.2 Display the JSON string

The code in [Listing 2 \(p. 2293\)](#) displays the raw JSON string followed by a blank line.

Listing 2. Display the JSON string.

```
System.out.println("json string: " + jsonMap);
System.out.println();//blank line
```

This code produces the screen output shown by the screen shot in [Figure 1 \(p. 2294\)](#).

²⁴⁰<http://cnx.org/contents/5sRB9gpG:6KpbQ6Wn>

Figure 1. Screen shot of raw JSON string.

```
json string: {"game":[{"cards":["2-club","3-heart","4-diamond","5-spade"],"name":
:"Tom"}, {"cards":["4-heart","5-heart","6-club","7-diamond"],"name":"Joe"}]}
```

Note that the line break in Figure 1 (p. 2294) was inserted by the operating system while displaying the string in the command-line window. The line break does not exist in the data in the file.

5.5.14.4.3 Access the game array

Listing 3 (p. 2294) calls the `get` method inherited from the `HashMap` class to get the game array into an object of type `JSONArray`, which is a subclass of the `ArrayList` class.

Listing 3. Access the game array.

```
JSONArray gameArrayList = (JSONArray)jsonMap.get("game");
```

5.5.14.4.4 Get information about the first player

Recall that a `JSONArray` object is an ordered list as a subclass of the `ArrayList` class. The `get` method inherited from the `ArrayList` class can be used to access elements in the list on the basis of a zero-based index. At this point, information about the first player is stored in the list as an object of type `JSONObject`. (*It is actually stored as type `Object` and must be downcast to type `JSONObject` in order to do much with it.*)

Listing 4 (p. 2294) begins by accessing the element at an index value of zero, which is the object containing information about the first player.

Listing 4. Get information about the first player.

```
JSONObject firstPlayerMap = (JSONObject)gameArrayList.get(0);
System.out.println("First Player's Name: " +
    firstPlayerMap.get("name"));
```

Then Listing 4 (p. 2294) uses the `get` method inherited from the `HashMap` class to get and display the value associated with the key "name". This produces the screen output shown in Figure 2 (p. 2294).

Figure 2. Display first player's name.

```
First Player's Name: Tom
```

5.5.14.4.5 Display first player's cards

Listing 5 (p. 2294) begins by using the `get` method of the `HashMap` class to access the `JSONArray` object that is the value for the key "cards".

Listing 5. Display first player's cards.

```

JSONArray firstPlayerCardsList =
    (JSONArray)firstPlayerMap.get("cards");

System.out.println("First Player's cards");

Iterator<String> iterator = firstPlayerCardsList.iterator();
while (iterator.hasNext()) {
    System.out.println(iterator.next());
} //end while loop

```

Then Listing 5 (p. 2294) uses an iterator to iterate through the **JSONArray** object and to display each of the cards in the array, (*which is actually a list at this point*) . This code produces the output shown in Figure 3 (p. 2295) .

Figure 3. The first player's cards.

```

First Player's cards
2-club
3-heart
4-diamond
5-spade

```

5.5.14.4.6 Get and display information about the second player

Listing 6 (p. 2295) uses similar code to get and display information about the second player.

Listing 6 . Get and display information about the second player.

```

System.out.println();
JSONObject secondPlayerMap = (JSONObject)gameArrayList.get(1);
System.out.println("Second Player's Name: " +
    secondPlayerMap.get("name"));

JSONArray secondPlayerCardsList =
    (JSONArray)secondPlayerMap.get("cards");
System.out.println("Second Player's cards");
iterator = secondPlayerCardsList.iterator();
while (iterator.hasNext()) {
    System.out.println(iterator.next());
} //end while loop

} //end main

} //end class Code

```

This code produces the screen output shown in Figure 4 (p. 2295) .

Figure 4. Information about the second player.

```

Second Player's Name: Joe
Second Player's cards
4-heart
5-heart
6-club
7-diamond

```

5.5.14.4.7 The end of the program

Listing 6 (p. 2295) signals the end of the `main` method and the end of the program.

5.5.14.5 Run the program

Click here ²⁴¹ to download a zip file containing a JSON data file named `junk.json` that can be used to experiment with this program.

I encourage you to copy the code from Listing 7 (p. 2296) . Execute the code and confirm that you get the same results as those shown in Figure 1 (p. 2294) through Figure 4 (p. 2295) . Experiment with the code, making changes, and observing the results of your changes. Make certain that you can explain why your changes behave as they do.

5.5.14.6 Complete program listing

A complete listing of the program named `Code` is provided in Listing 7 (p. 2296) .

Listing 7 . The program named `Code.java`.

```

/*****
Copyright: R.G.Baldwin 2016
Revised: 06/01/16

Reads a json string from a file, parses, and
displays some of its parts.

Tested with Java 8, Windows 7, and
json-simple-1.1.1.
*****/

import org.json.simple.JSONObject;
import org.json.simple.JSONArray;

5.5.15 Json0230R: Review²⁴²

Revised: Tue Jun 07 10:33:04 CDT 2016

This page is included in the following Books:

- *The json-simple Java Library* ²⁴³ .
- *INEW2338 - Advanced Java Programming* ²⁴⁴
- *Object-Oriented Programming (OOP) with Java* ²⁴⁵

5.5.15.1 Table of Contents

- Table of Contents (p. 2299)
- Preface (p. 2299)
- Questions (p. 2300)
 - Question 1 (p. 2300)
 - Question 2 (p. 2300)
 - Question 3 (p. 2300)
 - Question 4 (p. 2300)
- Figure index (p. 2300)
- Listing index (p. 2300)
- Answers (p. 2302)
 - Answer 4 (p. 2302)
 - Answer 3 (p. 2302)
 - Answer 2 (p. 2302)
 - Answer 1 (p. 2302)
- Figures (p. 2302)
- Listings (p. 2303)
- Miscellaneous (p. 2307)

5.5.15.2 Preface

This is a page from the book titled **The json-simple Java Library** . The book explains how to use the **json-simple** Java library to generate, transform, and query JSON text. This page provides review questions and answers for the page titled **Json0230: Decoding JSON Arrays** ²⁴⁶ . Once you study that page, you should be able to answer the review questions in this page.

The questions and the answers in this page are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back again.

When a question or an answer provides a link to a figure or a listing, you should open that link in a new window to make it easy to view while reading the question or the answer.

NOTE:

With respect to the screen output shown on this page, ignore the presence or absence of output similar to the following:

5.5.15.3 Questions

5.5.15.3.1 Question 1 .

True or False? The code in Listing 1 (p. 2303) produces the screen output shown in Figure 1 (p. 2302) .
Go to answer 1 (p. 2302)

5.5.15.3.2 Question 2

True or False? The code in Listing 2 (p. 2304) produces the screen output shown in Figure 3 (p. 2302) .
Go to answer 2 (p. 2302)

5.5.15.3.3 Question 3

True or False? The code in Listing 3 (p. 2305) produces the screen output shown in Figure 5 (p. 2303) .
Go to answer 3 (p. 2302)

5.5.15.3.4 Question 4

True or False? The code in Listing 4 (p. 2306) produces the screen output shown in Figure 7 (p. 2303) .
Go to answer 4 (p. 2302)

5.5.15.4 Figure index

- Figure 1 (p. 2302)
- Figure 2 (p. 2302)
- Figure 3 (p. 2302)
- Figure 4 (p. 2302)
- Figure 5 (p. 2303)
- Figure 6 (p. 2303)
- Figure 7 (p. 2303)

5.5.15.5 Listing index

- Listing 1 (p. 2303)
- Listing 2 (p. 2304)
- Listing 3 (p. 2305)
- Listing 4 (p. 2306)

What is the meaning of the following two images?

These images were inserted here simply to insert some space between the questions and the answers to keep them from being visible on the screen at the same time.

This image was also inserted for the purpose of inserting space between the questions and the answers.

5.5.15.6 Answers

5.5.15.6.1 Answer 4

True.

Go back to Question 4 (p. 2300)

5.5.15.6.2 Answer 3

False. The code in Listing 3 (p. 2305) produces the screen output with the error shown in Figure 6 (p. 2303)

Go back to Question 3 (p. 2300)

5.5.15.6.3 Answer 2

False. The code in Listing 2 (p. 2304) produces the screen output with the error shown in Figure 4 (p. 2302)

Go back to Question 2 (p. 2300)

5.5.15.6.4 Answer 1

False. The code in Listing 1 (p. 2303) produces the screen output with the error shown in Figure 2 (p. 2302)

Go back to Question 1 (p. 2300)

5.5.15.7 Figures

This section contains Figures that may be referred to by one or more questions or answers.

Figure 1

Tom

Figure 2

```
Code01.java:36: error: incompatible types: Object cannot be converted to String
    String temp02 = temp01.get("Name");

GAME 2302 - Mathematical Applications for Game Development

6.1 Jy0040: GAME2302: Mathematical Applications for Game Development¹

6.1.1 Table of Contents

- Welcome (p. 2311)
- Miscellaneous (p. 2311)

6.1.2 Welcome

Click the link to view the course material for GAME 2302 Mathematical Applications for Game Development², which I teach at Austin Community College in Austin, TX.

Official information about the course

The college website for this course is: <http://www.austincc.edu/baldwin/>³.

As of December 2012, the description for this course reads:

"GAME 2302 - Mathematical Applications for Game Development

Presents applications of mathematics and science in game and simulation programming. Includes the utilization of matrix and vector operations, kinematics, and Newtonian principles in games and simulations. Also covers code optimization."

6.1.3 Miscellaneous

This section contains a variety of miscellaneous information.

Chapter 7

OOB Self-Assessment

7.1 Ap0005: Preface to OOB Self-Assessment¹

Revised: Fri Apr 08 22:51:58 CDT 2016

This page is included in the following Books:

- *Java OOB Self-Assessment* ²
- *Object-Oriented Programming (OOB) with Java* ³

7.1.1 Welcome

Welcome to my group of modules titled *Java OOB Self-Assessment* .

This is a self-assessment test designed to help you determine how much you know about object-oriented programming (OOB) using Java.

In addition to being a self-assessment test, it is also a major learning tool. Each module consists of about ten to twenty questions with answers and explanations on two or three specific topics. In many cases, the explanations are extensive. You may find those explanations to be very educational in your journey towards understanding OOB using Java.

To give you some idea of the scope of this self-assessment test, when you can successfully answer most of the questions in modules Ap0010 ⁴ through Ap0140 ⁵ , your level of knowledge will be roughly equivalent to that of a student who has successfully completed an AP Computer Science course in a U.S. high school up to but not including data structures. This is based on my interpretation of the College Board's Computer Science A Course Description ⁶ .

7.1.2 Miscellaneous

This section contains a variety of miscellaneous information.

7.2.2 Preface

This module is part of a self-assessment test designed to help you determine how much you know about object-oriented programming using Java.

Questions and answers

The test consists of a series of questions (p. 2315) with answers (p. 2329) and explanations of the answers.

The questions and the answers are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back.

Programming challenge questions

The module also contains a section titled Programming challenge questions (p. 2321) . This section provides specifications for one or more programs that you should be able to write once you understand the answers to all of the questions. *(Note that it is not always possible to confine the programming knowledge requirement to this and earlier modules. Therefore, you may occasionally need to refer ahead to future modules in order to write the programs.)*

Unlike the other questions, solutions are not provided for the *Programming challenge questions* . However, in most cases, the specifications will describe the output that your program should produce.

Listings

I recommend that you open another copy of this document in a separate browser window and use the links to under Listings (p. 2328) to easily find and view the listings while you are reading about them.

7.2.3 Questions

7.2.3.1 Question 1 .

What output is produced by the program in Listing 1 (p. 2315) ?

- A. Compiler error
- B. Runtime error
- C. Hello World
- D. Goodbye Cruel World

Listing 1 . Question 1.
<pre> public class Ap001{ public static void main(String args[]){ new Worker().hello(); } //end main() } //end class definition class Worker{ public void hello(){ System.out.println("Hello World"); } //end hello() } //end class definition </pre>

Table 7.1

Answer and Explanation (p. 2334)

7.2.3.2 Question 2 .

What is the largest (algebraic) value of type int?

- A. 32767
- B. 2147483647
- C. -2147483647
- D. -32768

Answer and Explanation (p. 2333)

7.2.3.3 Question 3 .

What is the smallest (algebraic) value of type int?

- A. -2147483648
- B. -2147483647
- C. 32767
- D. -32768

Answer and Explanation (p. 2333)

7.2.3.4 Question 4 .

What two values are displayed by the program in Listing 2 (p. 2316) ?

- A. -2147483648
- B. 1.7976931348623157E308
- C. -2147483647
- D. 4.9E-324

Listing 2 . Question 4.

```

public class Ap003{
public static void main(
                String args[]){
    new Worker().printDouble();
} //end main()
} //end class definition

class Worker{
public void printDouble(){
    System.out.println(
                Double.MAX_VALUE);
    System.out.println(
                Double.MIN_VALUE);
} //end printDouble()
} //end class definition

```

Table 7.2

Answer and Explanation (p. 2332)

7.2.3.5 Question 5 .

What output is produced by the program in Listing 3 (p. 2317) ?

- A. true
- B. false
- C. 1
- D. 0

Listing 3 . Question 5.

```
public class Ap004{
public static void main(
    String args[]){
    new Worker().printBoolean();
} //end main()
} //end class definition

class Worker{
    private boolean myVar;
    public void printBoolean(){
        System.out.println(myVar);
    } //end printBoolean()
} //end class definition
```

Table 7.3

Answer and Explanation (p. 2332)

7.2.3.6 Question 6 .

What output is produced by the program shown in Listing 4 (p. 2318) ?

- A. Compiler Error
- B. Runtime Error
- C. true
- D. false

Listing 4 . Question 6.

```
public class Ap005{
public static void main(
                String args[]){
    new Worker().printBoolean();
} //end main()
} //end class definition

class Worker{
    public void printBoolean(){
        boolean myVar;
        System.out.println(myVar);
    } //end printBoolean()
} //end class definition
```

Table 7.4

Answer and Explanation (p. 2331)

7.2.3.7 Question 7 .

What output is produced by the program shown in Listing 5 (p. 2318) ?

- A. Compiler Error
- B. Runtime Error
- C. true
- D. false

Listing 5 . Question 7.

```
public class Ap006{
public static void main(
                String args[]){
    new Worker().printBoolean();
} //end main()
} //end class definition

class Worker{
    public void printBoolean(){
        boolean myVar = true;
        myVar = false;
        System.out.println(myVar);
    } //end printBoolean()
} //end class definition
```

Table 7.5

Answer and Explanation (p. 2331)

7.2.3.8 Question 8 .

The plus (+) character can be used to perform numeric addition in Java. What output is produced by the program shown in Listing 6 (p. 2319) ?

- A. Compiler Error
- B. Runtime Error
- C. true
- D. 2
- E. 1

Listing 6 . Question 8.

```

public class Ap007{
public static void main(
                String args[]){
    new Worker().printBoolean();
} //end main()
} //end class definition

class Worker{
    public void printBoolean(){
        boolean myVar = true;
        System.out.println(1 + myVar);
    } //end printBoolean()
} //end class definition

```

Table 7.6

Answer and Explanation (p. 2330)

7.2.3.9 Question 9 .

The plus (+) character can be used to perform numeric addition in Java. What output is produced by the program shown in Listing 7 (p. 2320) ?

- A. Compiler Error
- B. Runtime Error
- C. 6
- D. 6.0

Listing 7 . Question 9.

continued on next page

```

    public class Ap008{
    public static void main(
                String args[]){
        new Worker().printMixed();
    }//end main()
} //end class definition

class Worker{
    public void printMixed(){
        double x = 3;
        int y = 3;
        System.out.println(x+y);
    } //end printMixed()
} //end class definition

```

Table 7.7

Answer and Explanation (p. 2330)

7.2.3.10 Question 10 .

The slash (/) character can be used to perform numeric division in Java. What output is produced by the program shown in Listing 8 (p. 2320) ?

- A. Compiler Error
- B. Runtime Error
- C. 0.33333334
- D. 0.3333333333333333

Listing 8 . Question 10.

```

    public class Ap009{
    public static void main(
                String args[]){
        new Worker().printMixed();
    } //end main()
} //end class definition

class Worker{
    public void printMixed(){
        System.out.println(1.0/3);
    } //end printMixed()
} //end class definition

```

Table 7.8

Answer and Explanation (p. 2329)

7.2.4 Programming challenge questions

7.2.4.1 Question 11

Write the program described in Listing 9 (p. 2321) .

Listing 9 . Question 11.

```

/*File Ap0010a1.java Copyright 2012, R.G.Baldwin

Instructions to student:
This program refuses to compile without errors.

Make the necessary corrections to cause the program to
compile and run successfully to produce the output shown
below:

ITSE
2321
*****/
public class Ap0010a1{
    public static void main(String args[]){
        System.out.println("ITSE");
        new Worker().doIt();
    }//end main()
} //end class definition
//=====//

Class Worker{
    public void doIt(){
        System.out.println("2321");
    } //end doIt()
} //end class definition
//=====//

```

Table 7.9

7.2.4.2 Question 12

Write the program described in Listing 10 (p. 2322) .

Listing 10 . Question 12.

continued on next page

```

/*File Ap0010b1.java Copyright 2012, R.G.Baldwin

Instructions to student:
Beginning with the code fragment shown below, write a
method named doIt that:
1. Receives and displays an incoming parameter of type int.

The result should be similar to the following but the
values should be different each time the program is
run.

484495695
484495695
*****/
//Student is not expected to understand import directives
// at this point.
import java.util.Random;
import java.util.Date;

public class Ap0010b1{
    public static void main(String args[]){
        //Create a random number for testing. Student is not
        // expected to understand how this works at this point.
        Random random = new Random(new Date().getTime());
        int intVar = random.nextInt();

        //Student should understand the following
        int var = intVar;
        System.out.println(var);
        new Worker().doIt(var);
    }//end main()
} //end class definition
//=====//

class Worker{
    //-----//
    //Student: insert the method named doIt between these
    // lines.
    //-----//
} //end class definition
//=====//

```

Table 7.10

7.2.4.3 Question 13

Write the program described in Listing 11 (p. 2323) .

Listing 11 . Question 13.

```

/*File Ap0010c1.java Copyright 2012, R.G.Baldwin

Instructions to student:
Beginning with the code fragment shown below, write a
method named doIt that returns the largest value of type
int as type float.

The result should be 2.14748365E9
*****/
public class Ap0010c1{
    public static void main(String args[]){
        float val = new Worker().doIt();
        System.out.println(val);
    }//end main()
} //end class definition
//=====//

class Worker{
    //-----//
    //Insert the method named doIt between these lines.
    //-----//
} //end class definition
//=====//

```

Disclaimers: Financial : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

In the past, unknown individuals have copied my modules from cnx.org, converted them to Kindle books, and placed them for sale on Amazon.com showing me as the author. I neither receive compensation for those sales nor do I know who does receive compensation. If you purchase such a book, please be aware that it is a copy of a module that is freely available on cnx.org and that it was made and published without my prior knowledge.

Affiliation : I am a professor of Computer Information Technology at Austin Community College in Austin, TX.

7.2.7 Answers

7.2.7.1 Answer 10 .

D. 0.3333333333333333

7.2.7.1.1 Explanation 10

Divide floating type by integer type

This program divides the literal floating value of 1.0 by the literal integer value of 3 (*no decimal point is specified in the integer literal value*) .

Automatic conversion from narrow to wider type

To begin with, whenever division is performed between a floating type and an integer type, the integer type is automatically converted (*sometimes called promoted*) to a floating type and floating arithmetic is performed.

What is the actual floating type, float or double?

The real question here is, what is the type of the literal shown by 1.0 (*with a decimal point separating the 1 and the 0*) . Is it a **double** or a **float** ?

Type double is the default

By default, a literal floating value is treated as a **double** .

The result is type double

Consequently, this program divides a **double** type by an integer type, producing a result of type **double** . This is somewhat evident in the output, which shows about 17 digits plus a decimal point in the result. (*Recall that the maximum value for a float shown earlier had only about eight digits plus the decimal point and the exponent.*)

How can you create literals of type float?

What if you don't want your literal floating value to be treated as a **double** , but would prefer that it be treated as a **float** instead.

You can usually force this to be the case by adding a suffix of either F or f to the end of the literal value (as in *1.0F*) . If you were to modify this program to cause it to divide 1.0F by 3, the output would be 0.33333334 with only nine digits in the result.

Back to Question 10 (p. 2320)

7.2.7.2 Answer 9 .

D. 6.0

7.2.7.2.1 Explanation 9

Declare and initialize two local variables

This program declares and initializes two local variables, one of type **double** and the other of type **int** . Each variable is initialized with the integer value 3.

Automatic conversion to floating type double

However, before the value of 3 is stored in the **double** variable, it is automatically converted to type **double** .

Automatic conversion in mixed-type arithmetic

Numeric addition is performed on the two variables. Whenever addition is performed between a floating type and an integer type, the integer type is automatically converted to a floating type and floating arithmetic is performed.

A floating result

This produces a floating result. When this floating result is passed to the **println** method for display, a decimal point and a zero are displayed to indicate a floating type, even though in this case, the fractional part of the result is zero.

Back to Question 9 (p. 2319)

7.2.7.3 Answer 8 .

A. Compiler Error

7.2.7.3.1 Explanation 8

Initialize boolean variable to true

This program declares and initializes a **boolean** variable with the value *true* . Then it attempts to add the literal value 1 to the value stored in the **boolean** variable named **myVar** .

Arithmetic with boolean values is not allowed

As mentioned earlier, unlike C++, **boolean** types in Java cannot participate in arithmetic expressions.

Therefore, this program will not compile. The compiler error produced by this program under JDK 1.3 reads partially as follows:

```
Ap007.java:13: operator + cannot be applied to int,boolean
System.out.println(1 + myVar);
```

Table 7.17

Back to Question 8 (p. 2319)

7.2.7.4 Answer 7 .

D. false

7.2.7.4.1 Explanation 7

Format for variable initialization

This program declares a local **boolean** variable and initializes it to the value *true* . All variables, local or otherwise, can be initialized in this manner provided that the expression on the right of the equal sign evaluates to a value that is assignment compatible with the type of the variable. (*I will have more to say about assignment compatibility in a future module*) .

Value is changed before display

However, before calling the **println** method to display the initial value of the variable, the program uses the assignment operator (=) to assign the value *false* to the variable. Thus, when it is displayed, the value is *false* .

Back to Question 7 (p. 2318)

7.2.7.5 Answer 6 .

A. Compiler Error

7.2.7.5.1 Explanation 6

A local boolean variable

In this program, the primitive variable named **myVar** is a local variable belonging to the method named **printBoolean** .

Local variables are not automatically initialized

Unlike instance variables, if you fail to initialize a local variable, the variable is not automatically initialized.

Cannot access value from uninitialized local variable

If you attempt to access and use the value from an uninitialized local variable before you assign a value to it, you will get a compiler error. The compiler error produced by this program under JDK 1.3 reads partially as follows:

```
Ap005.java:13: variable myVar might not have been initialized
System.out.println(myVar);
```

Table 7.18

Must initialize or assign value to all local variables

Thus, the programmer is responsible for either initializing all local variables, or assigning a value to them before attempting to access their value with code later in the program. The good news is that the system won't allow you to compute with garbage left over in memory occupied by variables, either local variables or member variables.

Back to Question 6 (p. 2317)

7.2.7.6 Answer 5 .

B. false

7.2.7.6.1 Explanation 5**The boolean type**

In this program, the primitive variable named `myVar` is an instance variable of the type `boolean` .

What is an instance variable?

An instance variable is a variable that is declared inside a class, outside of all methods and constructors of the class, and is not declared static. Every object instantiated from the class has one. That is why it is called an instance variable.

Cannot use uninitialized variables in Java

One of the great things about Java is that it is not possible to make the mistake of using variables that have not been initialized.

Can initialize when declared

All Java variables can be initialized when they are declared.

Member variables are automatically initialized

If the programmer doesn't initialize the variables declared inside the class but outside of a method (*often referred to as member variables as opposed to local variables*) , they are automatically initialized to a default value. The default value for a `boolean` variable is false.

Did you know the boolean default value?

I wouldn't be overly concerned if you had selected the answer A. true, because I wouldn't necessarily expect you to memorize the default initialization value.

Great cause for concern

However, I would be very concerned if you selected either C. 1 or D. 0.

Java has a true boolean type

Unlike C++, Java does not represent true and false by the numeric values of 1 and 0. (*At least the numeric values that represent true and false are not readily accessible by the programmer.*)

Thus, you cannot include boolean types in arithmetic expressions, as is the case in C++.

Back to Question 5 (p. 2317)

7.2.7.7 Answer 4 .

- B. 1.7976931348623157E308
- D. 4.9E-324

7.2.7.7.1 Explanation 4**Floating type versus integer type**

If you missed this one, shame on you!

I didn't expect you to memorize the maximum and minimum values represented by the floating type double, but I did expect you to be able to distinguish between the display of a floating value and the display of an integer value.

Both values are positive

Note that both of the values given above are positive values.

Unlike the integer types discussed earlier, the constants named `MAX_VALUE` and `MIN_VALUE` don't represent the ends of a signed number range for type `double`. Rather, they represent the largest and smallest (*non-zero*) values that can be expressed by the type.

An indication of granularity

`MIN_VALUE` is an indication of the degree of granularity of values expressed as type `double`. Any `double` value can be treated as either positive or negative.

Two floating types are available

Java provides two floating types: `float` and `double`. The `double` type provides the greater range, or to use another popular terminology, it is the *wider* of the two.

What is the value range for a float?

In case you are interested, using the same syntax as above, the value range for type `float` is from 1.4E-45 to 3.4028235E38

Double is often the default type

There is another thing that is significant about type `double`. In many cases where a value is automatically converted to a floating type, it is converted to type `double` rather than to type `float`. This will come up in future modules.

Back to Question 4 (p. 2316)

7.2.7.8 Answer 3 .

A. -2147483648

7.2.7.8.1 Explanation 3

Could easily have guessed

As a practical matter, you had one chance in two of guessing the correct answer to this question, already having been given the value of the largest algebraic value for type `int`.

And the winner is ...

Did you answer B. -2147483647? – WRONG

If so, you may be wondering why the most negative value isn't equal to the negative version of the most positive value?

A twos-complement characteristic

Without going into the details of why, it is a well-known characteristic of binary twos-complement notation that the value range extends one unit further in the negative direction than in the positive direction.

What about the other two values?

Do the values of -32768 and 32767 in the set of multiple-choice answers to this question represent anything in particular?

Yes, they represent the extreme ends of the value range for a 16-bit binary number in twos-complement notation.

Does Java have a 16-bit integer type?

Just in case you are interested, the `short` type in Java is represented in 16-bit binary twos-complement signed notation, so this is the value range for type `short`.

What about type `byte`?

Similarly, a value of type `byte` is represented in 8-bit binary twos-complement signed notation, with a value range extending from -128 to 127.

Back to Question 3 (p. 2316)

7.2.7.9 Answer 2 .

B. 2147483647

7.2.7.9.1 Explanation 2

First question on types

This is the first question on Java types in this group of self-assessment modules.

32-bit signed twos-complement integers

In Java, values of type `int` are stored as 32-bit signed integers in twos-complement notation.

Can you calculate the values?

There are no unsigned integer types in Java, as there are in C++. If you are handy with binary notation, you could calculate the largest positive value that can be stored in 32 bits in twos-complement notation.

See documentation for the Integer class

Otherwise, you can visit the documentation¹⁰ for the `Integer` class, which provides a symbolic constant (*public static final variable*) named `MAX_VALUE`. The description of `MAX_VALUE` reads as follows:

"The largest value of type int. The constant value of this field is 2147483647."

Back to Question 2 (p. 2316)

7.2.7.10 Answer 1 .

C. Hello World

7.2.7.10.1 Explanation 1

The answer to this first question is intended to be easy. The purpose of the first question is to introduce you to the syntax that will frequently be used for program code in this group of self-assessment modules.

The controlling class and the main method

In this example, the class named `Ap001` is the *controlling class*. It contains a method named `main`, with a signature that matches the required signature for the `main` method. When the user executes this program, the Java virtual machine automatically calls the method named `main` in the controlling class.

Create an instance of Worker

The `main` method uses the `new` operator along with the default constructor for the class named `Worker` to create a new instance of the class named `Worker` (*an object of the Worker class*). This is often referred to as instantiating an object.

A reference to an anonymous object

The combination of the `new` operator and the default constructor for the `Worker` class returns a reference to the new object. In this case, the object is instantiated as an *anonymous object*, meaning that the object's reference is not saved in a named reference variable. (*Instantiation of a non-anonymous object will be illustrated later.*)

Call hello method on Worker object

The main method contains a single executable statement.

As soon as the reference to the new object is returned, the single statement in the `main` method calls the `hello` method on that reference.

Output to standard output device

This causes the `hello` method belonging to the new object (*of the class named Worker*) to execute. The code in the `hello` method calls the `println` method on the `static` variable of the `System` class named `out`.

Lots of OOP embodied in the hello method

I often tell my students that I can tell a lot about whether a student really understands object-oriented programming in Java by asking them to explain everything that they know about the following statement:

```
System.out.println("Hello World");
```

I would expect the answer to consume about ten to fifteen minutes if the student really understands Java OOP.

The one-minute version

¹⁰<http://cnx.org/content/m45117>

When the virtual machine starts a Java application running, it automatically instantiates an I/O stream object linked to the standard output device (*normally the screen*) and stores a reference to that object in the **static** variable named **out** belonging to the class named **System** .

Call the **println** instance method on **out**

Calling the **println** method on that reference, and passing a literal string ("*Hello World*") to that method causes the contents of the literal **String** object to be displayed on the standard output device.

Display *Hello World* on the screen

In this case, this causes the words *Hello World* to be displayed on the standard output device. This is the answer to the original question.

Time for **main** method to terminate

When the **hello** method returns, the **main** method has nothing further to do, so it terminates. When the **main** method terminates in a Java application, the application terminates and returns control to the operating system. This causes the system prompt to reappear.

A less-cryptic form

A less cryptic form of this program is shown in Listing 17 (p. 2335) .

Listing 17 . Answer 1.

```
public class Ap002{
public static void main(
                String args[]){
    Worker refVar = new Worker();
    refVar.hello();
} //end main()
} //end class definition
class Worker{

    public void hello(){
        System.out.println("Hello World");
    } //end hello()
} //end class definition
```

Table 7.19

Decompose single statement into two statements

In this version, the single statement in the earlier version of the **main** method is replaced by two statements.

A non-anonymous object

In the class named **Ap002** shown in Listing 2 (p. 2316) , the object of the class named **Worker** is not instantiated anonymously. Rather, a new object of the **Worker** class is instantiated and the object's reference is stored in (*assigned to*) the named reference variable named **refVar** .

Call **hello** method on named reference

Then the **hello** method is called on that reference in a separate statement.

Produces the same result as before

The final result is exactly the same as before. The only difference is that a little more typing is required to create the source code for the second version.

Will often use anonymous objects

In order to minimize the amount of typing required, I will probably use the anonymous form of instantiation whenever appropriate in these modules.

Now that you understand the framework ...

Now that you understand the framework for the program code, I can present more specific questions. Also, the explanations will usually be shorter.

7.3.2 Preface

This module is part of a self-assessment test designed to help you determine how much you know about object-oriented programming using Java.

Questions and answers

The test consists of a series of questions (p. 2337) with answers (p. 2355) and explanations of the answers.

The questions and the answers are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back.

Programming challenge questions

The module also contains a section titled Programming challenge questions (p. 2348) . This section provides specifications for one or more programs that you should be able to write once you understand the answers to all of the questions. *(Note that it is not always possible to confine the programming knowledge requirement to this and earlier modules. Therefore, you may occasionally need to refer ahead to future modules in order to write the programs.)*

Unlike the other questions, solutions are not provided for the *Programming challenge questions* . However, in most cases, the specifications will describe the output that your program should produce.

Listings

I recommend that you open another copy of this document in a separate browser window and use the links to under Listings (p. 2354) to easily find and view the listings while you are reading about them.

¹¹This content is available online at <<http://cnx.org/content/m45286/1.6/>>.

7.3.3 Questions

7.3.3.1 Question 1 .

What output is produced by the program shown in Listing 1 (p. 2337) ?

- A. Compiler Error
- B. Runtime Error
- C. 3.0
- D. 4.0
- E. 7.0

Listing 1 . Listing for Question 1.
<pre> public class Ap010{ public static void main(String args[]){ new Worker().doAsg(); } //end main() } //end class definition class Worker{ public void doAsg(){ double myVar; myVar = 3.0; myVar += 4.0; System.out.println(myVar); } //end doAsg() } //end class definition </pre>

7.3.7 Answers

7.3.7.1 Answer 15

C. -3 2

7.3.7.1.1 Explanation 15**String concatenation**

This program uses **String** concatenation, which has not been previously discussed in this group of self-assessment modules.

In this case, the program executes both an integer divide operation and an integer modulus operation, using **String** concatenation to display both results on a single line of output.

Quotient = -3 with a remainder of 2

Thus, the displayed result is the integer quotient followed by the remainder.

What is String concatenation?

If either operand of the plus (+) operator is of type **String**, no attempt is made to perform arithmetic addition. Rather, the other operand is converted to a **String**, and the two strings are concatenated.

A space character, " "

The string containing a space character (" ") in this expression appears as the right operand of one plus operator and as the left operand of the other plus operator.

If you already knew about **String** concatenation, you should have been able to figure out the correct answer to the question on the basis of the answers to earlier questions in this module.

Back to Question 15 (p. 2347)

7.3.7.2 Answer 14

D. NaN

7.3.7.2.1 Explanation 14**Floating modulus operation involves floating divide**

The modulus operation with floating operands and 0.0 as the right operand produces **NaN**, which stands for *Not a Number*.

What is the actual value of Not a Number?

A symbolic constant that is accessible as **Double.NaN** specifies the value that is returned in this case. Be careful what you try to do with it. It has some peculiar behavior of its own.

Back to Question 14 (p. 2346)

7.3.7.3 Answer 13

D. 1.5499999999999996

7.3.7.3.1 Explanation 13**A totally incorrect result**

Unfortunately, due to floating arithmetic inaccuracy, the modulus operation in this program produces an entirely incorrect result.

The result should be 0.0, and that is the result produced by my hand calculator.

Terminates one step too early

However, this program terminates the repetitive subtraction process one step too early and produces an incorrect remainder.

Be careful

This program is included here to emphasize the need to be very careful how you interpret the result of performing modulus operations on floating operands.

Back to Question 13 (p. 2346)

7.3.7.4 Answer 12

C. -0.010999999999999996

7.3.7.4.1 Explanation 12

Modulus operator can be used with floating types

In this case, the program returns the remainder that would be produced by dividing a double value of -0.11 by a double value of 0.033 and terminating the divide operation at the beginning of the fractional part of the quotient.

Say that again

Stated differently, the result of the modulus operation is the remainder that results after

- subtracting the right operand from the left operand an integral number of times, and
- terminating the repetitive subtraction process when the result of the subtraction is less than the right operand

Modulus result is not exact

According to my hand calculator, taking into account the fact that the left operand is negative, this operation should produce a modulus result of -0.011. As you can see, the result produced by the application of the modulus operation to floating types is not exact.

Back to Question 12 (p. 2345)

7.3.7.5 Answer 11

B. Runtime Error

7.3.7.5.1 Explanation 11

Integer modulus involves integer divide

The modulus operation with integer operands involves an integer divide.

Therefore, it is subject to the same kind of problem as an ordinary integer divide when the right operand has a value of zero.

Program produces a runtime error

In this case, the program produced a runtime error that terminated the program. The error produced by JDK 1.3 is as follows:

```
Exception in thread "main" java.lang.ArithmeticException: / by zero
  at Worker.doMod(Ap020.java:14)
  at Ap020.main(Ap020.java:6)
```

Table 7.42

Dealing with the problem

As with integer divide, you can either test the right operand for a zero value before performing the modulus operation, or you can deal with the problem after the fact using try-catch.

Back to Question 11 (p. 2344)

7.3.7.6 Answer 10

D. -2

7.3.7.6.1 Explanation 10

What is a modulus operation?

In elementary terms, we like to say that the modulus operation returns the remainder that results from a divide operation.

In general terms, that is true.

Some interesting behavior

However, the modulus operation has some interesting behaviors that are illustrated in this and the next several questions.

This program returns the modulus of -11 and 3, with -11 being the left operand.

What is the algebraic sign of the result?

Here is a rule:

The result of the modulus operation takes the sign of the left operand, regardless of the sign of the quotient and regardless of the sign of the right operand. In this program, that produced a result of -2.

Changing the sign of the right operand would **not** have changed the sign of the result.

Exercise care with sign of modulus result

Thus, you may need to exercise care as to how you interpret the result when you perform a modulus operation having a negative left operand.

Back to Question 10 (p. 2344)

7.3.7.7 Answer 9

C. Infinity

7.3.7.7.1 Explanation 9

Floating divide by zero

This program attempts to divide the **double** value of 11 by the **double** value of zero.

No runtime error with floating divide by zero

In the case of floating types, an attempt to divide by zero does not produce a runtime error. Rather, it returns a value that the **println** method interprets and displays as Infinity.

What is the actual value?

The actual value returned by this program is provided by a **static final** variable in the **Double** class named **POSITIVE_INFINITY**.

*(There is also a value for **NEGATIVE_INFINITY**, which is the value that would be returned if one of the operands were a negative value.)*

Is this a better approach?

Is this a better approach than throwing an exception as is the case for integer divide by zero?

I will let you be the judge of that.

In either case, you can test the right operand before the divide to assure that it isn't equal to zero.

Cannot use exception handling in this case

For floating divide by zero, you cannot handle the problem by using try-catch.

However, you can test the result following the divide to see if it is equal to either of the infinity values mentioned above.

Back to Question 9 (p. 2343)

7.3.7.8 Answer 8

B. Runtime Error

7.3.7.8.1 Explanation 8

Dividing by zero

This program attempts to divide the `int` value of 11 by the `int` value of zero.

Integer divide by zero is not allowed

This produces a runtime error and terminates the program.

The runtime error is as follows under JDK 1.3:

```
Exception in thread "main" java.lang.ArithmeticException: / by zero
    at Worker.doMixed(Ap017.java:14)
    at Ap017.main(Ap017.java:6)
```

Table 7.43

Two ways to deal with this sort of problem

One way is to test the right operand before each divide operation to assure that it isn't equal to zero, and to take appropriate action if it is.

A second (*possibly preferred*) way is to use exception handling and surround the divide operation with a `try` block, followed by a `catch` block for the type

```
java.lang.ArithmeticException.
```

Table 7.44

The code in the catch block can be designed to deal with the problem if it occurs. (*Exception handling will be discussed in a future module.*)

Back to Question 8 (p. 2342)

7.3.7.9 Answer 7

E. 33

7.3.7.9.1 Explanation 7

Integer truncation

This program illustrates the integer truncation that results when the division operator is applied to operands of the integer types.

The result of simple long division

We all know that when we divide 101 by 3, the result is 33.666666 with the sixes extending out to the limit of our arithmetic accuracy.

The result of rounding

If we round the result to the next closest integer, the result is 34.

Integer division does not round

However, when division is performed using operands of integer types in Java, the fractional part is simply discarded (*not rounded*).

The result is the whole number result without regard for the fractional part or the remainder.

Thus, with integer division, $101/3$ produces the integer value 33.

If either operand is a floating type ...

If either operand is one of the floating types,

- the integer operand will be converted to the floating type,
- the result will be of the floating type, and
- the fractional part of the result will be preserved to some degree of accuracy

Back to Question 7 (p. 2342)

7.3.7.10 Answer 6

D. -2147483647

7.3.7.10.1 Explanation 6**Danger, integer overflow ahead!**

This program illustrates a very dangerous situation involving arithmetic using operands of integer types. This situation involves a condition commonly known as *integer overflow* .

The good news

The good news about doing arithmetic using operands of integer types is that as long as the result is within the allowable value range for the wider of the integer types, the results are exact (*floating arithmetic often produces results that are not exact*) .

The bad news

The bad news about doing arithmetic using operands of integer types is that when the result is not within the allowable value range for the wider of the integer types, the results are garbage, having no usable relationship to the correct result (*floating arithmetic has a high probability of producing approximately correct results, even though the results may not be exact*).

For this specific case ...

As you can see by the answer to this question, when a value of 2 was added to the largest positive value that can be stored in type `int` , the incorrect result was a very large negative value.

The result is simply incorrect. (*If you know how to do binary arithmetic, you can figure out how this happens.*)

No safety net in this case – just garbage

Furthermore, there was no compiler error and no runtime error. The program simply produced an incorrect result with no warning.

You need to be especially careful when writing programs that perform arithmetic using operands of integer types. Otherwise, your programs may produce incorrect results.

Back to Question 6 (p. 2341)

7.3.7.11 Answer 5

C. 4.294967294E9

7.3.7.11.1 Explanation 5**Mixed-type arithmetic**

This program illustrates the use of arithmetic operators with operands of different types.

Declare and initialize an int

The method named `doMixed` declares a local variable of type `int` named `myIntVar` and initializes it with the largest positive value that can be stored in type `int` .

Evaluate an arithmetic expression

An arithmetic expression involving `myIntVar` is evaluated and the result is passed as a parameter to the `println` method where it is displayed on the computer screen.

Multiply by a literal double value

The arithmetic expression uses the multiplication operator (*) to multiply the value stored in `myIntVar` by 2.0 (*this literal operand is type `double` by default*).

Automatic conversion to wider type

When arithmetic is performed using operands of different types, the type of the operand of the narrower type is automatically converted to the type of the operand of the wider type, and the arithmetic is performed on the basis of the wider type.

Result is of the wider type

The type of the result is the same as the wider type.

In this case ...

Because the left operand is type `double`, the `int` value is converted to type `double` and the arithmetic is performed as type `double`.

This produces a result of type `double`, causing the floating value 4.294967294E9 to be displayed on the computer screen.

Back to Question 5 (p. 2340)

7.3.7.12 Answer 4

C. 2147483647

7.3.7.12.1 Explanation 4**Uses a cast operator**

This program, named `Ap013.java`, differs from the earlier program named `Ap012.java` in one important respect.

This program uses a *cast operator* to force the compiler to allow a narrowing conversion in order to assign a `double` value to an `int` variable.

The cast operator

The statement containing the cast operator is shown below for convenient viewing.

```
myIntVar = (int)myDoubleVar;
```

Table 7.45

Syntax of a cast operator

The cast operator consists of the name of a type contained within a pair of matching parentheses.

A unary operator

The cast operator always appears to the left of an expression whose type is being converted to the type specified by the cast operator.

Assuming responsibility for potential problems

When dealing with primitive types, the cast operator is used to notify the compiler that the programmer is willing to assume the risk of a possible loss of precision in a narrowing conversion.

No loss of precision here

In this case, there was no loss in precision, but that was only because the value stored in the `double` variable was within the allowable value range for an `int`.

In fact, it was the largest positive value that can be stored in the type `int`. Had it been any larger, a loss of precision would have occurred.

More on this later ...

I will have quite a bit more to say about the cast operator in future modules. I will also have more to say about the use of the assignment operator in conjunction with the non-primitive types.

Back to Question 4 (p. 2339)

7.3.7.13 Answer 3

A. Compiler Error

7.3.7.13.1 Explanation 3

Conversion from double to int is not automatic

This program attempts to assign a value of type `double` to a variable of type `int`.

Even though we know that the specific double value involved would fit in the `int` variable with no loss of precision, the conversion from `double` to `int` is not a *widening* conversion.

This is a narrowing conversion

In fact, it is a *narrowing* conversion because the allowable value range for an `int` is less than the allowable value range for a `double`.

The conversion is not allowed by the compiler. The following compiler error occurs under JDK 1.3:

```

Ap012.java:16: possible loss of precision
found   : double
required: int
    myIntVar = myDoubleVar    myIntVar = myDoubleVar;

```

Table 7.46

Back to Question 3 (p. 2338)

7.3.7.14 Answer 2

C. 2.147483647E9

7.3.7.14.1 Explanation 2

Declare a double

The method named `doAsg` first declares a local variable of type `double` named `myDoubleVar` without providing an initial value.

Declare and initialize an int

Then it declares an `int` variable named `myIntVar` and initializes its value to the integer value 2147483647 (*you learned about `Integer.MAX_VALUE` in an earlier module*).

Assign the int to the double

Following this, the method assigns contents of the `int` variable to the `double` variable.

An assignment compatible conversion

This is an *assignment compatible* conversion. In particular, the integer value of 2147483647 is automatically converted to a `double` value and stored in the `double` variable.

The `double` representation of that value is what appears on the screen later when the value of `myDoubleVar` is displayed.

What is an assignment compatible conversion?

An assignment compatible conversion for the primitive types occurs when the required conversion is a *widening* conversion.

What is a widening conversion?

A widening conversion occurs when the allowable value range of the type of the left operand of the assignment operator is greater than the allowable value range of the right operand of the assignment operator.

A double is wider than an int

Since the allowable value range of type **double** is greater than the allowable value range of type **int**, assignment of an **int** value to a **double** variable is allowed, with conversion from **int** to **double** occurring automatically.

A safe conversion

It is also significant to note that there is no loss in precision when converting from an **int** to a **double**.

An unsafe but allowable conversion

However, a loss of precision may occur when an **int** is assigned to a **float**, or when a **long** is assigned to a **double**.

What would a float produce ?

The value of 2.14748365E9 shown for selection D is what you would see for this program if you were to change the **double** variable to a **float** variable. (*Contrast this with 2147483647 to see the loss of precision.*)

Widening is no guarantee that precision will be preserved

The fact that a type conversion is a widening conversion does not guarantee that there will be no loss of precision in the conversion. It simply guarantees that the conversion will be allowed by the compiler. In some cases, such as that shown above (p. 2363), an assignment compatible conversion can result in a loss of precision, so you always need to be aware of what you are doing.

Back to Question 2 (p. 2337)

7.3.7.15 Answer 1

E. 7.0

7.3.7.15.1 Explanation 1

Declare but don't initialize a double variable

The method named **doAsg** begins by declaring a **double** variable named **myVar** without initializing it.

Use the simple assignment operator

The simple assignment operator (=) is then used to assign the **double** value 3.0 to the variable. Following the execution of that statement, the variable contains the value 3.0.

Use the arithmetic/assignment operator

The next statement uses the combined arithmetic/assignment operator (+=) to add the value 4.0 to the value of 3.0 previously assigned to the variable. The following two statements are functionally equivalent:

```
myVar += 4.0;

myVar = myVar + 4.0;
```

Table 7.47

Two statements are equivalent

This program uses the first statement listed above. If you were to replace the first statement with the second statement, the result would be the same.

In this case, either statement would add the value 4.0 to the value of 3.0 that was previously assigned to the variable named `myVar`, producing the sum of 7.0. Then it would assign the sum of 7.0 back to the variable. When the contents of the variable are then displayed, the result is that 7.0 appears on the computer screen.

No particular benefit

To the knowledge of this author, there is no particular benefit to using the combined arithmetic/assignment notation other than to reduce the amount of typing required to produce the source code. However, if you ever plan to interview for a job as a Java programmer, you need to know how to use the combined version.

Four other similar operators

Java support several combined operators. Some involve arithmetic and some involve other operations such as bit shifting. Five of the combined operators are shown below. These five all involve arithmetic.

- +=
- -=
- *=
- /=
- %=

In all five cases, you can construct a functionally equivalent arithmetic and assignment statement in the same way that I constructed the functionally equivalent statement for += above.

7.4.2 Preface

This module is part of a self-assessment test designed to help you determine how much you know about object-oriented programming using Java.

The test consists of a series of questions with answers and explanations of the answers.

The questions and the answers are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back.

I recommend that you open another copy of this document in a separate browser window and use the links to under Listings (p. 2380) to easily find and view the listings while you are reading about them.

7.4.3 Questions

7.4.3.1 Question 1 .

Given: The use of **String** concatenation in the argument list of the call to the **println** method in the program shown in Listing 1 (p. 2365) will cause seven items to be displayed on the screen, separated by spaces.

True or False? The program produces the output shown below:

```
false true false false true true false
```

Table 7.48

Listing 1 . Listing for Question 1.

```
public class Ap025{
public static void main(
                    String args[]){
    new Worker().doRelat();
} //end main()
} //end class definition

class Worker{
public void doRelat(){
    int a = 1, b = 2, c = 3, d = 2;

    System.out.println(
        (a == b) + " " +
        (b == d) + " " +
        (b != d) + " " +
        (c < a) + " " +
        (b <= d) + " " +
        (c > d) + " " +
        (a >= c));
} //end doRelat()
} //end class definition
```

7.4.6 Answers

7.4.6.1 Answer 15

C. 0 1 2 3 3

7.4.6.1.1 Explanation 15

No return statement is required

A method with a signature that specifies a **void** return type does not require a **return** statement.

However, such a method may contain a **return** statement, provided that it is terminated immediately with a semicolon (*no expression between the word return and the semicolon*) .

(*Every method whose return type is not void must contain at least one return statement.*)

Multiple return statements are allowed

Any method may contain any number of **return** statements provided that they make sense from a syntax viewpoint, and provided the expression (*or lack thereof*) between the word **return** and the semicolon evaluates to the type specified in the method signature (*or a type that will be automatically converted to the type specified in the method signature*) .

A return statement terminates a method immediately

Whenever the execution stream encounters any **return** statement, the method is terminated immediately, and control is returned to the method that called that method.

Back to Question 15 (p. 2379)

7.4.6.2 Answer 14

A. Compiler Error

7.4.6.2.1 Explanation 14

Missing return statement

This program produces the following compiler error under JDK 1.3:

```
Ap037.java:11: missing return statement
public int doLoop(){
```

Table 7.64

Even though this program contains a **return** statement inside the **for** loop, it is still necessary to place a **return** statement at the end of the method to satisfy the compiler. (*The one shown in the code is a comment.*)

The method named **doLoop** must return a value of type **double**. Apparently the compiler assumes that the **return** statement inside the **for** loop may never be executed (*although that isn't true in this case*).

Both of the **return** statements must return a value that satisfies the **double** type requirement given in the method signature.

Returning a value of type **int** in the **for** loop will satisfy the type requirement because type **int** will be automatically converted to type **double** as it is returned. (*Conversion from type **int** to type **double** is a widening conversion.*)

Back to Question 14 (p. 2378)

7.4.6.3 Answer 13

A. Compiler Error

7.4.6.3.1 Explanation 13

The scope of a local variable

In general, the scope of a local variable extends from the point at which it is declared to the curly brace that signals the end of the block in which it is declared.

This applies to for loop in an interesting way

While it is allowable to declare a variable within the first clause of a **for** loop, the scope of that variable is limited to the block of code contained in the loop structure.

The variable cannot be accessed outside the loop.

Attempts to access variable out of scope

This program attempts to access the value of the variable named **cnt** after the loop terminates.

The program displays the following compiler error under JDK 1.3. This error results from the attempt to display the value of the counter after the loop terminates.

```
Ap037.java:15: cannot resolve symbol
symbol  : variable cnt
location: class Worker
    System.out.println(cnt + " ");
```

Table 7.65

Back to Question 13 (p. 2377)

7.4.6.4 Answer 12

C. 0 1 2 3 4 5

7.4.6.4.1 Explanation 12

A simple for loop structure

This program illustrates a simple **for** loop that displays the value of its counter using a call to the **print** method inside the loop.

After the loop terminates, the program displays the value of the counter one last time using a call to **println**.

Three clauses separated by semicolons

The first line of a **for** loop structure always contains three clauses separated by semicolons.

The first and third clauses may be empty, but the semicolons are required in any case.

The first clause ...

The first clause is executed once and only once at the beginning of the loop.

It can contain just about any valid Java expression.

It can even contain more than one expression with the individual expression separated by commas.

When the first clause contains more than one expression separated by commas, the expressions are evaluated in left-to-right order.

The second clause

The second clause is a conditional clause. It must contain an expression that returns a **boolean** value.

(Actually, this clause can also be empty, in which case it is apparently assumed to be true. This leads to an infinite loop unless there is some code inside the loop to terminate it, perhaps by executing a return or a break statement.)

An entry-condition loop

The **for** loop is an entry condition loop, meaning that the conditional expression is evaluated once immediately after the first clause is executed, and once per iteration thereafter.

Behavior of the for loop

If the conditional expression returns true, the block of code following the closing parenthesis is executed.

If it returns false, the block of code is skipped, and control passes to the first executable statement following the block of code.

(For the case where the block contains only one statement, the matching curly brackets can be omitted.)

The third clause

The third clause can contain none, one, or more valid expressions separated by commas.

If there are more than one, they are evaluated in left-to-right order.

When they are evaluated

The expressions in the third clause are evaluated once during each iteration.

However, it is very important to remember that despite the physical placement of the clause in the first line, the expressions in the third clause are not evaluated until after the code in the block has been evaluated.

Typically an update clause

The third clause is typically used to update a counter, but this is not a technical requirement.

This clause can be used for just about any purpose.

However, the counter must be updated somewhere within the block of code or the loop will never terminate.

*(Stated differently, something must occur within the block of code to eventually cause the conditional expression to evaluate to false. Otherwise, the loop will never terminate on its own. However, it is possible to execute a **return** or **break** within the block to terminate the loop.)*

Note the first output value for this program

Because the update in the third clause is not executed until after the code in the block has been executed, the first value displayed (p. 2383) by this program is the value zero.

Back to Question 12 (p. 2376)

7.4.6.5 Answer 11

E. None of the above

7.4.6.5.1 Explanation 11**And the answer is ...**

The output produced by this program is:

1 3 5

A simple while loop

This program uses a simple **while** loop to display the value of a counter, once during each iteration.

Behavior of a while loop

As long as the relational expression in the conditional clause returns true, the block of code immediately following the conditional clause is executed.

When the relational expression returns false, the block of code following the conditional clause is skipped and control passes to the next executable statement following that block of code.

An entry-condition loop

The **while** loop is an entry condition loop, meaning that the test is performed once during each iteration before the block of code is executed.

If the first test returns false, the block of code is skipped entirely.

An exit-condition loop

There is another loop, known as a **do-while** loop, that performs the test after the block of code has been executed once. This guarantees that the block of code will always be executed at least once.

Just to make things interesting ...

Two statements using the increment operator were placed inside the loop in this program.

Therefore, insofar as the conditional test is concerned, the counter is being incremented by twos. This causes the output to display the sequence 1 3 5.

Nested while loops

The **while** loop control structure can contain loops nested inside of loops, which leads to some interesting behavior.

Back to Question 11 (p. 2375)

7.4.6.6 Answer 10

F. $x \neq 4,5,6$

7.4.6.6.1 Explanation 10**A multiple-choice structure**

This is a form of control structure that is often used to make logical decisions in a *multiple-choice* sense.

This is a completely general control structure. It can be used with just about any type of data.

A switch structure

There is a somewhat more specialized, control structure named **switch** that can also be used to make decisions in a multiple choice sense under certain fairly restrictive conditions.

However, the structure shown in this program can always be used to replace a switch. Therefore, I find that I rarely use the **switch** structure, opting instead for the more general form of multiple-choice structure.

Back to Question 10 (p. 2374)

7.4.6.7 Answer 9

D. Goodbye World

7.4.6.7.1 Explanation 9

An if-else control structure

This program contains a simple **if-else** control structure.

Behavior of if-else structure

If the expression in the conditional clause returns true, the block of code following the conditional clause is executed, and the block of code following the word **else** is skipped.

If the expression in the conditional clause returns false, the block of code following the conditional clause is skipped, and the block of code following the word **else** is executed.

This program executes the else block

In this program, the expression in the conditional clause returns false.

Therefore, the block of code following the word **else** is executed, producing the words *Goodbye World* on the computer screen.

Can result in very complex structures

While the structure used in this program is relatively simple, it is possible to create very complex control structures by nesting additional **if-else** structures inside the blocks of code.

Back to Question 9 (p. 2373)

7.4.6.8 Answer 8

D. Hello World

7.4.6.8.1 Explanation 8

A simple if statement

This program contains a simple **if** statement that

- uses a relational expression
- to return a value of type **boolean** inside its conditional clause

Tests for x less than y

The relational expression tests to determine if the value of the variable named **x** is less than the value of the variable named **y** .

Since the value of **x** is 5 and the value of **y** is 6, this relational expression returns true.

Behavior of an if statement

If the expression in the conditional clause returns true, the block of code following the conditional clause is executed

What is a block of code?

A block of code is one or more statements surrounded by matching curly brackets.

For cases like this one where the block includes only one statement, the curly brackets can be omitted. However, I prefer to put them there anyway. They don't cause any harm and help me avoid programming errors if I come back later and add more statements to the body of the **if** statement.

Display the word Hello

In this program, execution of the code in the block causes the **print** method to be called and the word *Hello* to be displayed followed by a space, but without a newline following the space.

What if the conditional clause returns false?

If the expression in the conditional clause returns false, the block of code following the conditional clause is bypassed.

(That is not the case in this program.)

After the if statement ...

After the **if** statement is executed in this program, the **println** method is called to cause the word *World* to be displayed on the same line as the word *Hello* .

Back to Question 8 (p. 2372)

7.4.6.9 Answer 7

A. Compiler Error

7.4.6.9.1 Explanation 7**Not the same as C and C++**

Unlike C and C++, which can use an integer numeric expression in the conditional clause of an `if` statement, Java requires the conditional clause of an `if` statement to contain an expression that will return a **boolean** result.

Bad conditional expression

That is not the case in this program, and the following compiler error occurs under JDK 1.3:

```
Ap031.java:13: incompatible types
found   : int
required: boolean
    if(x - y){
```

Table 7.66

Back to Question 7 (p. 2371)

7.4.6.10 Answer 6

D. 6 4 9.3 7.3000000000000001

7.4.6.10.1 Explanation 6**Postfix increment and decrement operators**

This program illustrates the use of the increment (`++`) and decrement (`--`) operators in their postfix form.

Behavior of increment operator

Given a variable `x`, the following two statements are equivalent:

```
    x++;
x = x + 1;
```

Table 7.67**Behavior of decrement operator**

Also, the following two statements are equivalent:

```
    x--;
x = x - 1;
```

Table 7.68

Prefix and postfix forms available

These operators have both a prefix form and a postfix form.

Can be fairly complex

It is possible to construct some fairly complex scenarios when using these operators and combining them into expressions.

In these modules ...

In this group of self-assessment modules, the increment and decrement operators will primarily be used to update control variables in loops.

Inaccurate results

Regarding the program output, you will note that there is a little arithmetic inaccuracy when this program is executed using JDK 1.3. (*The same is still true with JDK version 1.7.*)

Ideally, the output value 7.300000000000001 should simply be 7.3 without the very small additional fractional part, but that sort of thing often happens when using floating types.

Back to Question 6 (p. 2370)

7.4.6.11 Answer 5

A. Compiler Error

7.4.6.11.1 Explanation 5

Cannot use > with reference variables

The only relational operator that can be applied to reference variables is the == operator.

As discussed in the previous questions, even then it can only be used to determine if two reference variables refer to the same object.

This program produces the following compiler error under JDK 1.3:

```
Ap029.java:14: operator > cannot be applied to Dummy,Dummy
    System.out.println(x > y);
```

Table 7.69

Back to Question 5 (p. 2369)

7.4.6.12 Answer 4

E. true true

7.4.6.12.1 Explanation 4

Two references to the same object

In this case, the reference variables named `x` and `y` both refer to the same object. Therefore, when tested for equality, using either the == operator or the default `equals` method, the result is true.

Back to Question 4 (p. 2368)

7.4.6.13 Answer 3

D. false

7.4.6.13.1 Explanation 3**Read question 2**

In case you skipped it, you need to read the explanation for the answer to Question 2 (p. 2365) before reading this explanation.

Objects appear to be equal

These two objects are of the same type and contain the same values. Why are they reported as not being equal?

Did not override the equals method

When I defined the class named **Dummy** used in the programs for Question 2 (p. 2365) and Question 3 (p. 2367), I did not override the method named **equals**.

Therefore, my class named **Dummy** simply inherited the default version of the method named **equals** that is defined in the class named **Object**.

Default behavior of equals method

The default version of the **equals** method behaves essentially the same as the `==` operator.

That is to say, the inherited default version of the **equals** method will return true if the two objects being compared are actually the same object, and will return false otherwise.

As a result, this program displays false.

Overridden equals is required for valid testing

If you want to be able to determine if two objects instantiated from a class that you define are "equal", you must override the inherited **equals** method for your new class. You cannot depend on the inherited version of the **equals** method to do that job for you.

Overriding may not be easy

That is not to say that overriding the **equals** method is easy. In fact, it may be quite difficult in those cases where the class declares instance variables that refer to other objects. In this case, it may be necessary to test an entire tree of objects for equality.

Back to Question 3 (p. 2367)

7.4.6.14 Answer 2

D. false

7.4.6.14.1 Explanation 2**Use of the `==` operator with references to objects**

This program illustrates an extremely important point about the use of the `==` operator with objects and reference variables containing references to objects.

You cannot determine...

You cannot determine if two objects are "equal" by applying the `==` operator to the reference variables containing references to those objects.

Rather, that test simply determines if two reference variables refer to the same object.

Two references to the same object

Obviously, if there is only one object, referred to by two different reference variables, then it is "equal" to itself.

Objects of same type containing same instance values

On the other hand, two objects of the same type could contain exactly the same data values, but this test would not indicate that they are "equal." (*In fact, that is the case in this program.*)

So, how do you test two objects for equal?

In order to determine if two objects are "equal", you must devise a way to compare the types of the two objects and actually compare the contents of one object to the contents of the other object. Fortunately, there is a standard framework for doing this.

The equals method

In particular, the class named **Object** defines a default version of a method named **equals** that is inherited by all other classes.

Class author can override the equals method

The intent is that the author of a new class can override the **equals** method so that it can be called to determine if two objects instantiated from that class are "equal."

What does "equal" mean for objects?

Actually, that is up to the author of the class to decide.

After having made that decision, the author of the class writes that behavior into her overridden version of the method named **equals**.

Back to Question 2 (p. 2365)

7.4.6.15 Answer 1

The answer is True.

7.4.6.15.1 Explanation 1

Not much to explain here

There isn't much in the way of an explanation to provide for this program.

Evaluate seven relational expressions

Each of the seven relational expressions in the argument list for the **println** method is evaluated and returns either true or false as a **boolean** value.

Concatenate the individual results, separated by a space

The seven **boolean** results are concatenated, separated by space characters, and displayed on the computer screen.

Brief description of the relational operators

Just in case you aren't familiar with the relational operators, here is a brief description.

Each of these operators returns the **boolean** value true if the specified condition is met. Otherwise, it returns false.

<pre> == Left operand equals the right operand != Left operand is not equal to the right operand < Left operand is less than the right operand <= Left operand is less than or equal to the right operand > Left operand is greater than the right operand >= Left operand is greater than or equal to the right operand </pre>

7.5.2 Preface

This module is part of a self-assessment test designed to help you determine how much you know about object-oriented programming using Java.

The test consists of a series of questions with answers and explanations of the answers.

The questions and the answers are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back.

I recommend that you open another copy of this document in a separate browser window and use the links to under Listings (p. 2400) to easily find and view the listings while you are reading about them.

7.5.3 Questions

7.5.3.1 Question 1 .

What output is produced by the program shown in Listing 1 (p. 2391) ?

- A. Compiler Error
- B. Runtime Error
- C. A
- D. B
- E. None of the above

¹³This content is available online at <<http://cnx.org/content/m45260/1.6/>>.

7.5.6 Answers

7.5.6.1 Answer 10

C. Sun Dec 02 17:35:00 CST 2012 1354491300781

7.5.6.1.1 Explanation 10

The noarg constructor for the Date class

The **Date** class has a constructor that takes no parameters and is described in the documentation as follows:

*"Allocates a **Date** object and initializes it so that it represents the time at which it was allocated, measured to the nearest millisecond."*

In other words, this constructor can be used to instantiate a **Date** object that represents the current date and time according to the system clock.

A property named time of type long

The actual date and time information encapsulated in a **Date** object is apparently stored in a property named **time** as a **long** integer.

Milliseconds since the epoch

The **long** integer encapsulated in a **Date** object represents the total number of milliseconds for the encapsulated date and time, relative to the epoch, which was Jan 01 00:00:00 GMT 1970.

Earlier dates are represented as negative values. Later dates are represented as positive values.

An overridden toString method

An object of the **Date** class has an overridden **toString** method that converts the value in milliseconds to a form that is more useful for a human observer, such as:

Sun Dec 02 17:35:00 CST 2012

Instantiate a Date object with the noarg constructor

This program instantiates an object of the **Date** class using the constructor that takes no parameters.

Call the overridden toString method

Then it calls the overridden **toString** method to populate a **String** object that represents the **Date** object.

Following this, it displays that **String** object by calling the **print** method, producing the first part of the output shown above. (*The actual date and time will vary depending on when the program is executed.*)

Get the time property value

Then it calls the `getTime` method to get and display the value of the `time` property.
This is a representation of the same date and time shown above (p. 2401) , but in milliseconds:

1354491300781

Back to Question 10 (p. 2399)

7.5.6.2 Answer 9

D. Joe Age = 35 Weight = 162.5

7.5.6.2.1 Explanation 9

Upgraded program from Question 8

The program used for this question is an upgrade to the program that was used for Question 8 (p. 2397)

Dummy class overrides the toString method

In particular, in this program, the class named `Dummy` overrides the `toString` method in such a way as to return a `String` representing the object that would be useful to a human observer.

The `String` that is returned contains the values of the instance variables of the object: name, age, and weight.

Overridden toString method code

The overridden `toString` method for the `Dummy` class is shown below for easy reference.

Overridden `toString` method

```
public String toString(){
String x = name + " " +
        " Age = " + age + " " +
        " Weight = " + weight;
return x;
} //end toString()
```

Table 7.81

The code in the overridden `toString` method is almost trivial.

The important thing is not the specific code in a specific overridden version of the `toString` method.

Why override the toString method?

Rather, the important thing is to understand why you should probably override the `toString` method in most of the new classes that you define.

In fact, you should override the `toString` method in all new classes that you define if a `String` representation of an instance of that class will ever be needed for any purpose.

The code will vary

The code required to override the `toString` method will vary from one class to another. The important point is that the code must return a reference to a `String` object. The `String` object should encapsulate information that represents the original object in a format that is meaningful to a human observer.

Back to Question 9 (p. 2398)

7.5.6.3 Answer 8

C. Dummy@273d3c

7.5.6.3.1 Explanation 8

Display an object of the Dummy class

This program instantiates a new object of the `Dummy` class, and passes that object's reference to the method named `println`.

The purpose of the `println` method is to display a representation of the new object that is meaningful to a human observer. In order to do so, it requires a `String` representation of the object.

The toString method

The class named `Object` defines a default version of a method named `toString`.

All classes inherit the `toString` method.

A child of the Object class

Those classes that extend directly from the class named `Object` inherit the default version of the `toString` method.

Grandchildren of the Object class

Those classes that don't directly extend the class named `Object` also inherit a version of the `toString` method.

May be default or overridden version

The inherited `toString` method may be the default version, or it may be an overridden version, depending on whether the method has been overridden in a superclass of the new class.

The purpose of the toString method

The purpose of the `toString` method defined in the `Object` class is to be overridden in new classes.

The body of the overridden version should return a reference to a `String` object that represents an object of the new class.

Whenever a String representation of an object is required

Whenever a `String` representation of an object is required for any purpose in Java, the `toString` method is called on a reference to the object.

The `String` that is returned by the `toString` method is taken to be a `String` that represents the object.

When toString has not been overridden

When the `toString` method is called on a reference to an object for which the method has not been overridden, the default version of the method is called.

The default `String` representation of an object

The `String` returned by the default version consists of the following:

- The name of the class from which the object was instantiated
- The @ character
- A hexadecimal value that is the `hashCode` value for the object

As you can see, this does not include any information about the values of the data stored in the object.

Other than the name of the class from which the object was instantiated, this is not particularly useful to a human observer.

Dummy class does not override toString method

In this program, the class named `Dummy` extends the `Object` class directly, and doesn't override the `toString` method.

Therefore, when the `toString` method is called on a reference to an object of the `Dummy` class, the `String` that is returned looks something like the following:

```
Dummy@273d3c
```

Note that the six hexadecimal digits at the end will probably be different from one program to the next.

Back to Question 8 (p. 2397)

7.5.6.4 Answer 7

C. 3.5/9/true

7.5.6.4.1 Explanation 7

More on String concatenation

This program illustrates **String** concatenation.

The plus (+) operator is what is commonly called an *overloaded operator* .

What is an overloaded operator?

An overloaded operator is an operator whose behavior depends on the types of its operands.

Plus (+) as a unary operator

The plus operator can be used as either a **unary** operator or a **binary** operator. However, as a unary operator, with only one operand to its right, it doesn't do anything useful. This is illustrated by the following two statements, which are functionally equivalent.

```
x = y;
```

```
x = +y;
```

Plus (+) as a binary operator

As a binary operator, the plus operator requires two operands, one on either side. (*This is called infix notation.*) When used as a binary operator, its behavior depends on the types of its operands.

Two numeric operands

If both operands are numeric operands, the plus operator performs arithmetic addition.

If the two numeric operands are of different types, the narrower operand is converted to the type of the wider operand, and the addition is performed as the wider type.

Two String operands

If both operands are references to objects of type **String** , the plus operator creates and returns a new **String** object that contains the concatenated values of the two operands.

One String operand and one of another type

If one operand is a reference to an object of type **String** and the other operand is of some type other than **String** , the plus operator causes a new **String** object to come into existence.

This new **String** object is a **String** representation of the *non-String* operand (*such as a value of type **int***) ,

Then it concatenates the two **String** objects, producing another new **String** object, which is the concatenation of the two.

How is the new String operand representing the non-string operand created?

The manner in which it creates the new **String** object that represents the non-String operand varies with the actual type of the operand.

A primitive operand

The simplest case is when the non-String operand is one of the primitive types. In these cases, the capability already exists in the core programming language to produce a **String** object that represents the value of the primitive type.

A boolean operand

For example, if the operand is of type **boolean** , the new **String** object that represents the operand will either contain the word true or the word false.

A numeric operand

If the operand is one of the numeric types, the new **String** object will be composed of some of the following:

- numeric characters
- a decimal point character
- minus characters
- plus character
- other characters such as E or e

These characters will be arranged in such a way as to represent the numeric value of the operand to a human observer.

In this program ...

In this program, a numeric **double** value, a numeric **int** value, and a **boolean** value were concatenated with a pair of slash characters to produce a **String** object containing the following:

3.5/9/true

When a reference to this **String** object was passed as a parameter to the **println** method, the code in that method extracted the character string from the **String** object, and displayed that character string on the screen.

The toString method

If one of the operands to the plus operator is a reference to an object, the **toString** method is called on the reference to produce a string that represents the object. The **toString** method may be overridden by the author of the class from which the object was instantiated to produce a **String** that faithfully represents the object.

Back to Question 7 (p. 2396)

7.5.6.5 Answer 6

C. 4 -3

7.5.6.5.1 Explanation 6**A rounding algorithm**

The method named **doIt** in this program illustrates an algorithm that can be used with a numeric cast operator (**int**) to cause **double** values to be rounded to the nearest integer.

Different than truncation toward zero

Note that this is different from simply truncating to the next integer closer to zero (*as was illustrated in Question 5 (p. 2394)*).

Back to Question 6 (p. 2395)

7.5.6.6 Answer 5

D. 3 -3

7.5.6.6.1 Explanation 5**Truncates toward zero**

When a **double** value is cast to an **int**, the fractional part of the **double** value is discarded.

This produces a result that is the next integer value closer to zero.

This is true regardless of whether the **double** is positive or negative. This is sometimes referred to as its *"truncation toward zero"* behavior.

Not the same as rounding

If each of the values assigned to the variables named **w** and **x** in this program were rounded to the nearest integer, the result would be 4 and -4, not 3 and -3 as produced by the program.

Back to Question 5 (p. 2394)

7.5.6.7 Answer 4

A. Compiler Error

7.5.6.7.1 Explanation 4**Cannot cast a boolean type**

A **boolean** type cannot be cast to any other type. This program produces the following compiler error:

```

Ap042.java:13: inconvertible types
found   : boolean
required: int
    int y = (int)x;

```

Table 7.82

Back to Question 4 (p. 2393)

7.5.6.8 Answer 3

D. B

7.5.6.8.1 Explanation 3

The logical and operator

The logical and operator shown below

The *logical and* operator

&&

Table 7.83

performs an **and** operation between its two operands, both of which must be of type **boolean** . If both operands are true, the operator returns true. Otherwise, it returns false.

The boolean negation operator

The boolean negation operator shown below

The *boolean negation* operator !

Table 7.84

is a *unary* operator, meaning that it always has only one operand. That operand must be of type **boolean** , and the operand always appears immediately to the right of the operator.

The behavior of this operator is to change its right operand from true to false, or from false to true.

Evaluation from left to right

Now, consider the following code fragment from this program.

```

    int x = 5, y = 6;
    if(!(x < y) && !(y < x/0)){
        System.out.println("A");
    }else{
        System.out.println("B");
    }//end else

```

Table 7.85

The individual operands of the *logical and* operator are evaluated from left to right. Consider the left operand of the *logical and* operator that reads:

```
!(x<y)
```

Table 7.86

The following expression is true

```
(x < y)
```

Table 7.87

In this case, **x** is less than **y**, so the expression inside the parentheses evaluates to true.

The following expression is false

```
!(x < y)
```

Table 7.88

The true result becomes the right operand for the *boolean negation* operator at this point.

You might think of the state of the evaluation process at this point as being something like

not true .

When the **!** operator is applied to the **true** result, the combination of the two become a **false** result.

Short-circuit evaluation applies

This, in turn, causes the left operand of the *logical and* operator to be **false** .

At that point, the final outcome of the logical expression has been determined. It doesn't matter whether the right operand is true or false. The final result will be false regardless.

No attempt is made to evaluate the right operand

Therefore, no attempt is made to evaluate the right operand of the *logical and* operator in this case.

No attempt is made to divide the integer variable **x** by zero, no exception is thrown, and the program doesn't terminate abnormally. It runs to completion and displays a B on the screen.

Back to Question 3 (p. 2392)

7.5.6.9 Answer 2

C. A

7.5.6.9.1 Explanation 2**Short-circuit evaluation**

Question 1 (p. 2390) was intended to set the stage for this question.

This Question, in combination with Question 1 (p. 2390) , is intended to help you understand and remember the concept of short-circuit evaluation.

What is short-circuit evaluation?

Logical expressions are evaluated from left to right. That is, the left operand of a logical operator is evaluated before the right operand of the same operator is evaluated.

When evaluating a logical expression, the final outcome can often be determined without the requirement to evaluate all of the operands.

Once the final outcome is determined, no attempt is made to evaluate the remainder of the expression. This is short-circuit evaluation.

Code from Question 1

Consider the following code fragment from Question 1 (p. 2390) :

```
int x = 5, y = 6;
if((x > y) || (y < x/0)){
    ...
}
```

Table 7.89

The (||) operator is the *logical or* operator.

Boolean operands required

This operator requires that its left and right operands both be of type **boolean** . This operator performs an *inclusive or* on its left and right operands. The rules for an inclusive or are:

If either of its operands is true, the operator returns true. Otherwise, it returns false.

Left operand is false

In this particular expression, the value of **x** is not greater than the value of **y** . Therefore, the left operand of the *logical or* operator is not true.

Right operand must be evaluated

This means that the right operand must be evaluated in order to determine the final outcome.

Right operand attempts to divide by zero

However, when an attempt is made to evaluate the right operand, an attempt is made to divide **x** by zero. This throws an exception, which is not caught and handled by the program, so the program terminates as described in Question 1 (p. 2390) .

Similar code from Question 2

Now consider the following code fragment from Question 2 (p. 2391) .

```
int x = 5, y = 6;
if((x < y) || (y < x/0)){
    System.out.println("A");
    ...
}
```

Table 7.90

Note that the right operand of the *logical or* operator still contains an expression that attempts to divide the integer `x` by zero.

No runtime error in this case

This program does not terminate with a runtime error. Why not?

And the answer is ...

In this case, `x` is less than `y`. Therefore, the left operand of the *logical or* operator is true.

Remember the rule for inclusive or

It doesn't matter whether the right operand is true or false. The final outcome is determined as soon as it is determined that the left operand is true.

The bottom line

Because the final outcome has been determined as soon as it is determined that the left operand is true, no attempt is made to evaluate the right operand.

Therefore, no attempt is made to divide `x` by zero, and no runtime error occurs.

Short-circuit evaluation

This behavior is often referred to as *short-circuit evaluation*.

Only as much of a logical expression is evaluated as is required to determine the final outcome.

Once the final outcome is determined, no attempt is made to evaluate the remainder of the logical expression.

This is not only true for the *logical or* operator, it is also true for the *logical and* operator, which consists of two ampersand characters with no space between them.

Back to Question 2 (p. 2391)

7.5.6.10 Answer 1

B. Runtime Error

7.5.6.10.1 Explanation 1

Divide by zero

Whenever a Java program attempts to evaluate an expression requiring that a value of one of the integer types be divided by zero, it will throw an **ArithmeticException**. If this exception is not caught and handled by the program, it will cause the program to terminate.

Attempts to divide `x` by 0

This program attempts to evaluate the following expression:

`(y < x/0)`

Table 7.91

This expression attempts to divide the variable named `x` by zero. This causes the program to terminate with the following error message when running under JDK 1.3:

```

java.lang.ArithmeticException: / by zero
at Worker.doLogical(Ap039.java:13)
at Ap039.main(Ap039.java:6)

```

7.6.2 Preface

This module is part of a self-assessment test designed to help you determine how much you know about object-oriented programming using Java.

The test consists of a series of questions with answers and explanations of the answers.

The questions and the answers are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back.

I recommend that you open another copy of this document in a separate browser window and use the links to under Listings (p. 2425) to easily find and view the listings while you are reading about them.

7.6.3 Questions

7.6.3.1 Question 1 .

What output is produced by the program shown in Listing 1 (p. 2411) ?

- A. Compiler Error
- B. Runtime Error
- C. \ "Backslash\ "->\\\nUnderstand
- D. "Backslash"->\nUnderstand

class Worker{
    public void doArrays(){
        int A[][] = new int[3][];
        A[0] = new int[1];
        A[1] = new int[2];
        A[2] = new int[3];

        for(int i = 0;i < A.length;i++){
            for(int j=0;j < A[i].length;j++){
                A[i][j] = i*j;
            }//end inner for loop
        }//end outer for loop

        for(int i=0;i<A.length;i++){
            for(int j=0;j < A[i].length;j++){
                System.out.print(
                    A[i][j] + " ");
            }//end inner for loop
            System.out.println("");
        }//end outer for loop

    }//end doArrays()
}// end class

7.6.3.11 Question 11

What output is produced by the program shown in Listing 11 (p. 2421) ?

- A. Compiler Error
- B. Runtime Error
- C. Zero One Two
- D. None of the above

Listing 11 . Listing for Question 11.

```
public class Ap059{
public static void main(
    String args[]){
    new Worker().doArrays();
} //end main()
} //end class definition

class Worker{
public void doArrays(){
    Object[] A = new Object[3];
    //Note that there is a simpler and
    // better way to do the following
    // but it won't illustrate my point
    // as well as doing it this way.
    A[0] = new String("Zero");
    A[1] = new String("One");
    A[2] = new String("Two");

    System.out.println(A[0] + " " +
        A[1] + " " +
        A[2]);
} //end doArrays()
} // end class
```

7.6.6 Answers

7.6.6.1 Answer 15

C. 1.0 2.0

7.6.6.1.1 Explanation 15

This is an upgrade of the program from Question 14 (p. 2423) . This program applies the proper downcast operator to the references extracted from the array of type **Object** before attempting to call the method named **getData** on those references. (*For more information, see the discussion of Question 14 (p. 2423) .*)

As a result of applying a proper downcast, the program compiles and runs successfully.

Back to Question 15 (p. 2424)

7.6.6.2 Answer 14

A. Compiler Error

7.6.6.2.1 Explanation 14**Storing references in a generic array of type `Object`**

This program stores references to two objects instantiated from a new class named `MyClass` in the elements of an array object of declared type `Object` . That is OK.

Calling a method on the references

Then the program extracts the references to the two objects and attempts to call the method named `getData` on each of the references. That is not OK.

Downcast is required

Because the method named `getData` is not defined in the class named `Object` , in order to call this method on references extracted from an array of type `Object` , it is necessary to downcast the references to the class in which the method is defined. In this case, the method is defined in the new class named `MyClass` (but it could be defined in an intermediate class in the class hierarchy if the new class extended some class further down the hierarchy) .

Here is a partial listing of the compiler error produced by this program:

```
Ap062.java:15: error: cannot find symbol
    A[0].getData() + " " +
           ^
symbol:   method getData()
location: class Object
```

Back to Question 14 (p. 2423)

7.6.6.3 Answer 13

D. None of the above.

7.6.6.3.1 Explanation 13

The array object of type `Object` in this program is capable of storing a reference to a new object instantiated from the new class named `MyClass` . However, because the new class does not override the `toString` method, when a string representation of the new object is displayed, the string representation is created using the version of the `toString` method that is inherited from the `Object` class. That causes this program to produce an output similar to the following:

```
Zero 1 MyClass@273d3c
```

Back to Question 13 (p. 2422)

7.6.6.4 Answer 12

C. Zero 1 2.0

7.6.6.4.1 Explanation 12**A type-generic array object**

As explained in Question 11 (p. 2420) , an array object of the type `Object` is a generic array that can be used to store references to objects instantiated from any class.

Storing mixed reference types

This program instantiates objects from the classes **String** , **Integer** , and **Double** , and stores those objects' references in the elements of an array of type **Object** . Then the program accesses the references and uses them to display string representations of each of the objects.

Polymorphic behavior applies

Once again, polymorphic behavior involving overridden versions of the **toString** method were involved and it was not necessary to downcast the references to their true type to display string representations of the objects.

Back to Question 12 (p. 2421)

7.6.6.5 Answer 11

C. Zero One Two

7.6.6.5.1 Explanation 11

Storing references to subclass types

When you create an array object for a type defined by a class definition, the elements of the array can be used to store references to objects of that class or any subclass of that class.

A type-generic array object

All classes in Java are subclasses of the class named **Object** . This program creates an array object with the declared type being type **Object** . An array of type **Object** can be used to store references to objects instantiated from any class.

After creating the array object, this program instantiates three objects of the class **String** and stores those object's references in the elements of the array. *(As I pointed out in the comments, there is a simpler and better way to instantiate **String** objects, but it wouldn't illustrate my point as well as doing the way that I did.)*

Sometimes you need to downcast

Although an array of type **Object** can be used to store references to objects of any type *(including mixed types and references to other array objects)* , you will sometimes need to downcast those references back to their true type once you extract them from the array and attempt to use them for some purpose.

Polymorphic behavior applies here

For this case, however, because the **toString** method is defined in the **Object** class and overridden in the **String** class, polymorphic behavior applies and it is not necessary to downcast the references to type **String** in order to be able to convert them to strings and display them.

Back to Question 11 (p. 2420)

7.6.6.6 Answer 10

C. 0
0 1
0 2 4

7.6.6.6.1 Explanation 10

Defer size specification for secondary arrays

It is not necessary to specify the sizes of the secondary arrays when you create a multi-dimensional array in Java. Rather, since the elements in the primary array simply contain references to other array objects *(or null by default)* , you can defer the creation of those secondary array objects until later.

Independent array objects

When you do finally create the secondary arrays, they are essentially independent array objects (*except for the requirement for type commonality among them*) .

Ragged arrays

Each individual secondary array can be of any size, and this leads to the concept of a *ragged array* .
(*On a two-dimensional basis, a ragged array might be thought of as a two-dimensional array where each row can have a different number of columns.*)

This program creates, populates, and displays the contents of such a two-dimensional ragged array. Although this program creates a two-dimensional array that is triangular in shape, even that is not a requirement. The number of elements in each of the secondary arrays need have no relationship to the number of elements in any of the other secondary arrays.

Back to Question 10 (p. 2419)

7.6.6.7 Answer 9

B. Runtime Error

7.6.6.7.1 Explanation 9

NullPointerException

The following code fragment shows that this program attempts to perform an illegal operation on the value accessed from the array object at index 1.

```
Integer[] A = new Integer[2];
A[0] = new Integer(1);
System.out.println(
    A[1].intValue());
```

You can't call methods on null references

The reference value that was returned by accessing **A[1]** is the default value of null. This is the value that was deposited in the element when the array object was created (*no other value was ever stored there*) . When an attempt was made to call the **intValue** method on that reference value, the following runtime error occurred

```
java.lang.NullPointerException
at Worker.doArrays(Ap057.java:14)
at Ap057.main(Ap057.java:6)
```

This is a common programming error, and most Java programmers have seen an error message involving a **NullPointerException** several (**perhaps many**) times during their programming careers.

Back to Question 9 (p. 2418)

7.6.6.8 Answer 8

C. OK

7.6.6.8.1 Explanation 8

Success at last

This program finally gets it all together and works properly. In particular, after accessing the reference values stored in each of the elements, the program does something legal with those values.

Call methods on the object's references

In this case, the code calls one of the public methods belonging to the objects referred to by the reference values stored in the array elements.

```
System.out.println(A[0].getText() + A[1].getText());
```

The `getText` method that is called, returns the contents of the `Label` object as type `String`. This makes it possible to perform `String` concatenation on the values returned by the method, so the program compiles and executes properly.

Back to Question 8 (p. 2417)

7.6.6.9 Answer 7

A. Compiler Error

7.6.6.9.1 Explanation 7

Java arrays may seem different to you

For all types other than the primitive types, you may find the use of arrays in Java to be considerably different from what you are accustomed to in other programming languages. There are a few things that you should remember.

Array elements may contain default values

If the declared type of an array is one of the primitive types, the elements of the array contain values of the declared type. If you have not initialized those elements or have not assigned specific values to the elements, they will contain default values.

The default values

You need to know that:

- The default for numeric primitive types is the zero value for that type
- The default for the `boolean` type is `false`
- The default for the `char` type is a 16-bit unsigned integer, all of whose bits have a zero value (*sometimes called a null character*)
- The default value for reference types is `null`, not to be confused with the *null character* above. (*An array element that contains null doesn't refer to an object.*)

Arrays of references

If the declared type for the array is not one of the primitive types, the elements in the array are actually reference variables. Objects are never stored directly in a Java array. Only references to objects are stored in a Java array.

If the array type is the name of a class ...

If the declared type is the name of a class, references to objects of that class or any subclass of that class can be stored in the elements of the array.

If the array type is the name of an interface ...

If the declared type is the name of an interface, references to objects of any class that implements the interface, or references to objects of any subclass of a class that implements the interface can be stored in the elements of the array.

Why did this program fail to compile?

Now back to the program at hand. Why did this program fail to compile? To begin with, this array was not designed to store any of the primitive types. Rather, this array was designed to store references to objects instantiated from the class named `Label`, as indicated in the following fragment.

```
Label[] A = new Label[2];
```

Elements initialized to null

This is a two-element array. When first created, it contains two elements, each having a default value of `null`. What this really means is that the reference values stored in each of the two elements don't initially refer to any object.

Populate the array elements

The next fragment creates two instances (*objects*) of the `Label` class and assigns those object's references to the two elements in the array object. This is perfectly valid.

```
A[0] = new Label("O");
A[1] = new Label("K");
```

You cannot add reference values

The problem arises in the next fragment. Rather than dealing with the object's references in an appropriate manner, this fragment attempts to access the text values of the two reference variables and concatenate those values.

```
System.out.println(A[0] + A[1]);
```

The compiler produces the following error message:

```
Ap055.java:14: error: bad operand types for binary operator '+'
    System.out.println(A[0] + A[1]);
                        ^
    first type: Label
    second type: Label
1 error
```

This error message is simply telling us that it is not legal to add the values of reference variables.

Not peculiar to arrays

This problem is not peculiar to arrays. You would get a similar error if you attempted to add two reference variables even when they aren't stored in an array. In this case, the code to access the values of the elements is good. The problem arises when we attempt to do something illegal with those values after we access them.

Usually two steps are required

Therefore, except in some special cases such as certain operations involving the wrapper classes, to use Java arrays with types other than the primitive types, when you access the value stored in an element of the array (*a reference variable*) you must perform only those operations on that reference variable that are legal for an object of that type. That usually involves two steps. The first step accesses the reference to an object. The second step performs some operation on the object.

Back to Question 7 (p. 2416)

7.6.6.10 Answer 6

C. 3

7.6.6.10.1 Explanation 6

Once you create an array object for a primitive type in Java, you can treat the elements of the array pretty much as you would treat the elements of an array in other programming languages. In particular, a statement such the following can be used to assign a value to an indexed element in an array referred to by a reference variable named `A`.

```
A[1] = 2;
```

Similarly, when you reference an indexed element in an expression such as the following, the value stored in the element is used to evaluate the expression.

```
System.out.println(A[0] + A[1]);
```

For all Java arrays, you must remember to create the new array object and to store the array object's reference in a reference variable of the correct type. Then you can use the reference variable to gain access to the elements in the array.

Back to Question 6 (p. 2416)

7.6.6.11 Answer 5

B. Runtime Error

7.6.6.11.1 Explanation 5**Good fences make good neighbors**

One of the great things about an array object in Java is that it knows how to protect its boundaries.

Unlike some other currently popular programming languages, if your program code attempts to access a Java array element outside its boundaries, an exception will be thrown. If your program doesn't catch and handle the exception, the program will be terminated.

Abnormal termination

While experiencing abnormal program termination isn't all that great, it is better than the alternative of using arrays whose boundaries aren't protected. Programming languages that don't protect the array boundaries simply overwrite other data in memory whenever the array boundaries are exceeded.

Attempt to access out of bounds element

The code in the `for` loop in the following fragment attempts to access the array element at the index value 5. That index value is out of bounds of the array.

```
    for(int j = 0;j < 6;j++){
System.out.print(
        myArray[i][j] + " ");
} //end inner for loop
```

Because that index value is outside the boundaries of the array, an **ArrayIndexOutOfBoundsException** is thrown. The exception isn't caught and handled by program code, so the program terminates abnormally at runtime.

This program also illustrates that it is usually better to use the **length** property of an array to control iterative loops than to use hard-coded limit values, which may be coded erroneously.

Back to Question 5 (p. 2414)

7.6.6.12 Answer 4

```
C.  1 1 1 1 1
    1 2 3 4 5
    1 3 5 7 9
```

7.6.6.12.1 Explanation 4

A two-dimensional array

This program illustrates how to create, populate, and process a two-dimensional array with three rows and five columns.

(As mentioned earlier, a Java programmer who understands the fine points of the language probably wouldn't call this a two-dimensional array. Rather, this is a one-dimensional array containing three elements. Each of those elements is a reference to a one-dimensional array containing five elements. That is the more general way to think of Java arrays.)

The following code fragment creates the array, using one of the acceptable formats discussed in Question 3 (p. 2412) .

```
int myArray[] [] ;
myArray = new int[3][5];
```

Populating the array

The next code fragment uses a pair of nested **for** loops to populate the elements in the array with values of type **int** .

```
for(int i=0;i<myArray.length;i++){
for(int j=0;
    j<myArray[0].length;j++){
    myArray[i][j] = i*j + 1;
} //end inner for loop
} //end outer for loop
```

This is where the analogy of a two-dimensional array falls apart. It is much easier at this point to think in terms of a three-element primary array, each of whose elements contains a reference to a secondary array containing five elements. *(Note that in Java, the secondary arrays don't all have to be of the same size. Hence, it is possible to create odd-shaped multi-dimensional arrays in Java.)*

Using the length property

Pay special attention to the two chunks of code that use the length properties of the arrays to determine the number of iterations for each of the **for** loops.

The first chunk determines the number of elements in the primary array. In this case, the length property contains the value 3.

The second chunk determines the number of elements in the secondary array that is referred to by the contents of the element at index 0 in the primary array. (*Think carefully about what I just said.*)

In this case, the length property of the secondary array contains the value 5.

Putting data into the secondary array elements

The code interior to the inner loop simply calculates some numeric values and stores those values in the elements of the three secondary array objects.

Let's look at a picture

Here is a picture that attempts to illustrate what is really going on here. I don't know if it will make sense to you or not, but hopefully, it won't make the situation any more confusing than it might already be.

```
[->] [1][1][1][1][1]
```

```
[->] [1][2][3][4][5]
```

```
[->] [1][3][5][7][9]
```

The primary array

The three large boxes on the left represent the individual elements of the three-element primary array. The length property for this array has a value of 3. The arrows in the boxes indicate that the content of each of these three elements is a reference to one of the five-element arrays on the right.

The secondary arrays

Each of the three rows of five boxes on the right represents a separate five-element array object. Each element in each of those array objects contains the `int` value shown. The length property for each of those arrays has a value of 5.

Access and display the array data

The code in the following fragment is another pair of nested `for` loops.

```
for(int i=0;i<myArray.length;i++){
for(int j=0;
    j<myArray[0].length;j++){
    System.out.print(
        myArray[i][j] + " ");
    }//end inner for loop
    System.out.println("");
};//end outer for loop
```

In this case, the code in the inner loop accesses the contents of the individual elements in the three five-element arrays and displays those contents. If you understand the earlier code in this program, you shouldn't have any difficulty understanding the code in this fragment.

Back to Question 4 (p. 2413)

7.6.6.13 Answer 3

A. Compiler Error

7.6.6.13.1 Explanation 3

An incorrect statement

The following statement is not the proper way to create an array object in Java.

```
int myArray[3][5];
```

This statement caused the program to fail to compile, producing several error messages.

What is the correct syntax?

There are several different formats that can be used to create an array object in Java. One of the acceptable ways was illustrated by the code used in Question 2 (p. 2411) . Three more acceptable formats are shown below.

```
int[][] myArrayA = new int[3][5];

int myArrayB[][] = new int[3][5];

int myArrayC[][];
myArrayC = new int[3][5];
```

Two steps are required

The key thing to remember is that an array is an object in Java. Just like all other (*non-anonymous*) objects in Java, there are two steps involved in creating and preparing an object for use.

Declare a reference variable

The first step is to declare a reference variable capable of holding a reference to the object.

The second step

The second step is to create the object and to assign the object's reference to the reference variable. From that point on, the reference variable can be used to gain access to the object.

Two steps can often be combined

Although there are two steps involved, they can often be combined into a single statement, as indicated by the first two acceptable formats shown above.

In both of these formats, the code on the left of the assignment operator declares a reference variable. The code on the right of the assignment operator creates a new array object and returns the array object's reference. The reference is assigned to the new reference variable declared on the left.

A two-dimensional array object

In the code fragments shown above, the array object is a two-dimensional array object that can be thought of as consisting of three rows and five columns.

(Actually, multi-dimensional array objects in Java can be much more complex than this. In fact, although I have referred to this as a two-dimensional array object, there is no such thing as a multi-dimensional array object in Java. The concept of a multi-dimensional array in Java is achieved by creating a tree structure of single-dimensional array objects that contain references to other single-dimensional array objects.)

The square brackets in the declaration

What about the placement and the number of matching pairs of empty square brackets? As indicated in the first two acceptable formats shown above, the empty square brackets can be next to the name of the type or next to the name of the reference variable. The end result is the same, so you can use whichever format you prefer.

How many pairs of square brackets are required?

Also, as implied by the acceptable formats shown above, the number of matching pairs of empty square brackets must match the number of so-called *dimensions* of the array. *(This tells the compiler to create*

a reference variable capable of holding a reference to a one-dimensional array object, whose elements are capable of holding references to other array objects.)

Making the two steps obvious

A third acceptable format, also shown above, separates the process into two steps.

One statement in the third format declares a reference variable capable of holding a reference to a two-dimensional array object containing data of type **int** . When that statement finishes executing, the reference variable exists, but it doesn't refer to an actual array object. The next statement creates an array object and assigns that object's reference to the reference variable.

Back to Question 3 (p. 2412)

7.6.6.14 Answer 2

D. Tom Dick Harry

7.6.6.14.1 Explanation 2

An array is an object in Java

An array is a special kind of object in Java. Stated differently, all array structures are encapsulated in objects in Java. Further, all array structures are one-dimensional. I often refer to this special kind of object as an *array object* .

An array object always has a property named **length** . The value of the **length** property is always equal to the number of elements in the array. Thus, a program can always determine the size of an array by examining its **length** property.

Instantiating an array object

An array object can be instantiated in at least two different ways:

1. By using the **new** operator in conjunction with the type of data to be stored in the array.
2. By specifying an initial value for every element in the array, in which case the **new** operator is not used.

This program uses the second of the two ways listed above.

Declaring a reference variable for an array object

The following code fragment was extracted from the method named `doArrays()`.

```
St[] myArray = {new St("Tom"),
                new St("Dick"),
                new St ("Harry")};
```

The code to the left of the assignment operator declares a reference variable named **myArray** . This reference variable is capable of holding a reference to an array object that contains an unspecified number of references to objects instantiated from the class named **St** (or any subclass of the class named *St*) .

Note the square brackets

You should note the square brackets in the declaration of the reference variable in the above code (*the declaration of a reference variable to hold a reference to an ordinary object doesn't include square brackets*) .

Create the array object

The code to the right of the assignment operator in the above fragment causes the new array object to come into being. Note that the **new** operator is not used to create the array object in this case. (*This is one of the few cases in Java, along with a literal **String** object, where it is possible to create a new object without using either the **new** operator or the **newInstance** method of the class whose name is **Class** .*)

Populate the array object

This syntax not only creates the new array object, it also populates it. The new array object created by the above code contains three elements, because three initial values were provided. The initial values are separated by commas in the initialization syntax.

Also instantiates three objects of the St class

The code in the above fragment also instantiates three objects of the class named **St** . Once the array object has come into being, each of the three elements in the array contains a reference to a new object of the class **St** . Each of those objects is initialized to contain the name of a student by using a parameterized constructor that is defined in the class.

The length property value is 3

Following execution of the above code, the **length** property of the array object will contain a value of 3, because the array contains three elements, one for each initial value that was provided.

Using the length property

The code in the following fragment uses the **length** property of the array object in the conditional clause of a **for** loop to display a **String** representation of each of the objects.

```

    for(int cnt = 0;
        cnt < myArray.length;
        cnt++){
    System.out.print(
                myArray[cnt] + " ");

```

Overridden toString method

The class named **St** , from which each of the objects was instantiated, defines an overridden **toString** method that causes the string representation of an object of that class to consist of the **String** stored in an instance variable of the object.

Thus, the **for** loop shown above displays the student names that were originally encapsulated in the objects when they were instantiated.

The class named St

The code in the following fragment shows the beginning of the class named **St** including one instance variable and a parameterized constructor.

```

    class St{
    private String name;

    public St(String name){
        this.name = name;
    }//end constructor

```

A very common syntax

This constructor makes use of a very common syntax involving the reference named **this** . Basically, this syntax says to get the value of the incoming parameter whose name is **name** and to assign that value to the instance variable belonging to *this object* whose name is also **name** .

Initializing the object of type St

Each time a new object of the **St** class is instantiated, that object contains an instance variable of type **String** whose value matches the **String** value passed as a parameter to the constructor.

Overridden toString method

The overridden **toString** method for the class named **St** is shown in the following code fragment.

```

    public String toString(){
        return name;
    } //end toString()

```

This version causes the value in the **String** object, referred to by the instance variable named **name** , to be returned when it is necessary to produce a **String** representation of the object.

Back to Question 2 (p. 2411)

7.6.6.15 Answer 1

The answer is item D, which reads as follows:

```

    "Backslash"->\
    Understand

```

7.6.6.15.1 Explanation 1

Don't confuse the compiler

If you include certain characters inside a literal **String** , you will confuse the compiler. For example, if you simply include a quotation mark (") inside a literal **String** , the compiler will interpret that as the end of the string. From that point on, everything will be out of synchronization. Therefore, in order to include a quotation mark inside a literal string, you must precede it with a backslash character like this:

```

    \"
    Multiple lines

```

If you want your string to comprise two or more physical lines, you can include a newline code inside a **String** by including the following in the string:

```

    \n
    Escape character sequences

```

These character sequences are often referred to as *escape character sequences* . Since the backslash is used as the first character in such a sequence, if you want to include a backslash in a literal string, you must do it like this:

```

    \\

```

There are some other escape sequences used in Java as well. You would do well to learn how to use them before going to an interview for a job as a Java programmer.

7.7.2 Preface

This module is part of a self-assessment test designed to help you determine how much you know about object-oriented programming using Java.

The test consists of a series of questions with answers and explanations of the answers.

The questions and the answers are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back.

I recommend that you open another copy of this document in a separate browser window and use the links to under Listings (p. 2454) to easily find and view the listings while you are reading about them.

7.7.3 Questions

7.7.3.1 Question 1 .

What output is produced by the program shown in Listing 1 (p. 2439) ?

- A. Compiler Error
- B. Runtime Error
- C. I'm OK
- D. None of the above

Listing 1 . Listing for Question 1.

```
public class Ap064{
public static void main(
                String args[]){
    new Worker().doArrays();
} //end main()
} //end class definition

class Worker{
public void doArrays(){
    double[] A = new double[2];
    A[0] = 1.0;
    A[1] = 2.0;
    Object B = A;

    System.out.println("I'm OK");
} //end doArrays()
} // end class
```

Table 7.108

Answer and Explanation (p. 2463)

7.7.3.2 Question 2

What output is produced by the program shown in Listing 2 (p. 2440) ?

- A. Compiler Error
- B. Runtime Error
- C. 1.0 2.0
- D. None of the above.

Listing 2 . Listing for Question 2.
<pre> public class Ap065{ public static void main(String args[]){ new Worker().doArrays(); } //end main() } //end class definition class Worker{ public void doArrays(){ double[] A = new double[2]; A[0] = 1.0; A[1] = 2.0; Object B = A; System.out.println(B[0] + " " + B[1]); } //end doArrays() } // end class </pre>

Table 7.109

Answer and Explanation (p. 2462)

7.7.3.3 Question 3

What output is produced by the program shown in Listing 3 (p. 2441) ?

- A. Compiler Error
- B. Runtime Error
- C. 1.0 2.0
- D. None of the above.

Listing 3 . Listing for Question 3.
<i>continued on next page</i>

```
public class Ap066{
public static void main(
                String args[]){
    new Worker().doArrays();
} //end main()
} //end class definition

class Worker{
public void doArrays(){
    double[] A = new double[2];
    A[0] = 1.0;
    A[1] = 2.0;
    Object B = A;

    double C = (double)B;
    System.out.println(
                C[0] + " " + C[1]);
} //end doArrays()
} // end class
```

7.7.3.15 Question 15

What output is produced by the program shown in Listing 15 (p. 2454) ?

- A. Compiler Error
- B. Runtime Error
- C. 0 0.0 false 0
- D. None of the above

Listing 15 . Listing for Question 15.

```

    public class Ap078{
    public static void main(
                String args[]){
        new Worker().doArrays();
    }//end main()
}//end class definition

class Worker{
    public void doArrays(){
        int[] A = new int[1];
        double[] B = new double[1];
        boolean[] C = new boolean[1];
        int[] D = new int[0];

        System.out.println(A[0] + " " +
                            B[0] + " " +
                            C[0] + " " +
                            D.length);

    }//end doArrays()
}// end class

```

7.7.6 Answers

7.7.6.1 Answer 15

C. 0 0.0 false 0

7.7.6.1.1 Explanation 15

You can initialize array elements

You can create a new array object and initialize its elements using statements similar to the following:

```
int[] A = {22, 43, 69};
X[] B = {new X(32), new X(21)};
```

What if you don't initialize array elements?

If you create a new array object without initializing its elements, the value of each element in the array is automatically initialized to a default value.

Illustrating array element default initialization

This program illustrates default initialization of `int`, `double`, and `boolean` arrays.

The default values are as follows:

- zero for all numeric values
- false for all `boolean` values
- all zero bits for char values
- null for object references

An array with no elements ...

This program also illustrates that it is possible to have an array object in Java that has no elements. In this case, the value of the `length` property for the array object is 0.

Give me an example

For example, when the user doesn't enter any arguments on the command line for a Java application, the incoming `String` array parameter to the `main` method has a length value of 0.

Another example

It is also possible that methods that return a reference to an array object may sometimes return a reference to an array whose length is 0. The method must satisfy the return type requirement by returning a reference to an array object. Sometimes, there is no data to be used to populate the array, so the method will simply return a reference to an array object with a `length` property value of 0.

Back to Question 15 (p. 2454)

7.7.6.2 Answer 14

A. Compiler Error

7.7.6.2.1 Explanation 14

Assigning array reference to type `Object`

As you learned in an earlier module, you can assign an array object's reference to an ordinary reference variable of the type `Object`. It is not necessary to indicate that the reference variable is a reference to an array by appending square brackets to the type name or the variable name.

Only works with type `Object`

However, you cannot assign an array object's reference to an ordinary reference variable of any other type. For any type other than `Object`, the reference variable must be declared to hold a reference to an array object by appending empty square brackets onto the type name or the variable name.

The first statement in the following fragment compiles successfully.

```
Object X = A;
Superclass B = A;
```

However, the second statement in the above fragment produces a compiler error under JDK 1.3, which is partially reproduced below.

```
Ap077.java:22: incompatible types
found   : Subclass[]
required: Superclass
Superclass B = A;
```

Both **Superclass** and **Object** are superclasses of the array type referred to by the reference variable named **A**. However, because of the above rule, in order to cause this program to compile successfully, you would need to modify it as shown below by adding the requisite empty square brackets to the **Superclass** type name.

```
Object X = A;
Superclass[] B = A;
```

Back to Question 14 (p. 2452)

7.7.6.3 Answer 13

```
C.  0 0 0
    0 1 2
```

7.7.6.3.1 Explanation 13

Syntactical ugliness

As I indicated in an earlier module, when declaring a reference variable that will refer to an array object, you can place the empty square brackets next to the name of the type or next to the name of the reference variable. In other words, either of the following formats will work.

```
int[][] A;
int B[][];
```

What I may not have told you at that time is that you can place some of the empty square brackets in one location and the remainder in the other location.

Really ugly syntax

This is indicated by the following fragment, which declares a reference variable for a two-dimensional array of type **int**. Then it creates the two-dimensional array object and assigns the array object's reference to the reference variable.

```
int[] A[];
A = new int[2][3];
```

While it doesn't matter which location you use for the square brackets in the declaration, it does matter how many pairs of square brackets you place in the two locations combined. The number of dimensions on the array (*if you want to think of a Java array as having dimensions*) will equal the total number of pairs of empty square brackets in the declaration of the reference variable. Thus, in this case, the array is a two-dimensional array because there is one pair of square brackets next to the type and another pair next to the variable name.

This program goes on to use nested for loops to populate the array and then to display the contents of the elements.

I personally don't use this syntax, and I hope that you don't either. However, even if you don't use it, you need to be able to recognize it when used by others.

Back to Question 13 (p. 2451)

7.7.6.4 Answer 12

C. 1 2

7.7.6.4.1 Explanation 12

The length property

This program illustrates the use of the array property named `length`, whose value always matches the number of elements in the array.

As a Java programmer, you will frequently call methods that will return a reference to an array object of a specified type, but of an unknown length. (See, for example, the method named `getEventSetDescriptors` that is declared in the interface named `BeanInfo`.) This program simulates that situation.

Returning a reference to an array

The method named `returnArray` returns a reference to an array of type `int` having two elements. Although I fixed the size of the array in this example, I could just as easily have used a random number to set a different size for the array each time the method is called. Therefore, the `doArrays` method making the call to the method named `returnArray` has no way of knowing the size of the array referred to by the reference that it receives as a return value.

All array objects have a length property

This could be a problem, but Java provides the solution to the problem in the `length` property belonging to all array objects.

The `for` loop in the method named `doArrays` uses the `length` property of the array to determine how many elements it needs to display. This is a very common scenario in Java.

Back to Question 12 (p. 2450)

7.7.6.5 Answer 11

A. Compiler Error

7.7.6.5.1 Explanation 11

You cannot cast primitive array references

You cannot cast an array reference from one primitive type to another primitive type, even if the individual elements in the array are of a type that can normally be converted to the new type.

This program attempts to cast a reference to an array of type `int[]` and assign it to a reference variable of type `double[]`. Normally, a value of type `int` will be automatically converted to type `double` whenever there is a need for such a conversion. However, this attempted cast produces the following compiler error under JDK 1.3.

```
Ap074.java:19: inconvertible types
found   : int[]
required: double[]
double[] B = (double[])A;
```

Why is this cast not allowed?

I can't give you a firm reason why such a cast is not allowed, but I believe that I have a good idea why. I speculate that this is due to the fact that the actual primitive values are physically stored in the array object, and primitive values of different types require different amounts of storage. For example, the type `int` requires 32 bits of storage while the type `double` requires 64 bits of storage.

Would require reconstructing the array object

Therefore, to convert an array object containing `int` values to an array object containing `double` values would require reconstructing the array object and allocating twice as much storage space for each element in the array.

Restriction doesn't apply to arrays of references

As you have seen from previous questions, such a casting restriction does not apply to arrays containing references to objects. This may be because the amount of storage required to store a reference to an object is the same, regardless of the type of the object. Therefore, the allowable casts that you have seen in the previous questions did not require any change to the size of the array. All that changed was some supplemental information regarding the type of objects to which the elements in the array refer.

Back to Question 11 (p. 2449)

7.7.6.6 Answer 10

C. 1.0 2.0

7.7.6.6.1 Explanation 10

Assigning array reference to variable of type `Object`

A reference to an array can be assigned to a non-array reference of the class named `Object`, as in the following statement extracted from the program, where A is a reference to an array object of type `double`.

```
Object B = A;
```

Note that there are no square brackets anywhere in the above statement. Thus, the reference to the array object is not being assigned to an array reference of the type `Object[]`. Rather, it is being assigned to an ordinary reference variable of the type `Object`.

Downcasting to an array type

Once the array reference has been assigned to the ordinary reference variable of the type `Object`, that reference variable can be downcast and used to access the individual elements in the array as illustrated in the following fragment. Note the empty square brackets in the syntax of the cast operator (`double[]`).

```
System.out.println(  
    ((double[])B)[0] + " " +  
    ((double[])B)[1]);
```

Placement of parentheses is critical

Note also that due to precedence issues, the placement of both sets of parentheses is critical in the above code fragment. You must downcast the reference variable before applying the index to that variable.

Back to Question 10 (p. 2448)

7.7.6.7 Answer 9

C. 1 2

7.7.6.7.1 Explanation 9

General array casting rule

The general rule for casting array references (*for arrays whose declared type is the name of a class or an interface*) is:

A reference to an array object can be cast to another array type if the elements of the referenced array are of a type that can be cast to the type of the elements of the specified array type.

Old rules apply here also

Thus, the general rules covering conversion and casting up and down the inheritance hierarchy and among classes that implement the same interfaces also apply to the casting of references to array objects.

A reference to an object can be cast down the inheritance hierarchy to the actual class of the object. Therefore, an array reference can also be cast down the inheritance hierarchy to the declared class for the array object.

This program declares a reference to, creates, and populates an array of the class type **Subclass** . This reference is assigned to an array reference of a type that is a superclass of the actual class type of the array. Then the superclass reference is downcast to the actual class type of the array and assigned to a different reference variable. This third reference variable is used to successfully access and display the contents of the elements in the array.

Back to Question 9 (p. 2447)

7.7.6.8 Answer 8

B. Runtime Error

7.7.6.8.1 Explanation 8

Another ClassCastException

While it is allowable to assign an array reference to an array reference variable declared for a class that is further up the inheritance hierarchy (*as illustrated earlier*) , it is not allowable to cast an array reference down the inheritance hierarchy to a subclass of the original declared class for the array.

This program declares a reference for, creates, and populates a two-element array for a class named **Superclass** . Then it downcasts that reference to a subclass of the class named **Superclass** . The compiler is unable to determine that this is a problem. However, the runtime system throws the following exception, which terminates the program at runtime.

```
java.lang.ClassCastException: [LSuperclass;
at Worker.doArrays(Ap071.java:19)
at Ap071.main(Ap071.java:9)
```

Back to Question 8 (p. 2446)

7.7.6.9 Answer 7

C. 1 2

7.7.6.9.1 Explanation 7

Assignment to superclass array reference variable

This program illustrates that, if you have a reference to an array object containing references to other objects, you can assign the array object's reference to an array reference variable whose type is a superclass of the declared class of the array object. (*As we will see later, this doesn't work for array objects containing primitive values.*)

What can you do then?

Having made the assignment to the superclass reference variable, whether or not you can do anything useful with the elements in the array (*without downcasting*) depends on many factors.

No downcast required in this case

In this case, the ability to display the contents of the objects referred to in the array was inherited from the class named **Superclass**. Therefore, it is possible to access and display a **String** representation of the objects without downcasting the array object reference from **Superclass** to the actual type of the objects.

Probably need to downcast in most cases

However, that will often not be the case. In most cases, when using a reference of a superclass type, you will probably need to downcast in order to make effective use of the elements in the array object.

Back to Question 7 (p. 2444)

7.7.6.10 Answer 6

C. 1 2

7.7.6.10.1 Explanation 6**Straightforward array application**

This is a straightforward application of Java array technology for the storage and retrieval of references to objects.

The program declares a reference to, creates, and populates a two-element array of a class named **Subclass**. The class named **Subclass** extends the class named **Superclass**, which in turn, extends the class named **Object** by default.

The super keyword

The class named **Subclass** doesn't do anything particularly useful other than to illustrate extending a class.

However, it also provides a preview of the use of the **super** keyword for the purpose of causing a constructor in a subclass to call a parameterized constructor in its superclass.

Setting the stage for follow-on questions

The main purpose for showing you this program is to set the stage for several programs that will be using this class structure in follow-on questions.

Back to Question 6 (p. 2443)

7.7.6.11 Answer 5

B. Runtime Error

7.7.6.11.1 Explanation 5**ClassCastException**

There are some situations involving casting where the compiler cannot identify an erroneous condition that is later identified by the runtime system. This is one of those cases.

This program begins with an array of type **double** []. The reference to that array is converted to type **Object**. Then it is cast to type **String** []. All of these operations are allowed by the compiler.

However, at runtime, the runtime system expects to find references to objects of type **String** in the elements of the array. What it finds instead is values of type **double** stored in the elements of the array.

As a result, a **ClassCastException** is thrown. Since it isn't caught and handled by the program, the program terminates with the following error message showing on the screen.

```

    java.lang.ClassCastException: [D
    at Worker.doArrays(Ap068.java:17)
    at Ap068.main(Ap068.java:6)

```

Back to Question 5 (p. 2442)

7.7.6.12 Answer 4

C. 1.0 2.0

7.7.6.12.1 Explanation 4

Finally, we got it right

Finally, we managed to get it all together. The program compiles and executes correctly. This program illustrates the assignment of an array object's reference to a reference variable of type **Object**, and the casting of that reference of type **Object** back to the correct array type in order to gain access to the elements in the array.

But don't go away, there is a lot more that you need to know about arrays in Java. We will look at some of those things in the questions that follow.

Back to Question 4 (p. 2441)

7.7.6.13 Answer 3

A. Compiler Error

7.7.6.13.1 Explanation 3

Must use the correct cast syntax

While it is possible to store an array object's reference in a reference variable of type **Object**, and later cast it back to an array type to gain access to the elements in the array, you must use the correct syntax in performing the cast. This is not the correct syntax for performing that cast. It is missing the empty square brackets required to indicate a reference to an array object.

A portion of the compiler error produced by JDK 1.3 is shown below:

```

    Ap066.java:17: inconvertible types
    found   : java.lang.Object
    required: double
    double C = (double)B;

```

Back to Question 3 (p. 2440)

7.7.6.14 Answer 2

A. Compiler Error

7.7.6.14.1 Explanation 2

Must cast back to an array type

This program illustrates another very important point. Although you can assign an array object's reference to a reference variable of type **Object**, you cannot gain access to the elements in the array while treating it as type **Object**. Instead, you must cast it back to an array type before you can gain access to the elements in the array object.

A portion of the compiler error produced by JDK 1.3 is shown below:

```
Ap065.java:18: array required, but java.lang.Object found
B[0] + " " + B[1]);
```

Back to Question 2 (p. 2440)

7.7.6.15 Answer 1

C. I'm OK

7.7.6.15.1 Explanation 1

Assigning array reference to type `Object`

This program illustrates a very important point. You can assign an array object's reference to an ordinary reference variable of type `Object`. Note that I didn't say `Object[]`. The empty square brackets are not required when the type is `Object`.

Standard containers or collections

Later on, when we study the various containers in the Java class libraries (*see the Java Collections Framework*), we will see that they store references to all objects, including array objects, as type `Object`. Thus, if it were not possible to store a reference to an array object in a reference variable of type `Object`, it would not be possible to use the standard containers to store references to array objects.

Because it is possible to assign an array object's reference to a variable of type `Object`, it is also possible to store array object references in containers of type `Object`.

7.8.3 Questions

7.8.3.1 Question 1 .

What output is produced by the program shown in Listing 1 (p. 2464) ?

- A. Compiler Error
- B. Runtime Error
- C. 9 17.64
- D. None of the above

Listing 1 . Listing for Question 1.

```

public class Ap079{
public static void main(
                String args[]){
    new Worker().doOverLoad();
} //end main()
} //end class definition

class Worker{
public void doOverLoad(){
    int x = 3;
    double y = 4.2;
    System.out.println(square(x) + " "
                + square(y));
} //end doOverLoad()

public int square(int y){
    return y*y;
} //end square()

public double square(double y){
    return y*y;
} //end square()
} // end class

```

Table 7.123

Answer and Explanation (p. 2479)

7.8.3.2 Question 2

What output is produced by the program shown in Listing 2 (p. 2465) ?

- A. Compiler Error
- B. Runtime Error
- C. float 9.0 double 17.64
- D. None of the above

Listing 2 . Listing for Question 2.

```
public class Ap080{
public static void main(
    String args[]){
    new Worker().doOverLoad();
} //end main()
} //end class definition

class Worker{
public void doOverLoad(){
    int x = 3;
    double y = 4.2;

    System.out.print(square(x) + " ");
    System.out.print(square(y));
    System.out.println();
} //end doOverLoad()

public float square(float y){
    System.out.print("float ");
    return y*y;
} //end square()

public double square(double y){
    System.out.print("double ");
    return y*y;
} //end square()
} // end class
```

7.8.3.6 Question 6

What output is produced by the program shown in Listing 6 (p. 2470) ?

- A. Compiler Error
- B. Runtime Error
- C. Test DumIntfc
- D. None of the above

Listing 6 . Listing for Question 6.

```

    public class Ap085{
    public static void main(
                String args[]){
        new Worker().doOverLoad();
    }//end main()
}//end class definition

class Worker{
    public void doOverLoad(){
        Test a = new Test();
        DumIntfc b = new Test();
        overLoadMthd(a);
        overLoadMthd(b);
        System.out.println();
    }//end doOverLoad()

    public void overLoadMthd(Test x){
        System.out.print("Test ");
    }//end overLoadMthd

    public void overLoadMthd(DumIntfc x){
        System.out.print("DumIntfc ");
    }//end overLoadMthd
}// end class

interface DumIntfc{
}//end DumIntfc

class Test implements DumIntfc{
}//end class Test

7.8.3.8 Question 8

What output is produced by the program shown in Listing 8 (p. 2472) ?

- A. Compiler Error
- B. Runtime Error
- C. SubC SuperC
- D. None of the above

Listing 8 . Listing for Question 8.

```
public class Ap087{
public static void main(
                String args[]){
    new Worker().doOverLoad();
} //end main()
} //end class definition

class Worker{
public void doOverLoad(){
    SubC a = new SubC();
    SuperC b = new SubC();

    SubC obj = new SubC();
    obj.overLoadMthd(a);
    obj.overLoadMthd(b);

    System.out.println();
} //end doOverLoad()

} // end class

class SuperC{
public void overLoadMthd(SuperC x){
    System.out.print("SuperC ");
} //end overLoadMthd
} //end SuperC

class SubC extends SuperC{
public void overLoadMthd(SubC x){
    System.out.print("SubC ");
} //end overLoadMthd
} //end class SubC
```

7.8.6 Answers

7.8.6.1 Answer 8

C. SubC SuperC

7.8.6.1.1 Explanation 8

While admittedly a little convoluted, this is another relatively straightforward application of method overloading using types from the class hierarchy.

Type **SubC** , **SuperC** , or **Object**?

This method defines a class named **SuperC** , which extends **Object** , and a class named **SubC** , which extends **SuperC** . Therefore, an object instantiated from the class named **SubC** can be treated as any of the following types: **SubC** , **SuperC** , or **Object** .

Two overloaded methods in different classes

Two overloaded methods named **overLoadMthd** are defined in two classes in the inheritance hierarchy. The class named **SuperC** defines a version that requires an incoming parameter of type **SuperC** . The class named **SubC** defines a version that requires an incoming parameter of type **SubC** . When called, each of these overloaded methods prints the type of its formal argument.

Two objects of type SubC

The program instantiates two objects of the **SubC** class, storing the reference to one of them in a reference variable of type **SubC** , and storing the reference to the other in a reference variable of type **SuperC** .

Call the overloaded method twice

The next step is to call the overloaded method named **overLoadMthd** twice in succession, passing each of the reference variables of type **SubC** and **SuperC** to the method.

Instance methods require an object

Because the two versions of the overloaded method are instance methods, it is necessary to have an object on which to call the methods. This is accomplished by instantiating a new object of the **SubC** class, storing the reference to that object in a reference variable named **obj** , and calling the overloaded method on that reference.

Overloaded methods not in same class

The important point here is that the two versions of the overloaded method were not defined in the same class. Rather, they were defined in two different classes in the inheritance hierarchy. However, they were defined in such a way that both overloaded versions were contained as instance methods in an object instantiated from the class named **SubC** .

No surprises

There were no surprises. When the overloaded method was called twice in succession, passing the two different reference variables as parameters, the output shows that the version that was called in each case had a formal argument type that matched the type of the parameter that was passed to the method.

Back to Question 8 (p. 2471)

7.8.6.2 Answer 7

C. Test Object

7.8.6.2.1 Explanation 7

Another straightforward application

This is another straightforward application of method overloading, which produces no surprises.

This program defines a new class named **Test** , which extends the **Object** class by default. This means that an object instantiated from the class named **Test** can be treated either as type **Test** , or as type **Object** .

The program defines two overloaded methods named **overLoadMthd** . One requires an incoming parameter of type **Test** . The other requires an incoming parameter of type **Object** . When called, each of these methods prints the type of its incoming parameter.

The program instantiates two different objects of the class **Test** , storing a reference to one of them in a reference variable of type **Test** , and storing a reference to the other in a reference variable of type **Object** .

No surprises here

Then it calls the overloaded **overLoadMthd** method twice in succession, passing the reference of type **Test** during the first call, and passing the reference of type **Object** during the second call.

As mentioned above, the output produces no surprises. The output indicates that the method selected for execution during each call is the method with the formal argument type that matches the type of parameter passed to the method.

Back to Question 7 (p. 2470)

7.8.6.3 Answer 6

C. Test DumIntfc

7.8.6.3.1 Explanation 6

Overloaded methods with reference parameters

This is a fairly straightforward application of method overloading. However, rather than requiring method parameters of primitive types as in the previous questions in this module, the overloaded methods in this program require incoming parameters of class and interface types respectively.

Type `Test` or type `DumIntfc`?

The program defines an interface named `DumIntfc` and defines a class named `Test` that implements that interface. The result is that an object instantiated from the `Test` class can be treated either as type `Test` or as type `DumIntfc` (*it could also be treated as type `Object` as well*).

Two overloaded methods

The program defines two overloaded methods named `overLoadMthd`. One requires an incoming parameter of type `Test`, and the other requires an incoming parameter of type `DumIntfc`. When called, each of the overloaded methods prints a message indicating the type of its argument.

Two objects of the class `Test`

The program instantiates two objects of the class `Test`. It assigns one of the object's references to a reference variable named `a`, which is declared to be of type `Test`.

The program assigns the other object's reference to a reference variable named `b`, which is declared to be of type `DumIntfc`. (*Remember, both objects were instantiated from the class `Test`.*)

No surprises here

Then it calls the overloaded method named `overLoadMthd` twice in succession, passing first the reference variable of type `Test` and then the reference variable of type `DumIntfc`.

The program output doesn't produce any surprises. When the reference variable of type `Test` is passed as a parameter, the overloaded method requiring that type of parameter is selected for execution. When the reference variable of type `DumIntfc` is passed as a parameter, the overloaded method requiring that type of parameter is selected for execution.

Back to Question 6 (p. 2469)

7.8.6.4 Answer 5

```
C. float 2.14748365E9
float 9.223372E18
double 4.2
```

7.8.6.4.1 Explanation 5

Another subtle method selection issue

This program illustrates a subtle issue in the automatic selection of an overloaded method based on assignment compatibility.

This program defines two overloaded methods named `square`. One requires an incoming parameter of type `float`, and the other requires an incoming parameter of type `double`.

When called, each of these methods prints the type of its formal argument along with the value of the incoming parameter as represented by its formal argument type. In other words, the value of the incoming parameter is printed after it has been automatically converted to the formal argument type.

Printout identifies the selected method

This printout makes it possible to determine which version is called for different types of parameters. It also makes it possible to determine the effect of the automatic conversion on the incoming parameter. What we are going to see is that the conversion process can introduce serious accuracy problems.

Call the method three times

The **square** method is called three times in succession, passing values of type **int** , **long** , and **double** during successive calls.

(Type **long** is a 64-bit integer type capable of storing integer values that are much larger than can be stored in type **int** . The use of this type here is important for illustration of data corruption that occurs through automatic type conversion.)

The third invocation of the **square** method, passing a **double** as a parameter, is not particularly interesting. There is a version of **square** with a matching argument type, and everything behaves as would be expected for this invocation. The interesting behavior occurs when the **int** and **long** values are passed as parameters.

Passing an int parameter

The first thing to note is the behavior of the program produced by the following code fragment.

```
int x = 2147483647;
square(x);
```

The above fragment assigns a large integer value (2147483647) to the **int** variable and passes that variable to the **square** method. This fragment produces the following output on the screen:

```
float 2.14748365E9
```

As you can see, the system selected the overloaded method that requires an incoming parameter of type **float** for execution in this case (rather than the version that requires type **double**).

Conversion from int to float loses accuracy

Correspondingly, it converted the incoming **int** value to type **float** , losing one decimal digit of accuracy in the process. (The original **int** value contained ten digits of accuracy. This was approximated by a nine-digit **float** value with an exponent value of 9.)

This seems like an unfortunate choice of overloaded method. Selecting the other version that requires a **double** parameter as input would not have resulted in any loss of accuracy.

A more dramatic case

Now, consider an even more dramatic case, as illustrated in the following fragment where a very large **long** integer value(9223372036854775807) is passed to the **square** method.

```
long y = 9223372036854775807L;
square(y);
```

The above code fragment produced the following output:

```
float 9.223372E18
```

A very serious loss of accuracy

Again, unfortunately, the system selected the version of the **square** method that requires a **float** parameter for execution. This caused the **long** integer to be converted to a **float** . As a result, the **long** value containing 19 digits of accuracy was converted to an estimate consisting of only seven digits plus an exponent. (Even if the overloaded **square** method requiring a **double** parameter had been

selected, the conversion process would have lost about three digits of accuracy, but that would have been much better than losing twelve digits of accuracy.)

The moral to the story is ...

Don't assume that just because the system knows how to automatically convert your integer data to floating data, it will protect the integrity of your data. Oftentimes it won't.

To be really safe ...

To be really safe, whenever you need to convert either **int** or **long** types to floating format, you should write your code in such a way as to ensure that it will be converted to type **double** instead of type **float**.

For example, the following modification would solve the problem for the **int** data and would greatly reduce the magnitude of the problem for the **long** data. Note the use of the **(double)** cast to force the **double** version of the **square** method to be selected for execution.

```
int x = 2147483647;
square((double)x);
long y = 9223372036854775807L;
square((double)y);
```

The above modification would cause the program to produce the following output:

```
double 2.147483647E9
double 9.223372036854776E18
double 4.2
```

This output shows no loss of accuracy for the **int** value, and the loss of three digits of accuracy for the long value.

*(Because a **long** and a **double** both store their data in 64 bits, it is not possible to convert a very large **long** value to a **double** value without some loss in accuracy, but even that is much better than converting a 64-bit **long** value to a 32-bit **float** value.)*

Back to Question 5 (p. 2467)

7.8.6.5 Answer 4

C. 9 17.64

7.8.6.5.1 Explanation 4

When the **square** method is called on an object of the **Subclass** type passing an **int** as a parameter, there is an exact match to the required parameter type of the **square** method defined in that class. Thus, the method is properly selected and executed.

When the **square** method is called on an object of the **Subclass** type passing a **double** as a parameter, the version of the **square** method defined in the **Subclass** type is not selected. The **double** value is not assignment compatible with the required type of the parameter (*an **int** is narrower than a **double***).

Having made that determination, the system continues searching for an overloaded method with a required parameter that is either type **double** or assignment compatible with **double**. It finds the version inherited from **Superclass** that requires a **double** parameter and calls it.

The bottom line is, overloaded methods can occur up and down the inheritance hierarchy.

Back to Question 4 (p. 2466)

7.8.6.6 Answer 3

A. Compiler Error

7.8.6.6.1 Explanation 3**Return type is not a differentiating feature**

This is not a subtle issue. This program illustrates the important fact that the return type does not differentiate between overloaded methods having the same name and formal argument list.

For a method to be overloaded, two or more versions of the method must have the same name and different formal arguments lists.

The return type can be the same, or it can be different (*it can even be void*) . It doesn't matter.

These two methods are not a valid overload

This program attempts to define two methods named `square` , each of which requires a single incoming parameter of type `double` . One of the methods casts its return value to type `int` and returns type `int` . The other method returns type `double` .

The JDK 1.3 compiler produced the following error:

```
Ap081.java:28: square(double) is already defined
in Worker
```

```
public double square(double y){
```

Back to Question 3 (p. 2465)

7.8.6.7 Answer 2

C. float 9.0 double 17.64

7.8.6.7.1 Explanation 2**This program is a little more subtle**

Once again, the program defines two overloaded methods named `square` . However, in this case, one of the methods requires a single incoming parameter of type `float` and the other requires a single incoming parameter of type `double` . (*Suffice it to say that the `float` type is similar to the `double` type, but with less precision. It is a floating type, not an integer type. The `double` type is a 64-bit floating type and the `float` type is a 32-bit floating type.*)

Passing a type `int` as a parameter

This program does not define a method named `square` that requires an incoming parameter of type `int` . However, the program calls the `square` method passing a value of type `int` as a parameter.

What happens to the `int` parameter?

The first question to ask is, will this cause one of the two overloaded methods to be called, or will it cause a compiler error? The answer is that it will cause one of the overloaded methods to be called because a value of type `int` is assignment compatible with both type `float` and type `double` .

Which overloaded method will be called?

Since the type `int` is assignment compatible with type `float` and also with type `double` , the next question is, which of the two overloaded methods will be called when a value of type `int` is passed as a parameter?

Learn through experimentation

I placed a print statement in each of the overloaded methods to display the type of that method's argument on the screen when the method is called. By examining the output, we can see that the method

with the **float** parameter was called first (corresponding to the parameter of type **int**). Then the method with the **double** parameter was called (corresponding to the parameter of type **double**).

Converted int to float

Thus, the system selected the overloaded method requiring an incoming parameter of type **float** when the method was called passing an **int** as a parameter. The value of type **int** was automatically converted to type **float** .

In this case, it wasn't too important which method was called to process the parameter of type **int** , because the two methods do essentially the same thing – compute and return the **square** of the incoming value.

However, if the behavior of the two methods were different from one another, it could make a lot of difference, which one gets called on an assignment compatible basis. (Even in this case, it makes some difference. As we will see later, when a very large **int** value is converted to a **float** , there is some loss in accuracy. However, when the same very large **int** value is converted to a **double** , there is no loss in accuracy.)

Avoiding the problem

One way to avoid this kind of subtle issue is to avoid passing assignment-compatible values to overloaded methods.

Passing assignment-compatible values to overloaded methods allows the system to resolve the issue through automatic type conversion. Automatic type conversion doesn't always provide the best choice.

Using a cast to force your choice of method

Usually, you can cast the parameter values to a specific type before calling the method and force the system to select your overloaded method of choice.

For example, in this problem, you could force the method with the **double** parameter to handle the parameter of type **int** by using the following cast when the method named **square** is called:

```
square((double)x)
```

However, as we will see later, casting may not be the solution in every case.

Back to Question 2 (p. 2464)

7.8.6.8 Answer 1

C. 9 17.64

7.8.6.8.1 Explanation 1

What is method overloading?

A rigorous definition of method overloading is very involved and won't be presented here. However, from a practical viewpoint, a method is overloaded when two or more methods having the same name and different formal argument lists are defined in the class from which an object is instantiated, or are inherited into an object by way of superclasses of that class.

How does the compiler select among overloaded methods?

The exact manner in which the system determines which method to call in each particular case is also very involved. Basically, the system determines which of the overloaded methods to execute by matching the types of parameters passed to the method to the types of arguments defined in the formal argument list.

Assignment compatible matching

However, there are a number of subtle issues that arise, particularly when there isn't an exact match. In selecting the version of the method to call, Java supports the concept of an "assignment compatible" match (or possibly more than one assignment compatible match) .

Briefly, assignment compatibility means that it would be allowable to assign a value of the type that is passed as a parameter to a variable whose type matches the specified argument in the formal argument list.

Selecting the best match

According to *Java Language Reference* by Mark Grand,

"If more than one method is compatible with the given arguments, the method that most closely matches the given parameters is selected. If the compiler cannot select one of the methods as a better match than the others, the method selection process fails and the compiler issues an error message."

Understanding subtleties

If you plan to be a Java programmer, you must have some understanding of the subtle issues involving overloaded methods, and the relationship between *overloaded* methods and *overridden* methods. Therefore, the programs in this module will provide some of that information and discuss some of the subtle issues that arise.

Even if you don't care about the subtle issues regarding method overloading, many of those issues really involve automatic type conversion. You should study these questions to learn about the problems associated with automatic type conversion.

This program is straightforward

However, there isn't anything subtle about the program for Question 1 (p. 2464) . This program defines two overloaded methods named `square` . One requires a single incoming parameter of type `int` . The other requires a single incoming parameter of type `double` . Each method calculates and returns the square of the incoming parameter.

The program calls a method named `square` twice in succession, and displays the values returned by those two invocations. In the first case, an `int` value is passed as a parameter. This causes the method with the formal argument list of type `int` to be called.

In the second case, a `double` value is passed as a parameter. This causes the method with the formal argument list of type `double` to be called.

Overloaded methods may have different return types

Note in particular that the overloaded methods have different return types. One method returns its value as type `int` and the other returns its value as type `double` . This is reflected in the output format for the two return vales as shown below:

7.9.6 Answers

7.9.6.1 Answer 10

A. Compiler Error

7.9.6.1.1 Explanation 10

Variables declared `private` really are `private`

The code in the following fragment attempts to ignore the setter and getter methods and directly access the `private` instance variable named `x` in the object referred to by the reference variable named `obj` .

```
obj.x = 10;
System.out.println(obj.x);
```

This produces a compiler error. The compiler error produced by JDK 1.3 is reproduced below.

```

Ap099.java:19: x has private access in
NewClass
  obj.x = 10;
  ^
Ap099.java:20: x has private access in
NewClass
  System.out.println(obj.x);
  ^

```

Back to Question 10 (p. 2489)

7.9.6.2 Answer 9

C. 10

7.9.6.2.1 Explanation 9

A setter and a getter

This is a very simple program that uses a setter (*modifier or mutator*) method named **setX** to set the value 10 in a property named **x** that is stored in an instance variable named **y** in an object instantiated from the class named **NewClass** ..

The program also uses a getter (*accessor*) method named **getX** to get and display the value of the property named **x** . (Note that according to *JavaBeans design patterns*, the name of the property is unrelated to the name of variable in which the property value is stored.)

Back to Question 9 (p. 2488)

7.9.6.3 Answer 8

D. 5

7.9.6.3.1 Explanation 8

Hide your data and expose your methods

For reasons that I won't go into here, good object-oriented design principles state that in almost all cases where an instance variable is not declared to be **final** , it should be declared **private** . (A *final* variable behaves like a constant.)

What is private access?

When an instance variable is declared **private** , it is accessible only by methods of the class in which it is defined. Therefore, the only way that the "outside world" can gain access to a **private** instance variable is by going through an (*usually public*) instance method of the object.

Accessor, modifier, mutator, setter, and getter methods

Historically, methods that have been defined for the purpose of exposing **private** instance variables to the outside world have been referred to as *accessor* and *modifier* methods. (*Modifier methods are also sometimes called mutator methods.*)

(Note that since the advent of Sun's *JavaBeans Component design patterns*, these methods have also come to be known as *getter methods* and *setter methods* in deference to the design-pattern naming conventions for the methods.)

A private instance variable with an initializer

The class named **NewClass** declares a **private** instance variable named **x** and initializes its value to 2, as shown in the following code fragment:

```
private int x = 2;
```

Two constructors

The class contains both a *noarg* constructor and a *parameterized* constructor as shown in the following fragment:

```
public NewClass(){
} //end constructor

public NewClass(int x){
    this.x = x;
} //end constructor
```

Calling the noarg constructor

If an object of the class is instantiated by calling the *noarg* constructor, the initial value of 2 remains intact, and that object contains an instance variable with an initial value of 2.

Calling the parameterized constructor

If an object of the class is instantiated by calling the parameterized constructor, the initial value of 2 is overwritten by the value of the incoming parameter to the parameterized constructor. In this case, that value is 5, because the object is instantiated by the following code fragment that passes the literal value 5 to the parameterized constructor. Thus, the initial value of the instance variable in that object is 5.

```
NewClass obj = new NewClass(5);
```

A getter method

Because the instance variable named `x` is **private**, it cannot be accessed directly for display by the code in the `makeObj` method of the `Worker` class. However, the `NewClass` class provides the following public *getter* or *accessor* method that can be used to get the value stored in the instance variable.

(The name of this method complies with JavaBeans design patterns. If you examine the name carefully, you will see why Java programmers often refer to methods like this as getter methods.)

```
public int getX(){
    return x;
} //end getX()
```

Calling the getter method

Finally, the second statement in the following code fragment calls the getter method on the `NewClass` object to get and display the value of the instance variable named `x`.

```
NewClass obj = new NewClass(5);
System.out.println(obj.getX());
```

Back to Question 8 (p. 2487)

7.9.6.4 Answer 7

C. Object containing 0, 0.0, false

7.9.6.4.1 Explanation 7**Default initialization values**

The purpose of this question is to confirm that you understand the default initialization of instance variables in an object when you don't write code to cause the initialization of the instance variable to differ from the default.

By default, all instance variables in a new object are initialized with default values if you don't provide a constructor (*or other mechanism*) that causes them to be initialized differently from the default.

- All instance variables of the numeric types are initialized to the value of zero for the type. This program illustrates default initialization to zero for **int** and **double** types.
- Instance variables of type **boolean** are initialized to false.
- Instance variables of type **char** are initialized to a 16-bit Unicode character for which all sixteen bits have been set to zero. I didn't include initialization of the **char** type in the output of this program because the **default** char value is not printable.
- Instance variables of reference types are initialized to null.

Back to Question 7 (p. 2486)

7.9.6.5 Answer 6

C. Object containing 5

7.9.6.5.1 Explanation 6**A parameterized constructor**

This program illustrates the straightforward use of a parameterized constructor.

The class named **NewClass** defines a parameterized constructor that requires an incoming parameter of type **int** .

(For good design practice, the class also defines a noarg constructor, even though it isn't actually used in this program. This makes it available if needed later when someone extends the class.)

Both constructors are shown in the following code fragment.

```

    public NewClass(){
    }//end constructor

    public NewClass(int x){
        this.x = x;
    }//end constructor

```

The parameterized constructor stores its incoming parameter named **x** in an instance variable of the class, also named **x** .

*(The use of the keyword **this** is required in this case to eliminate the ambiguity of having a local parameter with the same name as an instance variable. This is very common Java programming style that you should recognize and understand.)*

Call the parameterized constructor

The following code fragment calls the parameterized constructor, passing the literal **int** value of 5 as a parameter.

```
NewClass obj = new NewClass(5);
```

Hopefully you will have no difficulty understanding the remaining code in the program that causes the value stored in the instance variable named `x` to be displayed on the computer screen.

Back to Question 6 (p. 2485)

7.9.6.6 Answer 5

A. Compiler Error

7.9.6.6.1 Explanation 5

If you define any constructors, ...

The discussion for Question 4 (p. 2483) explained that if you define any constructor in a new class, you must define all constructors that will ever be needed for that class. When you define one or more constructors, the default `noarg` constructor is no longer provided by the system on your behalf.

Question 4 (p. 2483) illustrated a simple manifestation of a problem arising from the failure to define a `noarg` constructor that would be needed later. The reason that it was needed later was that the programmer attempted to explicitly use the non-existent `noarg` constructor to create an instance of the class.

A more subtle problem

The problem in this program is more subtle. Unless you (*or the programmer of the superclasses*) specifically write code to cause the system to behave otherwise, each time you instantiate an object of a class, the system automatically calls the `noarg` constructor on superclasses of that class up to and including the class named **Object**. If one or more of those superclasses don't have a `noarg` constructor, unless the author of the subclass constructor has taken this into account, the program will fail to compile.

Calling a non-existing `noarg` constructor

This program attempts to instantiate an object of a class named **Subclass**, which extends a class named **Superclass**. By default, when attempting to instantiate the object, the system will attempt to call a `noarg` constructor defined in **Superclass**.

Superclass has no `noarg` constructor

The **Superclass** class defines a parameterized constructor that requires a single incoming parameter of type `int`. However, it does not also define a `noarg` constructor. Because the parameterized constructor is defined, the default `noarg` constructor does not exist. As a result, JDK 1.3 produces the following compiler error:

```
Ap094.java:40: cannot resolve symbol
```

```
symbol  : constructor Superclass ()
location: class Superclass
public Subclass(){
```

Back to Question 5 (p. 2484)

7.9.6.7 Answer 4

A. Compiler Error

7.9.6.7.1 Explanation 4

Constructors

Java uses the following kinds of constructors:

- Those that take arguments, often referred to as *parameterized constructors*, which typically perform initialization on the new object using parameter values.
- Those that don't take arguments, often referred to as *default* or *noarg* constructors, which perform default initialization on the new object.
- Those that don't take arguments but perform initialization on the new object in ways that differ from the default initialization.

Constructor definition is optional

You are not required to define a constructor when you define a new class. If you don't define a constructor for your new class, a default constructor will be provided on your behalf. This constructor requires no argument, and it is typically used in conjunction with the new operator to create an instance of the class using statements such as the following:

```
NewClass obj = new NewClass();
```

The default constructor

The default constructor typically does the following:

- Calls the *noarg* constructor of the superclass
- Assists in the process of allocating and organizing memory for the new object
- Initializes all instance variables of the new object with the following four default values:
 - numeric = 0,
 - boolean = false,
 - char = all zero bits
 - reference = null

Are you satisfied with default values?

As long as you are satisfied with the default initialization of all instance variables belonging to the object, there is no need for you to define a constructor of your own.

However, in the event that you have initialization needs that are not satisfied by the default constructor, you can define your own constructor. Your new constructor may or may not require arguments. (*In case you have forgotten, the name of the constructor is always the same of the name of the class in which it is defined.*)

A non-default *noarg* constructor

If your new constructor doesn't require arguments, you may need to write code that performs initialization in ways that differ from the default initialization. For example, you might decide that a particular **double** instance variable needs to be initialized with a random number each time a new object is instantiated. You could do that with a constructor of your own design that doesn't take arguments by defining the constructor to get initialization values from an object of the **Random** class.

A parameterized constructor

If your new constructor does take arguments, (*a parameterized constructor*) you can define as many overloaded versions as you need. Each overloaded version must have a formal argument list that differs from the formal argument list of all of the other overloaded constructors for that class.

(*The rules governing the argument list for overloaded constructors are similar to the rules governing the argument list for overloaded methods, which were discussed in a previous module.*)

Use parameter values for initialization

In this case, you will typically define your parameterized constructors to initialize some or all of the instance variables of the new object using values passed to the constructor as parameters.

What else can a constructor do?

You can also cause your new constructor to do other things if you so choose. For example, if you know how to do so, you could cause your constructor (*with or without parameters*) to play an audio clip each time a new object is instantiated. You could use a parameter to determine which audio clip to play in each particular instance.

The punch line

So far, everything that I have said is background information for this program. Here is the punch line insofar as this program is concerned.

If you define any constructor in your new class, you must define all constructors that your new class will ever need.

If you define any constructor, the default constructor is no longer provided on your behalf. If your new class needs a *noarg* constructor (*and it probably does, but that may not become apparent until later when you or someone else extends your class*) you must define the *noarg* version in addition to the other overloaded versions that you define.

A violation of the rule

This program violated the rule given above. It defined the parameterized constructor for the class named **NewClass** shown below

```
public NewClass(int x){
    this.x = x;
} //end constructor
```

However, the program did not also define a *noarg* constructor for the **NewClass** class.

Calling the *noarg* constructor

The code in the **makeObj** method of the **Worker** class attempted to instantiate a new object using the following code:

```
NewClass obj = new NewClass();
```

Since the class definition didn't contain a definition for a *noarg* constructor, the following compiler error was produced by JDK 1.3.

```
Ap093.java:18: cannot resolve symbol
symbol  : constructor NewClass
()
location: class NewClass
    NewClass obj = new NewClass();
```

Back to Question 4 (p. 2483)

7.9.6.8 Answer 3

C. An Object

7.9.6.8.1 Explanation 3

We finally got it right!

Did you identify the errors in the previous two programs before looking at the answers?

This program declares the class named `NewClass` correctly and uses the `new` operator correctly in conjunction with the default `noarg` constructor for the `NewClass` class to create a new instance of the class (*an object*) .

Making the class public

One of the things that I could do differently would be to make the declaration for the `NewClass` class public (*as shown in the following code fragment*) .

```
public class NewClass{
public String toString(){
    return "An Object";
} //end toString()
} //end NewClass
```

I am a little lazy

The reason that I didn't declare this class `public` (*and haven't done so throughout this series of modules*) is because the source code for all `public` classes and interfaces must be in separate files. While that is probably a good requirement for large programming projects, it is overkill for simple little programs like I am presenting in this group of self-assessment modules.

Dealing with multiple files

Therefore, in order to avoid the hassle of having to deal with multiple source code files for every program, I have been using *package-private* access for class definitions other than the controlling class (*the controlling class is declared public*) . Although I won't get into the details at this point, when a class is not declared public, it is common to say that it has *package-private* access instead of `public` access.

Back to Question 3 (p. 2482)

7.9.6.9 Answer 2

A. Compiler Error

7.9.6.9.1 Explanation 2

Java is a case-sensitive language

Java keywords must be written exactly as specified. The keyword `class` cannot be written as `Class` , which is the problem with this program.

The inappropriate use of the upper-case C in the word `Class` caused the following compiler error.

```
Ap091.java:25: 'class' or 'interface' expected
```

```
Class NewClass{
```

The solution to the problem

This problem can be resolved by causing the first character in the keyword `class` to be a lower-case character as shown in the following code fragment.

```

class NewClass{
public String toString(){
    return "An Object";
} //end toString()
} //end NewClass

```

Back to Question 2 (p. 2481)

7.9.6.10 Answer 1

A. Compiler Error

7.9.6.10.1 Explanation 1

Instantiating an object

There are several ways to instantiate an object in Java:

- Use the **newInstance** method of the class named **Class** .
- Reconstruct a serialized object using an I/O **readObject** method.
- Create an initialized array object such as {1,2,3}.
- Create a **String** object from a literal string such as "A String".
- Use the **new** operator.

Of all of these, the last two are by far the most common.

What you cannot do!

You cannot instantiate a new object using code like the following code fragment that was extracted from this program.

```
NewClass obj = NewClass();
```

This program produces the following compiler error:

```

Ap090.java:18: cannot resolve symbol
symbol   : method NewClass ()
location: class Worker
    NewClass obj = NewClass();

```

The solution to the problem

This problem can be solved by inserting the **new** operator to the left of the constructor as shown in the following code fragment.

```
NewClass obj = new NewClass();
```

7.10.2 Preface

This module is part of a self-assessment test designed to help you determine how much you know about object-oriented programming using Java.

The test consists of a series of questions with answers and explanations of the answers.

The questions and the answers are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back.

I recommend that you open another copy of this document in a separate browser window and use the links to under Listings (p. 2509) to easily find and view the listings while you are reading about them.

7.10.3 Questions

7.10.3.1 Question 1 .

What output is produced by the program shown in Listing 1 (p. 2501) ?

- A. Compiler Error
- B. Runtime Error
- C. 1, 2
- D. 5, 10
- E. None of the above

¹⁸This content is available online at <<http://cnx.org/content/m45270/1.5/>>.

Listing 1 . Listing for Question 1.

```

    public class Ap100{
    public static void main(
                String args[]){
        new Worker().makeObj();
    }//end main()
}//end class definition

class Worker{
    public void makeObj(){
        Subclass obj = new Subclass();
        System.out.println(obj.getX() +
                ", " + obj.getY());
    }//end makeObj()
}// end class

class Superclass{
    private int x = 1;

    public Superclass(){
        x = 5;
    }//end constructor

    public int getX(){
        return x;
    }//end getX()
}//end Superclass

class Subclass extends Superclass{
    private int y = 2;

    public Subclass(){
        super();
        y = 10;
    }//end constructor

    public int getY(){
        return y;
    }//end getY()
}//end Subclass

7.10.3.2 Question 2

What output is produced by the program shown in Listing 2 (p. 2503) ?

- A. Compiler Error

- B. Runtime Error
- C. 1, 2
- D. 5, 2
- E. 5, 10
- F. 20, 10
- G. None of the above

Listing 2 . Listing for Question 2.

```

    public class Ap101{
    public static void main(
                String args[]){
        new Worker().makeObj();
    }//end main()
}//end class definition

class Worker{
    public void makeObj(){
        Subclass obj = new Subclass();
        System.out.println(obj.getX() +
                ", " + obj.getY());
    }//end makeObj()
}// end class

class Superclass{
    private int x = 1;

    public Superclass(){
        x = 5;
    }//end constructor

    public Superclass(int x){
        this.x = x;
    }//end constructor

    public int getX(){
        return x;
    }//end getX()
}//end Superclass

class Subclass extends Superclass{
    private int y = 2;

    public Subclass(){
        super(20);
        y = 10;
    }//end constructor

    public int getY(){
        return y;
    }//end getY()
}//end Subclass

7.10.6 Answers

7.10.6.1 Answer 10

C. 38.48451000647496
12.566370614359172

7.10.6.1.1 Explanation 10

Use static methods sparingly

Good object-oriented design dictates that **static** methods be used sparingly, and only in those situations where they are appropriate. As you might guess, not all authors will agree on the issue of appropriateness in all cases.

Is this an appropriate use of a static method?

However, I believe that most authors will agree that this program illustrates an appropriate use of a **static** method.

No persistence requirement

This **static** method computes and returns a result on a non-persistent basis. That is to say, there is no attempt by the **static** method to save any historical information from one call of the method to the next. *(Of course, the method that calls the **static** method can save whatever it chooses to save.)*

Avoiding wasted computer resources

In situations such as this, it would often be a waste of computer resources to require a program to instantiate an object and call an instance method on that object just to be able to delegate a non-persistent computation to that method. *(This is just about as close to a global method as you can get in Java.)*

Computing the area of a circle

In this program, the **Worker** class provides a **static** method named **area** that receives a **double** parameter representing the radius of a circle. It computes and returns the area of the circle as a **double** value. The **static** method named **area** is shown in the following code fragment.

```
class Worker{
public static double area(double r){
return r*r*Math.PI;
}
```

```

    }//end area()

}// end class

```

As a driver, the **main** method of the controlling class calls the **area** method twice in succession, passing different values for the radius of a circle. In each case, the **main** method receives and displays the value that is returned by the **area** method representing the area of a circle.

Static methods in the class libraries

If you examine the Java API documentation carefully, you will find numerous examples of **static** methods that produce and return something on a non-persistent basis. (*Again, non-persistent in this context means that no attempt is made by the **static** method to store any historical information. It does a job, forgets it, and goes on to the next job when it is called again.*)

Factory methods

For example, the alphabetical index of the JDK 1.3 API lists several dozen **static** methods named **getInstance**, which are defined in different classes. These methods, which usually produce and return a reference to an object, are often called *factory methods*.

Here is the text from the API documentation describing one of them:

```

getInstance(int)
Static method in class java.awt.AlphaComposite
Creates an AlphaComposite object with the specified rule.

```

Back to Question 10 (p. 2508)

7.10.6.2 Answer 9

C. 5

7.10.6.2.1 Explanation 9

Going through a reference to ...

This program illustrates a rather convoluted methodology by which a **static** method can gain access to an instance member of an object.

```

class Worker{
private int x = 5;
public static void staticMethod(){
    System.out.println(
        new Worker().getX());
} //end staticMethod()

public int getX(){
    return x;
} //end getX()

} // end class

```

In this example, the **static** method calls a getter method on a reference to an object to gain access to an instance variable belonging to that object. This is what I meant in the discussion in the previous question when I said *"going through a reference to an object of the class."*

Back to Question 9 (p. 2508)

7.10.6.3 Answer 8

A. Compiler Error

7.10.6.3.1 Explanation 8**A static method cannot access ...**

A **static** method cannot access non-static or instance members of its class without going through a reference to an object of the class.

In this program, the **static** method attempts to directly access the instance variable named `x`. As a result, JDK 1.3 produces the following compiler error:

```
Ap107.java:17: non-static variable x
cannot be referenced from a static context
```

```
System.out.println(x);
```

Back to Question 8 (p. 2507)

7.10.6.4 Answer 7

C. A static method

7.10.6.4.1 Explanation 7**Using a static method**

This is a very straightforward example of the use of a **static** method.

When a method is declared **static**, it is not necessary to instantiate an object of the class containing the method in order to access the method (*although it is possible to do so unless the class is declared abstract*). All that is necessary to access a **public static** method is to refer to the name of the class in which it is defined and the name of the method joined by a period.

(A method that is declared **static** is commonly referred to as a class method. If the method is not declared **public**, it may not be accessible from your code.)

Accessing the static method

This is illustrated by the following fragment from the program, with much of the code deleted for brevity.

```
//...
    Worker.staticMethod();
//...

class Worker{
    public static void staticMethod(){
        //...
    }//end staticMethod()

}// end class
```

The class named **Worker** defines a **public static** method named **staticMethod**. A statement in the **main** method of the controlling class calls the method by referring to the name of the class and the name of the method joined by a period.

When should you use static methods?

Static methods are very useful as utility methods (*getting the absolute value of a number, for example*)

In my opinion, you should almost never use a **static** method in any circumstance that requires the storage and use of data from one call of the method to the next. In other words, a **static** method may be appropriate for use when it performs a specific task that is completed each time it is called without the requirement for data to persist between calls.

The **Math** class contains many good examples of the use of **static** methods, such as **abs** , **acos** , **asin** , etc.

Back to Question 7 (p. 2506)

7.10.6.5 Answer 6

D. 3.1415927

7.10.6.5.1 Explanation 6**Using a public static final member variable**

The class named **Worker** declares and initializes a member variable named **fPi** .

final

Because it is declared **final** , it is not possible to write code that will change its value after it has been initialized.

static

Because it is declared **static** , it can be accessed without a requirement to instantiate an object of the **Worker** class. All that is necessary to access the variable is to refer to the name of the class and the name of the variable joined by a period.

Because it is **static** , it can also be accessed by **static** methods.

public

Because it is declared **public** , it can be accessed by any code in any method in any object that can locate the class.

Type float is less precise than type double

Because the initialized value is cast from the type **double** that is returned by **Math.PI** to type **float** , an 8-digit approximation is stored in the variable named **fPi** .

The **double** value returned by **Math.PI** is 3.141592653589793

The cast to type **float** reduces the precision down to 3.1415927

Back to Question 6 (p. 2506)

7.10.6.6 Answer 5

C. 5

7.10.6.6.1 Explanation 5**Using a final local variable**

Well, I finally got rid of all the bugs. This program uses a **final** local variable properly. The program compiles and executes without any problems.

Back to Question 5 (p. 2505)

7.10.6.7 Answer 4

A. Compiler Error

7.10.6.7.1 Explanation 4

The purpose of this question is to see if you are still awake.

What caused the compiler error?

The statement that caused the compiler error in this program is shown below. Now that you know that there was a compiler error, and you know which statement caused it, do you know what caused it?

```
public final int x = 5;
```

Using public static final member variables

As I mentioned in an earlier question, the **final** keyword can be applied either to local variables or to member variables. When applying the **final** keyword to member variables, it is common practice to declare them to be both **public** and **static** in order to make them as accessible as possible. For example, the **math** class has a **final** variable that is described as follows:

```
public static final double PI
```

The double value that is closer than any other to pi, the ratio of the circumference of a circle to its diameter.

The constant named PI

You may recognize the constant named **PI** from your high school geometry class.

Whenever you need the value for the constant **PI**, you shouldn't have to instantiate an object just to get access to it. Furthermore, your class should not be required to have any special package relationship with the **Math** class just to get access to **PI**.

The good news ...

Because **PI** is declared to be both **public** and **static** in the **Math** class, it is readily available to any code in any method in any Java program that has access to the standard Java class library.

How is PI accessed?

PI can be accessed by using an expression as simple as that shown below, which consists simply of the name of the class and the name of the variable joined by a period (*Math.PI*).

```
double piRSquare = Math.PI * R * R;
```

No notion of public local variables

As a result of the above, many of you may have become accustomed to associating the keyword **public** with the keyword **final**. However, if you missed this question and you have read the explanation to this point, you must also remember that there is no notion of **public** or **private** for local variables. Therefore, when this program was compiled under JDK 1.3, a compiler error was produced. That compiler error is partially reproduced below:

```
Ap103.java:16: illegal start of
expression
public final int x = 5;
```

Back to Question 4 (p. 2504)

7.10.6.8 Answer 3

A. Compiler Error

7.10.6.8.1 Explanation 3

The **final** keyword

The **final** keyword can be applied in a variety of ways in Java. This includes:

- final parameters
- final methods
- final classes
- final variables (*constants*)

Behaves like a constant

When the **final** keyword is applied to a variable in Java, that causes the variable to behave like a constant. In other words, the value of the variable must be initialized when it is declared, and it cannot be changed thereafter (*see the exception discussed below*) .

Apply to local or member variables

The **final** keyword can be applied to either local variables or member variables. (*In case you have forgotten, local variables are declared inside a method or constructor, while member variables are declared inside a class, but outside a method.*)

So, what is the problem?

The problem with this program is straightforward. As shown in the following code fragment, after declaring a **final** local variable and initializing its value to 5, the program attempts to change the value stored in that variable to 10. This is not allowed.

```
        final int x = 5;
    x = 10;
```

A compiler error

JDK 1.3 produces the following error message:

```
Ap102.java:17: cannot assign a value to
final
variable x

        x = 10;
```

An interesting twist - blank finals

An interesting twist of the use of the **final** keyword with local variables is discussed below.

Background information

Regardless of whether or not the local variable is declared **final** , the compiler will not allow you to access the value in a local variable if that variable doesn't contain a value. This means that you must always either initialize a local variable or assign a value to it before you can access it.

So, what is the twist?

Unlike **final** member variables of a class, the Java compiler and runtime system do not require you to initialize a **final** local variable when you declare it. Rather, you can wait and assign a value to it later.

(Some authors refer to this as a *blank final*.) However, once you have assigned a value to a **final** local variable, you cannot change that value later.

The bottom line

Whether you initialize the **final** local variable when you declare it, or assign a value to it later, the result is the same. It behaves as a constant. The difference is that if you don't initialize it when you declare it, you cannot access it until after you assign a value to it.

Back to Question 3 (p. 2504)

7.10.6.9 Answer 2

F. 20, 10

7.10.6.9.1 Explanation 2

Calling a parameterized constructor

This is a relatively straightforward implementation of the use of the **super** keyword in a subclass constructor to call a parameterized constructor in the superclass.

The interesting code in the program is highlighted in the following fragment. Note that quite a lot of code was deleted from the fragment for brevity.

```

class Superclass{
//...

public Superclass(int x){
//...
} //end constructor

//...
} //end Superclass

class Subclass extends Superclass{
//...

public Subclass(){
    super(20);
//...
} //end constructor

//...
} //end Subclass

```

Using the super keyword

The code that is of interest is the use of **super(20)** as the first executable statement in the **Subclass** constructor to call the parameterized constructor in the superclass, passing a value of 20 as a parameter to the parameterized constructor.

Note that when the **super** keyword is used in this fashion in a constructor, it must be the **first** executable statement in the constructor.

As before, the program plays around a little with initial values for instance variables to see if you are alert, but the code that is really of interest is highlighted in the above fragment.

Back to Question 2 (p. 2501)

7.10.6.10 Answer 1

D. 5, 10

7.10.6.10.1 Explanation 1

The execution of constructors

The purpose of this question and the associated answer is to illustrate explicitly what happens automatically by default regarding the execution of constructors.

The Subclass constructor

This program defines a class named **Subclass** , which extends a class named **Superclass** . A portion of the **Subclass** definition, including its *noarg* constructor is shown in the following code fragment. (The class also defines a getter method, which was omitted here for brevity.)

```
class Subclass extends Superclass{
private int y = 2;

public Subclass(){
    super();
    y = 10;
} //end constructor

//...
} //end Subclass
```

The super keyword

The important thing to note in the above fragment is the statement containing the keyword **super** .

The **super** keyword has several uses in Java. As you might guess from the word, all of those uses have something to do with the superclass of the class in which the keyword is used.

Invoke the superclass constructor

When the **super** keyword (followed by a pair of matching parentheses) appears as the first executable statement in a constructor, this is an instruction to the runtime system to first call the constructor for the superclass, and then come back and finish executing the code in the constructor for the class to which the constructor belongs.

Call the *noarg* superclass constructor

If the parentheses following the **super** keyword are empty, this is an instruction to call the *noarg* constructor for the superclass.

Invoke a parameterized superclass constructor

If the parentheses are not empty, this is an instruction to find and call a parameterized constructor in the superclass whose formal arguments match the parameters in the parentheses.

Invoke the *noarg* superclass constructor by default

Here is an important point that is not illustrated above. If the first executable statement in your constructor is not an instruction to call the constructor for the superclass, an instruction to call the *noarg* constructor for the superclass will effectively be inserted into your constructor code before it is compiled.

Therefore, a constructor for the superclass is **always called** before the code in the constructor for your new class is executed.

You can choose the superclass constructor

The superclass constructor that is called may be the *noarg* constructor for the superclass, or you can force it to be a parameterized constructor by inserting something like

```
super(3,x,4.5);
```

as the first instruction in your constructor definition.

Always have a `noarg` constructor ...

Now you should understand why I told you in an earlier module that the classes you define should almost always have a `noarg` constructor, either the default `noarg` version, or a `noarg` version of your own design.

If your classes don't have a `noarg` constructor, then anyone who extends your classes will be required to put code in the constructor for their new class to call a parameterized constructor in your class.

In this program, the `super();` statement in the **Subclass** constructor causes the `noarg` constructor for the **Superclass** to be called. That `noarg` constructor is shown in the following code fragment.

```

class Superclass{
private int x = 1;

public Superclass(){
    x = 5;
} //end constructor

//...
} //end Superclass

```

Additional code

Beyond an exposure and explanation of the use of the `super` keyword to call the superclass constructor, this program plays a few games with initial values of instance variables just to see if you are alert to that sort of thing. However, none of that should be new to you, so I won't discuss it further here.

7.11.2 Preface

This module is part of a self-assessment test designed to help you determine how much you know about object-oriented programming using Java.

The test consists of a series of questions with answers and explanations of the answers.

The questions and the answers are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back.

I recommend that you open another copy of this document in a separate browser window and use the links to under Listings (p. 2528) to easily find and view the listings while you are reading about them.

7.11.3 Questions

7.11.3.1 Question 1 .

What output is produced by the program shown in Listing 1 (p. 2519) ?

- A. Compiler Error
- B. Runtime Error
- C. 33
- D. None of the above

Listing 1 . Listing for Question 1.

```

    public class Ap110{
    public static void main(
                String args[]){
        new Worker().doThis();
    }//end main()
}//end class Ap110

class Worker{
    private int data = 33;

    public void doThis(){
        new Helper().helpMe(this);
    }//end area()

    public String getData(){
        return data;
    }//end getData()
}// end class Worker

class Helper{
    public void helpMe(Worker param){
        System.out.println(
                param.getData());

    }//end helpMe()
}//end class Helper

```

Table 7.151

Answer and Explanation (p. 2541)

7.11.3.2 Question 2

What output is produced by the program shown in Listing 2 (p. 2520) ?

- A. Compiler Error
- B. Runtime Error
- C. 33
- D. None of the above.

Listing 2 . Listing for Question 2.

```
public class Ap111{
public static void main(
                String args[]){
    new Worker().doThis();
} //end main()
} //end class Ap111

class Worker{
    private int data = 33;

    public void doThis(){
        new Helper().helpMe(this);
    } //end area()

    public String getData(){
        return "" + data;
    } //end getData()
} // end class Worker

class Helper{
    public void helpMe(Worker param){
        System.out.println(
                param.getData());
    } //end helpMe()
} //end class Helper
```

Table 7.152

Answer and Explanation (p. 2539)

7.11.3.3 Question 3

What output is produced by the program shown in Listing 3 (p. 2521) ?

- A. Compiler Error
- B. Runtime Error
- C. 11
- D. 22
- E. 33
- F. 44
- G. None of the above.

Listing 3 . Listing for Question 3.

```
public class Ap112{
public static void main(
    String args[]){
    Worker obj1 = new Worker(11);
    Worker obj2 = new Worker(22);
    Worker obj3 = new Worker(33);
    Worker obj4 = new Worker(44);
    obj2.doThis();
} //end main()
} //end class Ap112

class Worker{
    private int data;

    public Worker(int data){
        this.data = data;
    } //end constructor

    public void doThis(){
        System.out.println(this);
    } //end area()

    public String toString(){
        return "" + data;
    } //end toString()
} // end class Worker
```

Answer and Explanation (p. 2537)

7.11.3.4 Question 4

What output is produced by the program shown in Listing 4 (p. 2523) ?

Note that 6.283185307179586 is a correct numeric value.

- A. Compiler Error
- B. Runtime Error
- C. 6.283185307179586
- D. None of the above.

Listing 4 . Listing for Question 4.

```

    public class Ap113{
    public static void main(
                String args[]){
        System.out.println(
                new Worker().twoPI);
    }//end main()
} //end class Ap113

class Worker{
    public static final double twoPI;

    public Worker(){
        twoPI = 2 * Math.PI;
    } //end constructor
} // end class Worker

```

7.11.6 Answers

7.11.6.1 Answer 10

C. 20 222.0 false — 5 222.0 true

7.11.6.1.1 Explanation 10

Four ways to initialize instance variables

There are at least four ways to establish initial values for instance variables (*you may be able to think of others*) :

1. Allow them to take on their default values.
2. Establish their values using initialization expressions.
3. Establish their values using hard-coded values within a constructor.
4. Establish their values using parameter values passed to parameterized constructors.

Using the first two ways

The following fragment illustrates the first two of those four ways.

```

class Worker{
private int myInt = 100;
private double myDouble = 222.0;
private boolean myBoolean;

//...

```

In the above fragment, the instance variables named **myInt** and **myDouble** receive their initial values from initialization expressions. In these two cases, the initialization expressions are very simple. They are simply literal expressions. However, they could be much more complex if needed.

The variable named **myBoolean** in the above fragment is allowed to take on its default value of false.

Replacing the default *noarg* constructor

The next fragment shows one of the two overloaded constructors in the class named **Worker** . This constructor is a replacement for the default *noarg* constructor.

```

class Worker{
private int myInt = 100;
private double myDouble = 222.0;
private boolean myBoolean;

public Worker(){
    myInt = 20;
} //end noarg constructor

//...

```

Using hard-coded values for initialization

This fragment illustrates the third of the four ways listed earlier to establish the initial value of the instance variables of an object of the class named **Worker** . In particular, this fragment assigns the hard-coded value 20 to the instance variable named **myInt** , thus overwriting the value of 100 previously established for that variable by an initialization expression.

*(All objects instantiated from the **Worker** class using this noarg constructor would have the same initial value for the variable named **myInt** .)*

Note, that this constructor does not disturb the initial values of the other two instance variables that were earlier established by an initialization expression, or by taking on the default value. Thus, the initial values of these two instance variables remain as they were immediately following the declaration of the variables.

Initial values using this *noarg* constructor

When an object of the **Worker** class is instantiated using this constructor and the values of the three instance variables are displayed, the results are as shown below:

20 222.0 false

The value of **myInt** is 20 as established by the constructor. The value of **myDouble** is 222.0 as established by the initialization expression, and the value of **myBoolean** is false as established by default.

Using constructor parameters for initialization

The next fragment shows the last of the four ways listed earlier for establishing the initial value of an instance variable.

```

public class Ap119{
public static void main(

```

```

        String args[]){
    //...
    new Worker(5,true).display();
    //...
} //end main()
} //end class Ap119

class Worker{
    private int myInt = 100;
    private double myDouble = 222.0;
    private boolean myBoolean;
    //...

    public Worker(int x, boolean y){
        myInt = x;
        myBoolean = y;
    } //end parameterized constructor

    //...
}

```

A parameterized constructor

The above fragment shows the second of two overloaded constructors for the class named **Worker**. This constructor uses two incoming parameter values to establish the values of two of the instance variables, overwriting whatever values may earlier have been established for those variables.

The above fragment uses this constructor to instantiate an object of the **Worker** class, assigning incoming parameter values of 5 and *true* to the instance variables named **myInt** and **myBoolean** respectively. This overwrites the value previously placed in the variable named **myInt** by the initialization expression. It also overwrites the default value previously placed in the instance variable named **myBoolean**.

*(Note that this constructor doesn't disturb the value for the instance variable named **myDouble** that was previously established through the use of an initialization expression.)*

Initial values using parameterized constructor

After instantiating the new object, this fragment causes the values of all three instance variables to be displayed. The result is:

```
5 222.0 true
```

As you can see, the values contained in the instance variables named **myInt** and **myBoolean** are the values of 5 and true placed there by the constructor, based on incoming parameter values. The value in the instance variable named **myDouble** is the value placed there by the initialization expression when the variable was declared.

Default initialization

If you don't take any steps to initialize instance variables, they will be automatically initialized. Numeric instance variables will be initialized with zero value for the type of variable involved. Instance variables of type **boolean** will be initialized to false. Instance variables of type **char** will be initialized to a Unicode value with all 16 bits set to zero. Reference variables will be initialized to null.

Initialization expression

If you provide an initialization expression for an instance variable, the value of the expression will overwrite the default value, and the value of the initialization expression will become the initial value for the instance variable.

Assignment in constructor code

If you use an assignment statement in a constructor to assign a value to an instance variable, that value will overwrite the value previously placed in the instance variable either by default, or by use of an

initialization expression. The constructor has the "last word" on the matter of initialization of instance variables.

Back to Question 10 (p. 2527)

7.11.6.2 Answer 9

A. Compiler Error

7.11.6.2.1 Explanation 9

The default constructor

When you define a class, you are not required to define a constructor for the class. If you do not define a constructor for the class, a default constructor that takes no arguments will be provided on your behalf. You can instantiate new objects of the class by applying the new operator to the default constructor as shown in the following code fragment from Question 8 (p. 2525) .

```
new Worker().display();
```

Behavior of the default constructor

As illustrated in Question 8 (p. 2525) , when you don't provide a constructor that purposely initializes the values of instance variables, or initialize them in some other manner, they will automatically be initialized to the default values described in Question 8 (p. 2525) .

Defining overloaded constructors

You can also define one or more overloaded constructors having different formal argument lists. The typical intended purpose of such constructors is to use incoming parameter values to initialize the values of instance variables in the new object.

A parameterized constructor

This is illustrated in the following code fragment. This fragment receives two incoming parameters and uses the values of those two parameters to initialize the values of two instance variables belonging to the new object.

```
class Worker{
private int myInt;
private boolean myBoolean;

public Worker(int x, boolean y){
    myInt = x;
    myBoolean = y;
} //end parameterized constructor

//display() omitted for brevity

} // end class Worker
```

If you define any constructors ...

However, there is a pitfall that you must never forget.

If you define any constructors in your new class, you must define all constructors that will ever be required for your new class.

If you define any constructors, the default constructor will no longer be provided automatically. Therefore, if a constructor that takes no arguments will ever be needed for your new class, and you define one or more parameterized constructors, you must define the *noarg* constructor when you define your class.

A parameterized constructor for Worker

The class named **Worker** in this program defines a constructor that receives two incoming parameters, one of type **int** and the other of type **boolean** . It uses those two incoming parameters to initialize two instance variables of the new object.

Oops!

However, it does not define a constructor with no arguments in the formal argument list (*commonly called a noarg constructor*) .

Calling the missing *noarg* constructor

The following code in the **main** method of the controlling class attempts to instantiate two objects of the **Worker** class. The first call of the constructor passes no parameters to the constructor. Thus, it requires a *noarg* constructor in order to instantiate the object.

```
public class Ap118{
public static void main(
    String args[]){
    new Worker().display();
    new Worker(5,true).display();
    System.out.println();
} //end main()
} //end class Ap118
```

A compiler error

Since there is no constructor defined in the **Worker** class with an empty formal argument list (*and the default version is not provided*) , the program produces the following compiler error.

```
Ap118.java:11: cannot resolve symbol
symbol   : constructor Worker
()
location: class Worker
    new Worker().display();
```

Back to Question 9 (p. 2526)

7.11.6.3 Answer 8

C. 0 0.0 false

7.11.6.3.1 Explanation 8

All instance variables are initialized to default values

All instance variables are automatically initialized to default values if the author of the class doesn't take explicit steps to cause them to be initialized to other values.

The default values

Numeric variables are automatically initialized to zero, while **boolean** variables are automatically initialized to false. Instance variables of type **char** are initialized to a Unicode value with all 16 bits set to zero. Reference variables are initialized to null.

Back to Question 8 (p. 2525)

7.11.6.4 Answer 7

A. Compiler Error

7.11.6.4.1 Explanation 7

Pushing the compiler beyond its limits

Compared to many programming environments, the Java compiler is very forgiving. However, there is a limit to how far even the Java compiler is willing to go to keep us out of trouble.

Initializing the value of a static variable

We can initialize the value of a **static** variable using an initialization expression as follows:

```
public static final MY_CONSTANT
    = initialization expression;
```

Important point

It is necessary for the compiler to be able to evaluate the initialization expression when it is encountered.

Illegal forward reference

This program attempts to use an initialization expression that makes use of the value of another **static** variable (*myPI*) that has not yet been established at that point in the compilation process. As a result, the program produces the following compiler error under JDK 1.3.

```
Ap116.java:18: illegal forward reference
    = 2 * myPI;
           ^
```

Reverse the order of the variable declarations

The problem can be resolved by reversing the order of the two **static** variable declarations in the following revised version of the program.

```
public class Ap116{
public static void main(
                    String args[]){
    System.out.println(Worker.twoPI);
} //end main()
} //end class Ap116

class Worker{
    public static final double myPI
                        = Math.PI;
    public static final double twoPI
                        = 2 * myPI;

} // end class Worker
```

This revised version of the program compiles and executes successfully.

Back to Question 7 (p. 2524)

7.11.6.5 Answer 6

C. 6.283185307179586

7.11.6.5.1 Explanation 6**Access via an object**

Question 5 (p. 2523) illustrated the fact that a **public static final** member variable of a class can be accessed via a reference to an object instantiated from the class.

Not the only way to access a *static* variable

However, that is not the only way in which **static** member variables can be accessed. More importantly, **public static** member variables of a class can be accessed simply by referring to the name of the class and the name of the member variable joined by a period.

*(Depending on other factors, it may not be necessary for the **static** variable to also be declared **public**, but that is the most general approach.)*

A *public static final* member variable

In this program, the **Worker** class declares and initializes a **public static final** member variable named **twoPI** as shown in the following fragment.

```
class Worker{
    public static final double twoPI
                          = 2 * Math.PI;
} // end class Worker
```

Accessing the *static* variable

The single statement in the **main** method of the controlling class accesses and displays the value of the **public static final** member variable named **twoPI** as shown in the following fragment.

```
public class Ap115{
    public static void main(
        String args[]){
        System.out.println(Worker.twoPI);
    } //end main()
} //end class Ap115
```

Objects share one copy of *static* variables

Basically, when a member variable is declared **static**, no matter how many objects are instantiated from a class (*including no objects at all*), they all share a single copy of the variable.

Sharing can be dangerous

This sharing of a common variable leads to the same kind of problems that have plagued programs that use **global** variables for years. If the code in any object changes the value of the **static** variable, it is changed insofar as all objects are concerned.

Should you use non-final *static* variables?

Most authors will probably agree that in most cases, you probably should not use **static** variables unless you also make them **final**.

*(There are some cases, such as counting the number of objects instantiated from a class, where a non-final **static** variable may be appropriate. However, the appropriate uses of non-final **static** variables are few and far between.)*

Should you also make *static* variables *public* ?

If you make your variables **static** and **final** , you will often also want to make them **public** so that they are easy to access. There are numerous examples in the standard Java class libraries where variables are declared as **public** , **static** , and **final** . This is the mechanism by which the class libraries create constants and make them available for easy access on a widespread basis.

The Color class

For example, the **Color** class defines a number of **public static final** variables containing the information that represents generic colors such as ORANGE, PINK, and MAGENTA. (*By convention, constants in Java are written with all upper-case characters, but that is not a technical requirement.*)

If you need generic colors and not custom colors, you can easily access and use these color values without the requirement to mix red, green, and blue to produce the desired color values.

Back to Question 6 (p. 2524)

7.11.6.6 Answer 5

C. 6.283185307179586

7.11.6.6.1 Explanation 5

A **public static final** variable

This program declares a **public static final** member variable named **twoPI** in the class named **Worker** , and properly initializes it when it is declared as shown in the following code fragment.

```
class Worker{ public static final double twoPI
              = 2 * Math.PI;
};// end class Worker
```

From that point forward in the program, this member variable named **twoPI** behaves like a constant, meaning that any code that attempts to change its value will cause a compiler error (*as in the program in Question 4 (p. 2521)*) ..

Accessing the static variable

The following single statement that appears in the **main** method of the controlling class instantiates a new object of the **Worker** class, accesses, and displays the **public static final** member variable named **twoPI** .

```
public static void main(
    String args[]){
System.out.println(
    new Worker().twoPI);
} }//end main()
```

(*Note for future discussion that the variable named **twoPI** is accessed via a reference to an object instantiated from the class named **Worker** .*)

This causes the **double** value 6.283185307179586 to be displayed on the standard output device.

Back to Question 5 (p. 2523)

7.11.6.7 Answer 4

A. Compiler Error

7.11.6.7.1 Explanation 4

A **final** variable

When a member variable of a class (*not a local variable*) is declared **final**, its value must be established when the variable is declared. This program attempts to assign a value to a **final** member variable after it has been declared, producing the following compiler error under JDK 1.3.

```
Ap113.java:20: cannot assign a value to
final variable twoPI
    twoPI = 2 * Math.PI;
```

Back to Question 4 (p. 2521)

7.11.6.8 Answer 3

D. 22

7.11.6.8.1 Explanation 3**Two uses of the *this* keyword**

This program illustrates two different uses of the **this** keyword.

Disambiguating a reference to a variable

Consider first the use of **this** that is shown in the following code fragment.

```
class Worker{
private int data;

public Worker(int data){
    this.data = data;
} //end constructor
```

Very common usage

The code in the above fragment is commonly used by many Java programmers. All aspiring Java programmers need to know how to read such code, even if they elect not to use it. In addition, understanding this code should enhance your overall understanding of the use and nature of the **this** keyword.

A parameterized constructor

The above fragment shows a parameterized constructor for the class named **Worker**. This constructor illustrates a situation where there is a local parameter named **data** that has the same name as an instance variable belonging to the object.

Casting a shadow

The existence of the local parameter named **data** casts a shadow on the instance variable having the same name, making it inaccessible by using its name alone.

(A local variable having the same name as an instance variable casts a similar shadow on the instance variable.)

In this shadowing circumstance, when the code in the constructor refers simply to the name **data**, it is referring to the local parameter having that name. In order for the code in the constructor to refer to the instance variable having the name **data**, it must refer to it as **this.data**.

In other words ...

In other words, **this.data** is a reference to an instance variable named **data** belonging to the object being constructed by the constructor (*this object*).

Not always necessary

You could always use this syntax to refer to an instance variable of the object being constructed if you wanted to. However, the use of this syntax is necessary only when a local parameter or variable has the same name as the instance variable and casts a shadow on the instance variable. When this is not the case, you can refer to the instance variable simply by referring to its name without the keyword **this** .

Finally, the main point ...

Now consider the main point of this program. The following fragment shows the **main** method of the controlling class for the application.

```
public class Ap112{
public static void main(
    String args[]){
    Worker obj1 = new Worker(11);
    Worker obj2 = new Worker(22);
    Worker obj3 = new Worker(33);
    Worker obj4 = new Worker(44);
    obj2.doThis();
} //end main()
} //end class Ap112
```

Four different objects of type Worker

The code in the above fragment instantiates four different objects from the class named **Worker** , passing a different value to the constructor for each object. Thus, individual instance variable in each of the four objects contain the **int** values 11, 22, 33, and 44 respectively.

Call an instance method on one object

Then the code in the **main** method calls the instance method named **doThis** on only one of the objects, which is the one referred to by the reference variable named **obj2** .

An overridden **toString** method of the **Worker** class is eventually called to return a **String** representation of the value stored in the instance variable named **data** for the purpose of displaying that value on the standard output device.

Overridden toString method

The next fragment shows the overridden **toString** method for the **Worker** class. As you can see, this overridden method constructs and returns a reference to a **String** representation of the **int** value stored in the instance variable named **data** . Thus, depending on which object the **toString** method is called on, different string values will be returned by the overridden method.

```
public String toString(){
return "" + data;
} //end toString()
} // end class Worker
```

Passing reference to this object to println method

The next fragment shows the **doThis** instance method belonging to each object instantiated from the **Worker** class. When this method is called on a specific object instantiated from the **Worker** class, it uses the **this** keyword to pass that specific object's reference to the **println** method. The **println** method uses that reference to call the **toString** method on that specific object. This, in turn causes a **String** representation of the value of the instance variable named **data** belonging to that specific object to be displayed.

```

    public void doThis(){
        System.out.println(this);
    }//end area()

```

The bottom line

In this program, the instance variable in the object referred to by **obj2** contains the value 22. The instance variables in the other three objects instantiated from the same class contain different values.

The bottom line is that the following statement in the **main** method causes the value 22 to be displayed on the standard output device. Along the way, the **this** keyword is used to cause the **println** method to get and display the value stored in a specific object, and to ignore three other objects that were instantiated from the same class.

```

obj2.doThis();

```

Back to Question 3 (p. 2520)

7.11.6.9 Answer 2

C. 33

7.11.6.9.1 Explanation 2

The **this** keyword

The key to an understanding of this program lies in an understanding of the single statement that appears in the method named **doThis**, as shown in the following fragment.

```

    public void doThis(){
        new Helper().helpMe(this);
    }//end area()

```

The keyword named **this** has several uses in Java, some of which are explicit, and some of which take place behind the scenes.

What do you need to know about the this keyword?

One of the uses of the keyword **this** is passing the implicit parameter in its entirety to another method.

That is exactly what this program does. But what is the implicit parameter named **this** anyway?

Every object holds a reference to itself

This implicit reference can be accessed using the keyword **this** in a non-static (*instance*) method belonging to the object. (*The implicit reference named **this** cannot be accessed from within a **static** method for reasons that won't be discussed here.*)

Calling an instance method

An instance method can only be called by referring to a specific object and joining that object's reference to the name of the instance method using a period as the joining operator. This is illustrated in the following statement, which calls the method named **doThis** on a reference to an object of the class named **Worker**

```

new Worker().doThis();

```

An anonymous object

The above statement creates an anonymous object of the class named **Worker** . (*An anonymous object is an object whose reference is not assigned to a named reference variable.*)

The code to the left of the period returns a reference to the new object. Then the code calls the instance method named **doThis** on the reference to the object.

Which object is *this* object?

When the code in the instance method named **doThis** refers to the keyword **this** , it is a reference to the specific object on which the **doThis** method was called. The statement in the following fragment passes a reference to that specific instance of the **Worker** class to a method named **helpMe** in a new object of the **Helper** class.

```
public void doThis(){
    new Helper().helpMe(this);
} //end area()
```

A little help here please

The **helpMe** method is shown in the following fragment.

```
class Helper{
public void helpMe(Worker param){
    System.out.println(
        param.getData());
} //end helpMe()
} //end class Helper
```

Using the incoming reference

The code in the **helpMe** method uses the incoming reference to the object of the **Worker** class to call the **getData** method on that object.

Thus code in the **helpMe** method is able to call a method in the object containing the method that called the **helpMe** method in the first place.

A callback scenario

When a method in one object calls a method in another object, passing **this** as a parameter, that makes it possible for the method receiving the parameter to make a callback to the object containing the method that passed **this** as a parameter.

The **getData** method returns a **String** representation of the **int** instance variable named **data** with a value of 33 that is contained in the object of the **Worker** class.

Display the value

The code in the **helpMe** method causes that string to be displayed on the computer screen.

And the main point is ...

Any number of objects can be instantiated from a given class. A given instance method can be called on any of those objects. When the code in such an instance method refers to **this** , it is referring to the specific object on which it was called, and is not referring to any of the many other objects that may have been instantiated from the same class.

Back to Question 2 (p. 2520)

7.11.6.10 Answer 1

A. Compiler Error

7.11.6.10.1 Explanation 1**A wakeup call**

The purpose of this question is simply to give you a wakeup call. The declaration for the method named `getData` indicates that the method returns a reference to an object of the class `String`. However, the code in the method attempts to return an `int`. The program produces the following compiler error under JDK 1.3.

```
found    : int
required: java.lang.String
return data;
```

7.12.2 Preface

This module is part of a self-assessment test designed to help you determine how much you know about object-oriented programming using Java.

The test consists of a series of questions with answers and explanations of the answers.

The questions and the answers are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back.

I recommend that you open another copy of this document in a separate browser window and use the links to under Listings (p. 2551) to easily find and view the listings while you are reading about them.

7.12.3 Questions**7.12.3.1 Question 1 .**

What output is produced by the program shown in Listing 1 (p. 2542) ?

- A. Compiler Error
- B. Runtime Error
- C. A
- D. None of the above.

7.12.6 Answers

7.12.6.1 Answer 10

D. A B

7.12.6.1.1 Explanation 10

Another illustration of simple polymorphic behavior

In this program, two classes named **A** and **B** extend the class named **Base** , each overriding the method named **test** to produce different behavior. *(Typically, overridden methods in different classes will produce different behavior, even though they have the same names.)*

Behavior appropriate for object on which method is called

In other words, the behavior of the method named **test** , when called on a reference to an object of type **A** , is different from the behavior of the method named **test** when called on a reference to an object of type **B** .

The method definitions

The definitions of the two classes named **A** and **B** , along with the two versions of the overridden method named **test** are shown in the following fragment.

```

class A extends Base{
public void test(){
    System.out.print("A ");
} //end test()
} //end class A

class B extends Base{
public void test(){
    System.out.print("B ");
} //end test()
} //end class B

```

Store a subclass object's reference as a superclass type

The program declares a reference variable of type **Base** , instantiates a new object of the class named **A** , and assigns that object's reference to the reference variable of type **Base** . Then it calls the method named **test** on that reference as shown in the following fragment.

```

Base myVar = new A();
myVar.test();

```

Polymorphic behavior applies

Simple polymorphic behavior causes the overridden version of the method named **test** , defined in the class named **A** , (as opposed to the versions defined in class **Base** or class **B**) to be executed. This causes the letter **A** followed by a space character to be displayed on the standard output device.

Store another subclass object's reference as superclass type

Then the program instantiates a new object from the class named **B** , and assigns that object's reference to the same reference variable, overwriting the reference previously stored there. (This causes the object whose reference was previously stored in the reference variable to become eligible for garbage collection in this case.)

Then the program calls the method named **test** on the reference as shown in the following fragment.

```

myVar = new B();
myVar.test();

```

Polymorphic behavior applies again

This time, simple polymorphic behavior causes the overridden version of the method named **test** , defined in the class named **B** , (as opposed to the versions defined in class **Base** or class **A**) to be executed. This causes the letter **B** followed by a space character to be displayed on the standard output device.

Once again, what is runtime polymorphic behavior?

With runtime polymorphic behavior, the method selected for execution is based, not on the type of the reference variable holding the reference to the object, but rather on the actual class from which the object was instantiated.

If the method was properly overridden, the behavior exhibited by the execution of the method is appropriate for an object of the class from which the object was instantiated.

Back to Question 10 (p. 2550)

7.12.6.2 Answer 9

D. A

7.12.6.2.1 Explanation 9

Compiles and executes successfully

This program compiles and executes successfully causing the version of the method named `test` , which is overridden in the class named `A` to be executed. That overridden method is shown in the following fragment.

```
class A extends Base{
    public void test(){
        System.out.print("A ");
    }//end test()
} //end class A
```

So, what is the issue here?

The purpose of this program is to determine if you understand polymorphic behavior and the role of downcasting. Consider the following fragment taken from the program in Question 8 (p. 2548) .

```
Base myVar = new A();
((A)myVar).test();
```

The downcast is redundant

As you learned in the discussion of Question 8 (p. 2548) , the downcast isn't required, and it has no impact on the behavior of the program in Question 8 (p. 2548) .

This program behaves exactly the same with the second statement in the above fragment replaced by the following statement, which does not contain a downcast.

```
myVar.test();
```

Again, you need to know when downcasting is required, when it isn't required, and to make use of that knowledge to downcast appropriately.

Back to Question 9 (p. 2549)

7.12.6.3 Answer 8

D. A

7.12.6.3.1 Explanation 8

Compiles and executes successfully

This program compiles and executes successfully causing the version of the method named `test` , which is overridden in the class named `A` to be executed. That overridden method is shown in the following fragment.

```

class A extends Base{
public void test(){
    System.out.print("A ");
} //end test()
} //end class A

```

So, what is the issue here?

The purpose of this program is to determine if you understand polymorphic behavior and the role of downcasting, as shown in the following fragment.

```

Base myVar = new A();
((A)myVar).test();

```

This would be a simple case of polymorphic behavior were it not for the downcast shown in the above fragment.

The downcast is redundant

Actually, the downcast was placed there to see if you could determine that it is redundant. It isn't required, and it has no impact on the behavior of this program. This program would behave exactly the same if the second statement in the above fragment were replaced with the following statement, which does not contain a downcast.

```

myVar.test();

```

You need to know when downcasting is required, when it isn't required, and to make use of that knowledge to downcast appropriately.

Back to Question 8 (p. 2548)

7.12.6.4 Answer 7

B. Runtime Error

7.12.6.4.1 Explanation 7

Storing a reference as a superclass type

You can store an object's reference in any reference variable whose declared type is a superclass of the actual class from which the object was instantiated.

May need to downcast later

Later on, when you attempt to make use of that reference, you may need to downcast it. Whether or not you will need to downcast will depend on what you attempt to do.

In order to call a method ...

For example, if you attempt to call a method on the reference, but that method is not defined in or inherited into the class of the reference variable, then you will need to downcast the reference in order to call the method on that reference.

Class Base defines method named test

This program defines a class named **Base** that defines a method named **test** .

Class A extends Base and overrides test

The program also defines a class named **A** that extends **Base** and overrides the method named **test** as shown in the following fragment.

```

class Base{
public void test(){
    System.out.print("Base ");};
}//end class Base

class A extends Base{
public void test(){
    System.out.print("A ");
} //end test()
} //end class A

```

A new object of the class **Base**

The program instantiates a new object of the class **Base** and stores a reference to that object in a reference variable of type **Base**, as shown in the following fragment.

```

Base myVar = new Base();
((A)myVar).test();

```

Could call **test** directly on the reference

Having done this, the program could call the method named **test** directly on the reference variable using a statement such as the following, which is not part of this program.

```

myVar.test();

```

This statement would cause the version of the method named **test** defined in the class named **Base** to be called, causing the word **Base** to appear on the standard output device.

This downcast is not allowed

However, this program attempts to cause the version of the method named **test** defined in the class named **A** to be called, by downcasting the reference to type **A** before calling the method named **test**. This is shown in the following fragment.

```

((A)myVar).test();

```

A runtime error occurs

This program compiles successfully. However, the downcast shown above causes the following runtime error to occur under JDK 1.3:

```

Exception in thread "main" java.lang.ClassCastException: Base
at Worker.doIt(Ap126.java:22)
at Ap126.main(Ap126.java:15)

```

What you can do

You can store an object's reference in a reference variable whose type is a superclass of the class from which the object was originally instantiated. Later, you can downcast the reference back to the type (*class*) from which the object was instantiated.

What you cannot do

However, you cannot downcast an object's reference to a subclass of the class from which the object was originally instantiated.

Unfortunately, the compiler is unable to detect an error of this type. The error doesn't become apparent until the exception is thrown at runtime.

Back to Question 7 (p. 2547)

7.12.6.5 Answer 6

C. Base

7.12.6.5.1 Explanation 6**Totally straightforward code**

This rather straightforward program instantiates an object of the class named **Base** and assigns that object's reference to a reference variable of the type **Base** as shown in the **following fragment** .

```
Base myVar = new Base();
myVar.test();
```

Then it calls the method named **test** on the reference variable.

Class Base defines the method named test

The class named **Base** contains a concrete definition of the method named **test** as shown in the following fragment. This is the method that is called by the code shown in the above fragment (p. 2557) .

```
class Base{
    public void test(){
        System.out.print("Base ");};
} //end class Base
```

Class A is just a smokescreen

The fact that the class named **A** extends the class named **Base** , and overrides the method named **test** , as shown in the following fragment, is of absolutely no consequence in the behavior of this program. Hopefully you understand why this is so. If not, then you still have a great deal of studying to do on Java inheritance.

```
class A extends Base{
    public void test(){
        System.out.print("A ");
    } //end test()
} //end class A
```

Back to Question 6 (p. 2546)

7.12.6.6 Answer 5

A. Compiler Error

7.12.6.6.1 Explanation 5

Cannot instantiate an abstract class

This program defines an **abstract** class named **Base** . Then it violates one of the rules regarding **abstract** classes, by attempting to instantiate an object of the **abstract** class as shown in the following code fragment.

```
Base myVar = new Base();
```

The program produces the following compiler error under JDK 1.3:

```
Ap124.java:19: Base is abstract; cannot be instantiated
Base myVar = new Base();
```

Back to Question 5 (p. 2545)

7.12.6.7 Answer 4

C. A

7.12.6.7.1 Explanation 4

An abstract class with an abstract method

This program illustrates the use of an **abstract** class containing an **abstract** method to achieve *polymorphic behavior* .

The following code fragment shows an **abstract** class named **Base** that contains an **abstract** method named **test** .

```
abstract class Base{
    abstract public void test();
} //end class Base
```

Extending abstract class and overriding abstract method

The class named **A** , shown in the following fragment extends the **abstract** class named **Base** and overrides the **abstract** method named **test** .

```
class A extends Base{
    public void test(){
        System.out.print("A ");
    } //end test()
} //end class A
```

Can store a subclass reference as a superclass type

Because the class named **A** extends the class named **Base**, a reference to an object instantiated from the class named **A** can be stored in a reference variable of the declared type **Base**. No cast is required in this case.

Polymorphic behavior

Furthermore, because the class named **Base** contains the method named **test**, (as an **abstract method**), when the method named **test** is called on a reference to an object of the class named **A**, stored in a reference variable of type **Base**, the *overridden* version of the method as defined in the class named **A** will actually be called. This is polymorphic behavior.

*(Note, however, that this example does little to illustrate the power of polymorphic behavior because only one class extends the class named **Base** and only one version of the abstract method named **test** exists. Thus, the system is not required to select among two or more overridden versions of the method named **test**.)*

The important code

The following code fragment shows the instantiation of an object of the class named **A** and the assignment of that object's reference to a reference variable of type **Base**. Then the fragment calls the method named **test** on the reference variable.

```
Base myVar = new A();
myVar.test();
```

This causes the overridden version of the method named **test**, shown in the following fragment, to be called, which causes the letter **A** to be displayed on the standard output device.

```
public void test(){
    System.out.print("A ");
} //end test()
```

Back to Question 4 (p. 2544)

7.12.6.8 Answer 3

A. Compiler Error

7.12.6.8.1 Explanation 3**Classes can be final or abstract, but not both**

A class in Java may be declared **final**. A class may also be declared **abstract**. A class cannot be declared both **final** and **abstract**.

Behavior of final and abstract classes

A class that is declared **final** cannot be extended. A class that is declared **abstract** cannot be instantiated. Therefore, it must be extended to be useful.

An **abstract** class is normally intended to be extended.

Methods can be final or abstract, but not both

A method in Java may be declared **final**. A method may also be declared **abstract**. However, a method cannot be declared both **final** and **abstract**.

Behavior of final and abstract methods

A method that is declared **final** cannot be overridden. A method that is declared **abstract** must be overridden to be useful.

An **abstract** method doesn't have a body.

Abstract classes and methods

A class that contains an **abstract** method must itself be declared **abstract** . However, an **abstract** class is not required to contain **abstract** methods.

Failed to declare the class abstract

In this program, the class named **Base** contains an **abstract** method named **test** , but the class is not declared **abstract** as required.

```
class Base{
    abstract public void test();
} //end class Base
```

Therefore, the program produces the following compiler error under JDK 1.3:

```
Ap122.java:24: Base should be declared abstract;
it does not define test in Base
class Base{
```

Back to Question 3 (p. 2543)

7.12.6.9 Answer 2

C. A

7.12.6.9.1 Explanation 2

If you missed this ...

If you missed this question, you didn't pay attention to the explanation for Question 1 (p. 2542) .

Define a method in a subclass

This program defines a subclass named **A** that extends a superclass named **Base** . A method named **test** is defined in the subclass named **A** but is not defined in any superclass of the class named **A** .

Store a reference as a superclass type

The program declares a reference variable of the superclass type, and stores a reference to an object of the subclass in that reference variable as shown in the following code fragment.

```
Base myVar = new A();
```

Downcast and call the method

Then the program calls the method named **test** on the reference stored as the superclass type, as shown in the following fragment.

```
((A)myVar).test();
```

Unlike the program in Question 1 (p. 2542) , the reference is downcast to the true type of the object before calling the method named `test` . As a result, this program does not produce a compiler error.

Why is the cast required?

As explained in Question 1 (p. 2542) , it is allowable to store a reference to a subclass object in a variable of a superclass type. Also, as explained in Question 1 (p. 2542) , it is not allowable to directly call, on that superclass reference, a method of the subclass object that is not defined in or inherited into the superclass.

However, such a call is allowable if the programmer purposely downcasts the reference to the true type of the object before calling the method.

Back to Question 2 (p. 2542)

7.12.6.10 Answer 1

A. Compiler Error

7.12.6.10.1 Explanation 1

Define a method in a subclass

This program defines a subclass named `A` that extends a superclass named `Base` . A method named `test` , is defined in the subclass named `A` , which is not defined in any superclass of the class named `A` .

Store a reference as superclass type

The program declares a reference variable of the superclass type, and stores a reference to an object of the subclass in that reference variable as shown in the following code fragment.

```
Base myVar = new A();
```

Note that no cast is required to store a reference to a subclass object in a reference variable of a superclass type. The required type conversion happens automatically in this case.

Call a method on the reference

Then the program attempts to call the method named `test` on the reference stored as the superclass type, as shown in the following fragment. This produces a compiler error.

```
myVar.test();
```

The reason for the error

It is allowable to store a reference to a subclass object in a variable of a superclass type. However, it is not allowable to directly call, (*on that superclass reference*) , a method of the subclass object that is not defined in or inherited into the superclass.

The following error message is produced by JDK 1.3.

```
Ap120.java:18: cannot resolve symbol
symbol  : method test ()
location: class Base
    myVar.test();
```

The solution is ...

This error can be avoided by casting the reference to type `A` before calling the method as shown below:

```
((A)myVar).test();
```

- Answers (p. 2577)

7.13.2 Preface

This module is part of a self-assessment test designed to help you determine how much you know about object-oriented programming using Java.

The test consists of a series of questions with answers and explanations of the answers.

The questions and the answers are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back.

I recommend that you open another copy of this document in a separate browser window and use the links to under Listings (p. 2577) to easily find and view the listings while you are reading about them.

7.13.3 Questions

7.13.3.1 Question 1 .

What output is produced by the program shown in Listing 1 (p. 2563) ?

- A. Compiler Error
- B. Runtime Error
- C. Base A-intfcMethod
- D. None of the above.

²¹This content is available online at <<http://cnx.org/content/m45303/1.5/>>.

Listing 1 . Listing for Question 1.

```

    public class Ap131{
    public static void main(
                String args[]){
        new Worker().doIt();
    }//end main()
}//end class Ap131

class Worker{
    void doIt(){
        Base myVar1 = new Base();
        myVar1.inherMethod();
        X myVar2 = new A();
        myVar2.intfcMethod();

        System.out.println("");
    }//end doIt()
}// end class Worker

class Base{
    public void inherMethod(){
        System.out.print("Base ");
    }//end inherMethod()
}//end class Base

class A extends Base{
    public void inherMethod(){
        System.out.print(
                " A-inherMethod ");
    }//end inherMethod()

    public void intfcMethod(){
        System.out.print("A-intfcMethod ");
    }//end intfcMethod()
}//end class A

interface X{
    public void intfcMethod();
}//end X

```

7.13.3.2 Question 2

What output is produced by the program shown in Listing 2 (p. 2564) ?

- A. Compiler Error

- B. Runtime Error
- C. A-inherMethod A-intfcMethod
- D. None of the above.

Listing 2 . Listing for Question 2.

```

    public class Ap132{
    public static void main(
        String args[]){
        new Worker().doIt();
    }//end main()
}//end class Ap132

class Worker{
    void doIt(){
        Base myVar1 = new Base();
        myVar1.inherMethod();
        Base myVar2 = new A();
        myVar2.intfcMethod();

        System.out.println("");
    }//end doIt()
}// end class Worker

class Base{
    public void inherMethod(){
        System.out.print("Base ");
    }//end inherMethod()
}//end class Base

class A extends Base implements X{
    public void inherMethod(){
        System.out.print(
            " A-inherMethod ");
    }//end inherMethod()

    public void intfcMethod(){
        System.out.print("A-intfcMethod ");
    }//end intfcMethod()
}//end class A

interface X{
    public void intfcMethod();
}//end X

```

    public void intfMethodX();
} //end X

```

Answer and Explanation (p. 2585)

7.13.3.6 Question 6

What output is produced by the program shown in Listing 6 (p. 2569) ?

- A. Compiler Error
- B. Runtime Error
- C. A-intfMethodX B-intfMethodX
- D. None of the above.

Listing 6 . Listing for Question 6.

```

    public class Ap136{
    public static void main(
                                String args[]){
        new Worker().doIt();
    } //end main()
} //end class Ap136

class Worker{
    void doIt(){
        Object[] myArray = new Object[2];
        myArray[0] = new A();
        myArray[1] = new B();

        for(int i=0;i<myArray.length;i++){
            myArray[i].intfMethodX();
        } //end for loop

        System.out.println("");
    } //end doIt()
} // end class Worker

class Base{
    public void inherMethod(){
        System.out.print("Base ");
    } //end inherMethod()
} //end class Base

class A extends Base implements X{
    public void inherMethod(){
        System.out.print(
            " A-inherMethod ");
    } //end inherMethod()

    public void intfMethodX(){

```

```

        System.out.print(
            "A-intfcMethodX ");
    }//end intfcMethodX()
} //end class A

class B extends Base implements X{
    public void inherMethod(){
        System.out.print(
            " B-inherMethod ");
    } //end inherMethod()

    public void intfcMethodX(){
        System.out.print(
            "B-intfcMethodX ");
    } //end intfcMethodX()
} //end class B

interface X{
    public void intfcMethodX();
} //end X

```

Answer and Explanation (p. 2582)

7.13.3.7 Question 7

What output is produced by the program shown in Listing 7 (p. 2570) ?

- A. Compiler Error
- B. Runtime Error
- C. A-intfcMethodX B-intfcMethodX
- D. None of the above.

Listing 7 . Listing for Question 7.

```

    public class Ap137{
    public static void main(
        String args[]){
        new Worker().doIt();
    } //end main()
} //end class Ap137

class Worker{
    void doIt(){
        Object[] myArray = new Object[2];
        myArray[0] = new A();
        myArray[1] = new B();

        for(int i=0;i<myArray.length;i++){
            ((X)myArray[i]).intfcMethodX();
        } //end for loop

        System.out.println("");
    } //end doIt()
}

```

```

} // end class Worker

class Base{
    public void inHerMethod(){
        System.out.print("Base ");
    } //end inHerMethod()
} //end class Base

class A extends Base implements X{
    public void inHerMethod(){
        System.out.print(
            " A-inHerMethod ");
    } //end inHerMethod()

    public void intfcMethodX(){
        System.out.print(
            "A-intfcMethodX ");
    } //end intfcMethodX()
} //end class A

class B extends Base implements X{
    public void inHerMethod(){
        System.out.print(
            " B-inHerMethod ");
    } //end inHerMethod()

    public void intfcMethodX(){
        System.out.print(
            "B-intfcMethodX ");
    } //end intfcMethodX()
} //end class B

interface X{
    public void intfcMethodX();
} //end X

```

Answer and Explanation (p. 2581)

7.13.3.8 Question 8

What output is produced by the program shown in Listing 8 (p. 2571) ?

- A. Compiler Error
- B. Runtime Error
- C. A-intfcMethodX B-intfcMethodX
- D. None of the above.

Listing 8 . Listing for Question 8.

```

public class Ap138{
public static void main(
                String args[]){
    new Worker().doIt();

```

```

    }//end main()
} //end class Ap138

class Worker{
    void doIt(){
        X[] myArray = new X[2];
        myArray[0] = new A();
        myArray[1] = new B();

        for(int i=0;i<myArray.length;i++){
            myArray[i].intfcMethodX();
        } //end for loop

        System.out.println("");
    } //end doIt()
} // end class Worker

class Base{
    public void inherMethod(){
        System.out.print("Base ");
    } //end inherMethod()
} //end class Base

class A extends Base implements X{
    public void inherMethod(){
        System.out.print(
            " A-inherMethod ");
    } //end inherMethod()

    public void intfcMethodX(){
        System.out.print(
            "A-intfcMethodX ");
    } //end intfcMethodX()
} //end class A

class B extends Base implements X{
    public void inherMethod(){
        System.out.print(
            " B-inherMethod ");
    } //end inherMethod()

    public void intfcMethodX(){
        System.out.print(
            "B-intfcMethodX ");
    } //end intfcMethodX()
} //end class B

interface X{
    public void intfcMethodX();
} //end X

```

Answer and Explanation (p. 2580)

7.13.3.9 Question 9

What output is produced by the program shown in Listing 9 (p. 2574) ?

- A. Compiler Error
- B. Runtime Error
- C. Base A B
- D. None of the above.

Listing 9 . Listing for Question 9.

```

    public class Ap139{
    public static void main(
                String args[]){
        new Worker().doIt();
    }//end main()
} //end class Ap139

class Worker{
    void doIt(){
        Base myVar = new Base();
        myVar.test();
        myVar = new A();
        myVar.test();
        myVar = new B();
        myVar.test();
        System.out.println("");
    } //end doIt()
} // end class Worker

class Base{
    public void test(){
        System.out.print("Base ");
    } //end test()
} //end class Base

class A extends Base implements X,Y{
    public void test(){
        System.out.print("A ");
    } //end test()
} //end class A

class B extends Base implements X,Y{
    public void test(){
        System.out.print("B ");
    } //end test()
} //end class B

interface X{
    public void test();
} //end X

interface Y{
    public void test();
} //end Y

```

Table 7.175

Answer and Explanation (p. 2578)

7.13.3.10 Question 10

What output is produced by the program shown in Listing 10 (p. 2576) ?

- A. Compiler Error
- B. Runtime Error
- C. Base A B B
- D. None of the above.

Listing 10 . Listing for Question 10.

```
public class Ap140{
public static void main(
                String args[]){
    new Worker().doIt();
} //end main()
} //end class Ap140

class Worker{
    void doIt(){
        Base myVar1 = new Base();
        myVar1.test();
        myVar1 = new A();
        myVar1.test();
        myVar1 = new B();
        myVar1.test();

        X myVar2 = (X)myVar1;
        myVar2.test();

        System.out.println("");
    } //end doIt()
} // end class Worker

class Base{
    public void test(){
        System.out.print("Base ");
    } //end test()
} //end class Base

class A extends Base implements X,Y{
    public void test(){
        System.out.print("A ");
    } //end test()
} //end class A

class B extends Base implements X,Y{
    public void test(){
        System.out.print("B ");
    } //end test()
} //end class B

interface X{
    public void test();
} //end X

interface Y{
    public void test();
} //end Y
```

7.13.6 Answers

7.13.6.1 Answer 10

C. Base A B B

7.13.6.1.1 Explanation 10

Expansion of the program from Question 9 (p. 2573)

The class and interface definitions for the classes and interfaces named **Base** , **A** , **B** , **X** , and **Y** are the same as in Question 9 (p. 2573) .

Call the test method differently

However, the call of the method named **test** in the object instantiated from the class named **B** is somewhat different. The difference is identified by the code in the following fragment.

```

    void doIt(){
    Base myVar1 = new Base();
    myVar1.test();
    myVar1 = new A();
    myVar1.test();
    myVar1 = new B();
    myVar1.test();

    X myVar2 = (X)myVar1;
    myVar2.test();

    System.out.println("");
} //end doIt()

```

Calling test method on Base-type reference

In Question 9 (p. 2573) , and in the above code fragment as well, the method named **test** was called on each of the objects using a reference stored in a reference variable of type **Base** .

Calling the overridden version of test method

This might be thought of as calling the overridden version of the method, through polymorphism, without regard for anything having to do with the interfaces.

Calling test method on interface-type reference

Then the code shown above calls the same method named **test** on one of the same objects using a reference variable of the interface type **X** .

Only one test method in each object

Keep in mind that each object defines only one method named **test** . This single method serves the dual purpose of overriding the method having the same signature from the superclass, and implementing a method with the same signature declared in each of the interfaces.

Implementing the interface method

Perhaps when the same method is called using a reference variable of the interface type, it might be thought of as implementing the interface method rather than overriding the method defined in the superclass. You can be the judge of that.

The same method is called regardless of reference type

In any event, in this program, the same method is called whether it is called using a reference variable of the superclass type, or using a reference variable of the interface type.

Illustrates the behavior of signature collisions

The purpose of this and Question 9 (p. 2573) is not necessarily to illustrate a useful inheritance and implementation construct. Rather, these two questions are intended to illustrate the behavior of Java for the case of duplicated superclass and interface method signatures.

Back to Question 10 (p. 2575)

7.13.6.2 Answer 9

C. Base A B

7.13.6.2.1 Explanation 9**A question regarding signature collisions**

The question often arises in my classroom as to what will happen if a class inherits a method with a given signature and also implements one or more interfaces that declare a method with an identical signature.

The answer

The answer is that nothing bad happens, as long as the class provides a concrete definition for a method having that signature.

Only one method definition is allowed

Of course, only one definition can be provided for any given method signature, so that definition must satisfy the needs of overriding the inherited method as well as the needs of implementing the interfaces.

An example of signature collisions

The following fragment defines a class named `Base` that defines a method named `test`. The code also defines two interfaces named `X` and `Y`, each of which declares a method named `test` with an identical signature.

```

class Base{
public void test(){
    System.out.print("Base ");
} //end test()
} //end class Base

interface X{
    public void test();
} //end X

interface Y{
    public void test();
} //end Y

class A extends Base implements X,Y{
    public void test(){
        System.out.print("A ");
    } //end test()
} //end class A

```

Classes A and B extend Base and implement X and Y

The code in the following fragment defines two classes, named `A` and `B`, each of which extends `Base`, and each of which implements both interfaces `X` and `Y`. Each class provides a concrete definition for the method named `test`, with each class providing a different definition.

```

class A extends Base implements X,Y{
public void test(){
    System.out.print("A ");
} //end test()
} //end class A

class B extends Base implements X,Y{
    public void test(){

```

```

        System.out.print("B ");
    }//end test()
} //end class B

```

Override inherited method and define interface method

Each of the methods named `test` in the above fragment serves not only to override the method inherited from the class named `Base`, but also to satisfy the requirement to define the methods declared in the implemented interfaces named `X` and `Y`. (*This can also be thought of as overriding an inherited abstract method from an interface.*)

Store object's references as type `Base` and call `test` method

Finally, the code in the following fragment declares a reference variable of the type `Base`. Objects respectively of the classes `Base`, `A`, and `B` are instantiated and stored in the reference variable. Then the method named `test` is called on each of the references in turn.

```

    void doIt(){
    Base myVar = new Base();
    myVar.test();
    myVar = new A();
    myVar.test();
    myVar = new B();
    myVar.test();
    System.out.println("");
    } //end doIt()
} // end class Worker

```

As you probably expected, this causes the following text to appear on the screen:

```
Base A B
```

Back to Question 9 (p. 2573)

7.13.6.3 Answer 8

C. A-intfcMethodX B-intfcMethodX

7.13.6.3.1 Explanation 8

Similar to previous two programs

This program is very similar to the programs in Question 6 (p. 2569) and Question 7 (p. 2570). The program in Question 6 (p. 2569) exposed a specific type mismatch problem. The program in Question 7 (p. 2570) provided one solution to the problem.

A different solution

The following fragment illustrates a different solution to the problem.

```

    void doIt(){
    X[] myArray = new X[2];
    myArray[0] = new A();

```

```

myArray[1] = new B();

for(int i=0;i<myArray.length;i++){
    myArray[i].intfcMethodX();
} //end for loop

System.out.println("");
} //end doIt()

```

An array object of the interface type

In this case, rather than to declare the array object to be of type `Object`, the array is declared to be of the interface type `X`.

This is a less generic container than the one declared to be of type `Object`. Only references to objects instantiated from classes that implement the `X` interface, or objects instantiated from subclasses of those classes can be stored in the container. However, this is often adequate.

What methods can be called?

Since the references are stored as the interface type, any method declared in or inherited into the interface can be called on the references stored in the container. Of course, the objects referred to by those references must provide concrete definitions of those methods or the program won't compile.

(Although it isn't implicitly obvious, it is also possible to call any of the eleven methods defined in the `Object` class on an object's reference being stored as an interface type. Those eleven methods can be called on any object, including array objects, regardless of how the references are stored.)

Not the standard approach

If you are defining your own container, this is a satisfactory approach to implementation of the observer design pattern. However, you cannot use this approach when using containers from the standard collections framework, because those containers are designed to always store references as the generic type `Object`. In those cases, the casting solution of Question 7 (p. 2570) (or the use of generics) is required.

Back to Question 8 (p. 2571)

7.13.6.4 Answer 7

C. A-intfcMethodX B-intfcMethodX

7.13.6.4.1 Explanation 7

The correct use of an interface

This program illustrates the correct use of an interface. It uses a cast of the interface type in the following fragment to resolve the problem that was discussed at length in Question 6 (p. 2569) earlier.

```

void doIt(){
    Object[] myArray = new Object[2];
    myArray[0] = new A();
    myArray[1] = new B();

    for(int i=0;i<myArray.length;i++){
        ((X)myArray[i]).intfcMethodX();
    } //end for loop

    System.out.println("");
} //end doIt()

```

Back to Question 7 (p. 2570)

7.13.6.5 Answer 6

A. Compiler Error

7.13.6.5.1 Explanation 6

What is a container?

The word container is often used in Java, with at least two different meanings. One meaning is to refer to the type of an object that is instantiated from a subclass of the class named **Container**. In that case, the object can be considered to be of type **Container**, and typically appears in a graphical user interface (*GUI*). That is not the usage of the word in the explanation of this program.

A more generic meaning

In this explanation, the word container has a more generic meaning. It is common to store a collection of object references in some sort of Java container, such as an array object or a **Vector** object. In fact, there is a complete collections framework provided to facilitate that sort of thing (*Vector is one of the concrete classes in the Java Collections Framework*).

Storing references as type Object

It is also common to declare the type of references stored in the container to be of the class **Object**. Because **Object** is a completely generic type, this means that a reference to any object instantiated from any class (*or any array object*) can be stored in the container. The standard containers such as **Vector** and **Hashtable** take this approach.

(Note that this topic became a little more complicated with the release of generics in jdk version 1.5.)

A class named Base and an interface named X

In a manner similar to several previous programs, this program defines a class named **Base** and an interface named **X** as shown in the following fragment.

```
class Base{
    public void inherMethod(){
        System.out.print("Base ");
    }//end inherMethod()
}//end class Base

interface X{
    public void intfMethodX();
}//end X
```

Classes A and B extend Base and implement X

Also similar to previous programs, this program defines two classes named **A** and **B**. Each of these classes extends the class named **Base** and implements the interface named **X**, as shown in the next fragment.

```
class A extends Base implements X{
    public void inherMethod(){
        System.out.print(
            " A-inherMethod ");
    }//end inherMethod()

    public void intfMethodX(){
        System.out.print(
```

```

        "A-intfcMethodX ");
    }//end intfcMethodX()
} //end class A

class B extends Base implements X{
    public void inherMethod(){
        System.out.print(
            " B-inherMethod ");
    } //end inherMethod()

    public void intfcMethodX(){
        System.out.print(
            "B-intfcMethodX ");
    } //end intfcMethodX()
} //end class B

```

Concrete definitions of the interface method

As before, these methods provide concrete definitions of the method named `intfcMethodX`, which is declared in the interface named `X`.

An array of references of type `Object`

The interesting portion of this program begins in the following fragment, which instantiates and populates a two-element array object (*container*) of type `Object`. (*In the sense of this discussion, an array object is a container, albeit a very simple one.*)

```

    void doIt(){
        Object[] myArray = new Object[2];
        myArray[0] = new A();
        myArray[1] = new B();
    }

```

Store object references of type `A` and `B` as type `Object`

Because the container is declared to be of type `Object`, references to objects instantiated from any class can be stored in the container. The code in the above fragment instantiates two objects, (*one of class `A` and the other of class `B`*), and stores the two object's references in the container.

Cannot call interface method as type `Object`

The code in the `for` loop in the next fragment attempts to call the method named `intfcMethodX` on each of the two objects whose references are stored in the elements of the array.

```

        for(int i=0;i<myArray.length;i++){
            myArray[i].intfcMethodX();
        } //end for loop

        System.out.println("");
    } //end doIt()

```

This produces the following compiler error under JDK 1.3:

```

Ap136.java:24: cannot resolve symbol
symbol   : method intfMethodX ()
location: class java.lang.Object

```

```
myArray[i].intfMethodX();
```

What methods can you call as type **Object**?

It is allowable to store the reference to an object instantiated from any class in a container of the type **Object** . However, the only methods that can be directly called (*without a cast and not using generics*) on that reference are the following eleven methods. These methods are defined in the class named **Object** :

- **clone** ()
- **equals**(Object obj)
- **finalize**()
- **getClass**()
- **hashCode**()
- **notify**()
- **notifyAll**()
- **toString**()
- **wait**()
- **wait**(long timeout)
- **wait**(long timeout,int nanos)

Overridden methods

Some, (*but not all*) , of the methods in the above list are defined with default behavior in the **Object** class, and are meant to be overridden in new classes that you define. This includes the methods named **equals** and **toString** .

Some of the methods in the above list, such as **getClass** , are simply utility methods, which are not meant to be overridden.

Polymorphic behavior applies

If you call one of these methods on an object's reference (*being stored as type Object*) , polymorphic behavior will apply. The version of the method overridden in, or inherited into, the class from which the object was instantiated will be identified and executed.

Otherwise, a cast is required

In order to call any method other than one of the eleven methods in the above list (p. 2584) , (*on an object's reference being stored as type Object without using generics*) , you must cast the reference to some other type.

Casting to an interface type

The exact manner in which you write the cast will differ from one situation to the next. In this case, the problem can be resolved by rewriting the program using the interface cast shown in the following fragment.

```

void doIt(){
Object[] myArray = new Object[2];
myArray[0] = new A();
myArray[1] = new B();

for(int i=0;i<myArray.length;i++){
    ((X)myArray[i]).intfMethodX();
} //end for loop

```

```

    System.out.println("");
} //end doIt()

```

The observer design pattern

By implementing an interface, and using a cast such as this, you can store references to many different objects, of many different actual types, each of which implements the same interface, but which have no required superclass-subclass relationship, in the same container. Then, when needed, you can call the interface methods on any of the objects whose references are stored in the container.

This is a commonly used design pattern in Java, often referred to as the observer design pattern.

Registration of observers

With this design pattern, none, one, or more observer objects, (*which implement a common observer interface*) are registered on an observable object. This means references to the observer objects are stored in a container by the observable object.

Making a callback

When the observable object determines that some interesting event has occurred, the observable object calls a specific interface method on each of the observer objects whose references are stored in the container.

The observer objects execute whatever behavior they were designed to execute as a result of having been notified of the event.

The model-view-control (MVC) paradigm

In fact, there is a class named **Observable** and an interface named **Observer** in the standard Java library. The purpose of these class and interface definitions is to make it easy to implement the observer design pattern.

(The Observer interface and the Observable class are often used to implement a programming style commonly referred to as the MVC paradigm.)

Delegation event model, bound properties of Beans, etc.

Java also provides other tools for implementing the observer design pattern under more specific circumstances, such as the Delegation Event Model, and in conjunction with bound and constrained properties in JavaBeans Components.

Back to Question 6 (p. 2569)

7.13.6.6 Answer 5

C. A-intfcMethodX B-intfcMethodX

7.13.6.6.1 Explanation 5

More substantive use of an interface

This program illustrates a more substantive use of the interface than was the case in the previous programs.

The class named Base

The program defines a class named **Base** as shown in the following fragment.

```

class Base{
public void inherMethod(){
    System.out.print("Base ");
} //end inherMethod()
} //end class Base

```

The interface named **X**

The program also defines an interface named **X** as shown in the next fragment. Note that this interface declares a method named **intfcMethodX** .

```
interface X{
    public void intfcMethodX();
} //end X
```

Class **A** extends **Base** and implements **X**

The next fragment shows the definition of a class named **A** that extends **Base** and implements **X** .

```
class A extends Base implements X{
    public void inherMethod(){
        System.out.print(
            " A-inherMethod ");
    } //end inherMethod()

    public void intfcMethodX(){
        System.out.print(
            "A-intfcMethodX ");
    } //end intfcMethodX()
} //end class A
```

Defining interface method

Because the class named **A** implements the interface named **X** , it must provide a concrete definition of all the methods declared in **X** .

In this case, there is only one such method. That method is named **intfcMethodX** . A concrete definition for the method is provided in the class named **A** .

Class **B** also extends **Base** and implements **X**

The next fragment shows the definition of another class (named **B**), which also extends **Base** and implements **X** .

```
class B extends Base implements X{
    public void inherMethod(){
        System.out.print(
            " B-inherMethod ");
    } //end inherMethod()

    public void intfcMethodX(){
        System.out.print(
            "B-intfcMethodX ");
    } //end intfcMethodX()
} //end class B
```

Defining the interface method

Because this class also implements **X** , it must also provide a concrete definition of the method named **intfcMethodX** .

Different behavior for interface method

However (*and this is extremely important*), there is no requirement for this definition of the method to match the definition in the class named **A**, or to match the definition in any other class that implements **X**.

Only the method signature for the method named **intfcMethodX** is necessarily common among all the classes that implement the interface.

The definition of the method named **intfcMethodX** in the class named **A** is different from the definition of the method having the same name in the class named **B**.

The interesting behavior

The interesting behavior of this program is illustrated by the code in the following fragment.

```

        void doIt(){
        X myVar1 = new A();
        myVar1.intfcMethodX();
        X myVar2 = new B();
        myVar2.intfcMethodX();

        System.out.println("");
    }//end doIt()

```

Store object's references as interface type X

The code in the above fragment causes one object to be instantiated from the class named **A**, and another object to be instantiated from the class named **B**.

The two object's references are stored in two different reference variables, each declared to be of the type of the interface **X**.

Call the interface method on each reference

A method named **intfcMethodX** is called on each of the reference variables. Despite the fact that both object's references are stored as type **X**, the system selects and calls the appropriate method, (*as defined by the class from which each object was instantiated*), on each of the objects. This causes the following text to appear on the screen:

```
A-intfcMethodX B-intfcMethodX
```

No subclass-superclass relationship exists

Thus, the use of an interface makes it possible to call methods having the same signatures on objects instantiated from different classes, without any requirement for a subclass-superclass relationship to exist among the classes involved.

In this case, the only subclass-superclass relationship between the classes named **A** and **B** was that they were both subclasses of the same superclass. Even that relationship was established for convenience, and was not a requirement.

Different behavior of interface methods

The methods having the same signature, (*declared in the common interface, and defined in the classes*), need not have any similarity in terms of behavior.

A new interface relationship

The fact that both classes implemented the interface named **X** created a new relationship among the classes, which is not based on class inheritance.

Back to Question 5 (p. 2567)

7.13.6.7 Answer 4

C. Base A-intfcMethod

7.13.6.7.1 Explanation 4

Illustrates the use of an interface as a type

The program defines a class named **Base** , and a class named **A** , which extends **Base** , and implements an interface named **X** , as shown below.

```

class Base{
    public void inherMethod(){
        System.out.print("Base ");
    }//end inherMethod()
}//end class Base

class A extends Base implements X{
    public void inherMethod(){
        System.out.print(
            " A-inherMethod ");
    }//end inherMethod()

    public void intfcMethod(){
        System.out.print("A-intfcMethod ");
    }//end intfcMethod()
}//end class A

interface X{
    public void intfcMethod();
}//end X

```

Implementing interfaces

A class may implement none, one, or more interfaces.

The cardinal rule on interfaces

If a class implements one or more interfaces, that class must either be declared abstract, or it must provide concrete definitions of all methods declared in and inherited into all of the interfaces that it implements. If the class is declared abstract, its subclasses must provide concrete definitions of the interface methods.

A concrete definition of an interface method

The interface named **X** in this program declares a method named **intfcMethod** . The class named **A** provides a concrete definition of that method.

(The minimum requirement for a concrete definition is a method that matches the method signature and has an empty body.)

Storing object's reference as an interface type

The interesting part of the program is shown in the following code fragment.

```

void doIt(){
    Base myVar1 = new Base();
    myVar1.inherMethod();
    X myVar2 = new A();
}

```

```

    myVar2.intfcMethod();

    System.out.println("");
} //end doIt()

```

The above fragment instantiates a new object of the class named **A** , and saves a reference to that object in a reference variable of the declared type **X** .

How many ways can you save an object's reference?

Recall that a reference to an object can be held by a reference variable whose type matches any of the following:

- The class from which the object was instantiated.
- Any superclass of the class from which the object was instantiated.
- Any interface implemented by the class from which the object was instantiated.
- Any interface implemented by any superclass of the class from which the object was instantiated.
- Any superinterface of the interfaces mentioned above.

Save object's reference as implemented interface type

In this program, the type of the reference variable matches the interface named **X** , which is implemented by the class named **A** .

What does this allow you to do?

When a reference to an object is held by a reference variable whose type matches an interface implemented by the class from which the object was instantiated, that reference can be used to call any method declared in or inherited into that interface.

(That reference cannot be used to call methods not declared in or not inherited into that interface.)

In this simple case ...

The method named **intfcMethod** is declared in the interface named **X** and implemented in the class named **A** .

Therefore, the method named **intfcMethod** can be called on an object instantiated from the class named **A** when the reference to the object is held in a reference variable of the interface type.

*(The method could also be called if the reference is being held in a reference variable of declared type **A** .)*

The call to the method named **intfcMethod** causes the text **A-intfcMethod** to appear on the screen.

Back to Question 4 (p. 2566)

7.13.6.8 Answer 3

C. Base A-intfcMethod

7.13.6.8.1 Explanation 3

What is runtime polymorphic behavior?

One way to describe runtime polymorphic behavior is:

The runtime system selects among two or more methods having the same signature, not on the basis of the type of the reference variable in which an object's reference is stored, but rather on the basis of the class from which the object was originally instantiated.

Illustrates simple class and interface inheritance

The program defines a class named **Base** , and a class named **A** , which extends **Base** , and implements the interface named **X** , as shown in the following fragment.

```

class Base{
public void inherMethod(){
    System.out.print("Base ");
} //end inherMethod()
} //end class Base

class A extends Base implements X{
public void inherMethod(){
    System.out.print(
        " A-inherMethod ");
} //end inherMethod()

public void intfMethod(){
    System.out.print("A-intfMethod ");
} //end intfMethod()
} //end class A

interface X{
public void intfMethod();
} //end X

```

Define an interface method

The interface named **X** declares a method named **intfMethod**. A concrete definition of that method is defined in the class named **A**.

A new object of type Base

The code in the following fragment instantiates a new object of the class **Base** and calls its **inherMethod**. This causes the word **Base** to appear on the output screen. There is nothing special about this. This is a simple example of the use of an object's reference to call one of its instance methods.

```

void doIt(){
Base myVar1 = new Base();
myVar1.inherMethod();
}

```

A new object of type A

The following fragment instantiates a new object of the class **A** and calls its **intfMethod**. This causes the text **A-intfMethod** to appear on the output screen. There is also nothing special about this. This is also a simple example of the use of an object's reference to call one of its instance methods.

```

A myVar2 = new A();
myVar2.intfMethod();

System.out.println("");
} //end doIt()

```

Not polymorphic behavior

The fact that the class named **A** implements the interface named **X** does not indicate polymorphic behavior in this case. Rather, this program is an example of simple class and interface inheritance.

Interface type is not used

The program makes no use of the interface as a type, and exhibits no polymorphic behavior (*no decision among methods having the same signature is required*).

The class named **A** inherits an abstract method named **intfcMethod** from the interface and must define it. (*Otherwise, it would be necessary to declare the class named **A** abstract.*)

The interface is not a particularly important player in this program.

Back to Question 3 (p. 2565)

7.13.6.9 Answer 2

A. Compiler Error

7.13.6.9.1 Explanation 2

Simple hierarchical polymorphic behavior

This program is designed to test your knowledge of simple hierarchical polymorphic behavior.

Implement the interface named **X**

This program defines a class named **A** that extends a class named **Base**, and implements an interface named **X**, as shown in the following code fragment.

```
class A extends Base implements X{
    public void inherMethod(){
        System.out.print(
            " A-inherMethod ");
    }//end inherMethod()

    public void intfcMethod(){
        System.out.print("A-intfcMethod ");
    }//end intfcMethod()
}//end class A

interface X{
    public void intfcMethod();
}//end X
```

Override and define some methods

The class named **A** overrides the method named **inherMethod**, which it inherits from the class named **Base**. It also provides a concrete definition of the method named **intfcMethod**, which is declared in the interface named **X**.

Store object's reference as superclass type

The program instantiates an object of the class named **A** and assigns that object's reference to a reference variable of type **Base**, as shown in the following code fragment.

```
Base myVar2 = new A();
```

Oops! Cannot call this method

So far, so good. However, the next fragment shows where the program turns sour. It attempts to call the method named **intfcMethod** on the object's reference, which was stored as type **Base**.

```
myVar2.intfcMethod();
```

Polymorphic behavior doesn't apply here

Because the class named **Base** does not define the method named **intfcMethod**, hierarchical polymorphic behavior does not apply. Therefore a reference to the object being stored as type **Base** cannot be used to directly call the method named **intfcMethod**, and the program produces a compiler error.

What is the solution?

Hierarchical polymorphic behavior is possible only when the class defining the type of the reference (or *some superclass of that class*) contains a definition for the method that is called on the reference.

There are a couple of ways that downcasting could be used to solve the problem in this case.

Back to Question 2 (p. 2563)

7.13.6.10 Answer 1

A. Compiler Error

7.13.6.10.1 Explanation 1

I put this question in here just to see if you are still awake.

Can store reference as interface type

A reference to an object instantiated from a class can be assigned to any reference variable whose declared type is the name of an interface implemented by the class from which the object was instantiated, or implemented by any superclass of that class.

Define two classes and an interface

This program defines a class named **A** that extends a class named **Base**. The class named **Base** extends **Object** by default.

The program also defines an interface named **X**.

Instantiate an object

The following statement instantiates an object of the class named **A**, and attempts to assign that object's reference to a reference variable whose type is the interface type named **X**.

```
X myVar2 = new A();
```

Interface **X** is defined but not implemented

None of the classes named **A**, **Base**, and **Object** implement the interface named **X**. Therefore, it is not allowable to assign a reference to an object of the class named **A** to a reference variable whose declared type is **X**. Therefore, the program produces the following compiler error under JDK 1.3:

```
Ap131.java:20: incompatible types
found   : A
required: X
    X myVar2 = new A();
```

7.14.2 Preface

This module is part of a self-assessment test designed to help you determine how much you know about object-oriented programming using Java.

The test consists of a series of questions with answers and explanations of the answers.

The questions and the answers are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back.

I recommend that you open another copy of this document in a separate browser window and use the links to under Listings (p. 2602) to easily find and view the listings while you are reading about them.

7.14.3 Questions

7.14.3.1 Question 1 .

What output is produced by the program shown in Listing 1 (p. 2594) ?

- A. Compiler Error
- B. Runtime Error
- C. Joe Joe false
- D. Joe Joe true
- E. None of the above.

²²This content is available online at <<http://cnx.org/content/m45310/1.6/>>.

7.14.6 Answers

7.14.6.1 Answer 10

Both of the following occur.

- C. AB CD EF
- B. Runtime Error

7.14.6.1.1 Explanation 10

Another index out of bounds

This is another example of a program that throws an index out of bounds exception. In this case, since the container is an array object, the name of the exception is **ArrayIndexOutOfBoundsException** .

Populate a three-element array object

The code in the following fragment creates and populates a three-element array object containing reference to three **String** objects.

```
void doIt(){
String[] ref = {"AB ", "CD ", "EF "};
```

Access an out-of-bounds element

The next fragment attempts to access elements at indices 0 through 3 inclusive.

```

        for(int i = 0; i <= 3; i++){
            System.out.print(ref[i]);
        }//end forloop

```

Since index value 3 is outside the bounds of the array, the program throws the following exception and aborts:

```

AB CD EF
java.lang.ArrayIndexOutOfBoundsException
at Worker.doIt(Ap150.java:22)
at Ap150.main(Ap150.java:14)

```

Note however that the program displays the contents of the three **String** objects referred to by the contents of the first three elements in the array before the problem occurs.

That's the way it often is with runtime errors. Often, a program will partially complete its task before getting into trouble and aborting with a runtime error.

Back to Question 10 (p. 2602)

7.14.6.2 Answer 9

B. Runtime Error

7.14.6.2.1 Explanation 9

A setup

If you feel like you've been had, chances are you have been had. The purpose for Question 8 (p. 2600) was to set you up for this question.

Division by zero for integer types

This program deals with the process of dividing by zero for **int** types. The code in the following fragment divides the **int** value 1 by the **int** value 0.

```

void doIt(){
    System.out.println(1/0);
} //end doIt()

```

Not the same as *double* divide by zero

However, unlike with type **double**, this process doesn't return a very large value and continue running. Rather, for type **int**, attempting to divide by zero will result in a runtime error of type **ArithmeticException** that looks something like the following under JDK 1.3:

```

java.lang.ArithmeticException: / by zero
at Worker.doIt(Ap149.java:20)
at Ap149.main(Ap149.java:14)

```

An exercise for the student

I won't attempt to explain the difference in behavior for essentially the same problem between type **int** and type **double**. As the old saying goes, I'll leave that as an exercise for the student.

Back to Question 9 (p. 2601)

7.14.6.3 Answer 8

C. Infinity

7.14.6.3.1 Explanation 8**A double *divide by zero* operation**

This program deals with the process of dividing by zero for floating values of type **double** .
The following code fragment attempts to divide the double value 1.0 by the double value 0.

```
void doIt(){
    System.out.println(1.0/0);
} //end doIt()
```

The program runs successfully, producing the output **Infinity** .

What is Infinity?

Suffice it to say that Infinity is a very large number.

(Any value divided by zero is a very large number.)

At this point, I'm not going to explain it further. If you are interested in learning what you can do with **Infinity** , see the language specifications.

Back to Question 8 (p. 2600)

7.14.6.4 Answer 7

B. Runtime Error

7.14.6.4.1 Explanation 7

This program illustrates an **IndexOutOfBoundsException** exception.

Instantiate and populate an ArrayList object

By now, you will be familiar with the kind of container object that you get when you instantiate the **ArrayList** class.

The code in the following fragment instantiates such a container, having an initial capacity of one element. Then it adds two elements to the container. Each element is a reference to an object of the class **String**

```
void doIt(){
    ArrayList ref = null;
    ref = new ArrayList(1);
    ref.add("ABC ");
    ref.add("DEF ");
}
```

Increase capacity automatically

Because two elements were successfully added to a container having an initial capacity of only one element, the container was forced to increase its capacity automatically.

Following execution of the code in the above fragment, **String** object references were stored at index locations 0 and 1 in the **ArrayList** object.

Get reference at index location 2

The next fragment attempts to use the **get** method to fetch an element from the container at index value 2.

Index values in an **ArrayList** object begin with zero. Therefore, since only two elements were added to the container in the earlier fragment, there is no element at index value 2.

```
System.out.println(
    (String)ref.get(0) +
    (String)ref.get(1) +
    (String)ref.get(2));
```

An **IndexOutOfBoundsException** exception

As a result, the program throws an **IndexOutOfBoundsException** exception. The error produced under JDK 1.3 looks something like the following:

```
Exception in thread "main" java.lang.IndexOutOfBoundsException:
Index: 2, Size: 2
at java.util.ArrayList.RangeCheck
(Unknown Source)
at java.util.ArrayList.get
(Unknown Source)
at Worker.doIt(Ap147.java:27)
at Ap147.main(Ap147.java:16)
```

Attempting to access an element with a negative index value would produce the same result.

An **ArrayIndexOutOfBoundsException** exception

A similar result occurs if you attempt to access an element in an ordinary array object outside the bounds of the index values determined by the size of the array. However, in that case, the name of the exception is **ArrayIndexOutOfBoundsException**.

Back to Question 7 (p. 2599)

7.14.6.5 Answer 6

B. Runtime Error

7.14.6.5.1 Explanation 6

The infamous *NullPointerException*

Interestingly, one of the first things that you read when you start reading Java books, is that there are *no pointers in Java*. It is likely that shortly thereafter when you begin writing, compiling, and executing simple Java programs, one of your programs will abort with an error message looking something like that shown below :

```
Exception in thread "main" java.lang.NullPointerException
at
Worker.doIt(Ap146.java:23)
at
Ap146.main(Ap146.java:16)
```

What is a NullPointerException?

Stated simply, a **NullPointerException** occurs when you attempt to perform some operation on an object using a reference that doesn't refer to an object.

That is the case in this program

The following code fragment declares a local reference variable and initializes its value to **null** .

```
void doIt(){
    ArrayList ref = null;
```

(A reference variable in Java must either refer to a valid object, or specifically refer to no object (null). Unlike a pointer in C and C++, a Java reference variable cannot refer to something arbitrary.)

In this case, null means that the reference variable doesn't refer to a valid object.

No ArrayList object

Note that the code in the above fragment does not instantiate an object of the class **ArrayList** and assign that object's reference to the reference variable.

*(The reference variable doesn't contain a reference to an object instantiated from the class named **ArrayList** , or an object instantiated from any class for that matter.)*

Call a method on the reference

However, the code in the next fragment attempts to add a **String** object's reference to a nonexistent **ArrayList** object by calling the **add** method on the reference containing null.

```
ref.add("ABC ");
```

This results in the **NullPointerException** shown earlier (p. 2606) .

What can you do with a null reference?

The only operation that you can perform on a reference variable containing null is to assign an object's reference to the variable. Any other attempted operation will result in a **NullPointerException** .

Back to Question 6 (p. 2598)

7.14.6.6 Answer 5

C. ABC DEF GHI

7.14.6.6.1 Explanation 5

The purpose of this program is to

- Continue to illustrate the use of java packages, and
- Illustrate the use of the Java import directive.

Program contains an import directive

This program is the same as the program in Question 4 (p. 2596) with a major exception. Specifically, the program contains the *import directive* shown in the following fragment.

```
import java.util.ArrayList;
```

A shortcut

The designers of Java recognized that having to type a fully-qualified name for every reference to a class in a Java program can become burdensome. Therefore, they provided us with a shortcut that can be used, so long as we don't need to refer to two or more class files having the same name.

Import directives

The shortcut is called an import directive.

As can be seen above, the import directive consists of the word *import* followed by the fully-qualified name of a class file that will be used in the program.

A program may have more than one import directive, with each import directive specifying the location of a different class file.

The import directive(s) must appear before any class or interface definitions in the source code.

The alternative wild-card syntax

An alternative form of the import directive replaces the name of the class with an asterisk.

The asterisk behaves as a wild-card character. It tells the compiler to use any class file that it finds in that package that matches a class reference in the source code.

The wild-card form should be used with care, because it can sometimes cause the compiler to use a class file that is different from the one that you intended to use (*if it finds the wrong one first*).

Class file name collisions

If your source code refers to two different class files having the same name, you must forego the use of the import directive and provide fully-qualified names for those class files.

Back to Question 5 (p. 2597)

7.14.6.7 Answer 4

A. Compiler Error

7.14.6.7.1 Explanation 4

The purpose of this program is to continue to illustrate the use of java packages.

No fully-qualified class names

This program is the same as the program in Question 3 (p. 2595) with a major exception. Neither of the references to the **ArrayList** class use fully-qualified names in this program. Rather, the references are as shown in the following fragment.

```
ArrayList ref =
    new ArrayList(1);
```

Compiler errors

As a result, the JDK 1.3 compiler produces two error messages similar to the following:

```
Ap144.java:20: cannot resolve symbol
symbol   : class ArrayList
location: class Worker
ArrayList ref =
```

Doesn't know how to find the class file

This error message indicates that the compiler didn't know where to look on the disk to find the file named **ArrayList.class**

Back to Question 4 (p. 2596)

7.14.6.8 Answer 3

C. ABC DEF GHI

7.14.6.8.1 Explanation 3**Illustrate the use of java packages**

Since it was necessary to make use of a class to illustrate packages, this program also previews the use of the `ArrayList` class. We will be very interested in this class later when we study Java data containers.

What is an ArrayList object?

Some of this terminology may not make much sense to you at this point, but I'll go ahead and tell you anyway, just as a preview.

According to Sun, the `ArrayList` class provides a

"Resizable-array implementation of the `List` interface. Implements all optional list operations, and permits all elements, including null. In addition to implementing the `List` interface, this class provides methods to manipulate the size of the array that is used internally to store the list. (This class is roughly equivalent to `Vector` , except that it is unsynchronized.)"

Stated more simply ...

Stated more simply, an object of the `ArrayList` class can be used as a replacement for an array object. An `ArrayList` object knows how to increase its capacity on demand, whereas the capacity of a simple array object cannot change once it is instantiated.

An ArrayList object

The following statement instantiates a new object of the `ArrayList` class, with an initial capacity for one element. The initial capacity is determined by the `int` value passed to the constructor when the object is instantiated.

```
java.util.ArrayList ref =
    new java.util.ArrayList(1);
```

Back to the primary purpose ...

Getting back to the primary purpose of this program, what is the meaning of the term `java.util` that appears ahead of the name of the class, `ArrayList` ?

Avoiding name conflicts

One of the age-old problems in computer programming has to do with the potential for name conflicts. The advent of OOP and reusable code didn't cause that problem to go away. If anything, it made the problem worse.

For example, you and I may work as programmers for separate companies named X and Y. A company named Z may purchase our two companies and attempt to merge the software that we have written separately. Given that there are only a finite number of meaningful class names, there is a good possibility that you and I may have defined different classes with the same names. Furthermore, it may prove useful to use both of the class definitions in a new program.

Put class files in different directories

Sun's solution to the problem is to cause compiled class files to reside in different directories. Simplifying things somewhat, if your compiled file for a class named `Joe` is placed in a directory named `X` , and my compiled file for a different class named `Joe` is placed in a directory named `Y` , then source code in the same Java program can refer to those two class files as `X.Joe` and `Y.Joe` . This scheme makes it possible for the Java compiler and the Java virtual machine to distinguish between the two files having the name `Joe.class` .

The java and util directories

Again, simplifying things slightly, the code in the above fragment refers to a file named `ArrayList.class` , which is stored in a directory named `util` , which is a subdirectory of a directory named `java` .

The directory named `java` is the root of a directory tree containing a very large number of standard Java class files.

(As an aside, there is another directory named `javax`, which forms the root of another directory tree containing class files considered to be extensions to the standard class library.)

Many directories (packages)

Stated simply, a Java package is nothing more or less than a directory containing class files.

The standard and extended Java class libraries are scattered among a fairly large number of directories or packages *(a quick count of the packages in the JDK 1.3 documentation indicates that there are approximately 65 standard and extended packages)* .

A fully-qualified class name

With one exception, whenever you refer to a class in a Java program, you must provide a fully-qualified name for the class, including the path through the directory tree culminating in the name of the class. Thus, the following is the fully-qualified name for the class whose name is `ArrayList` .

`java.util.ArrayList`

(Later we will see another way to accomplish this that requires less typing effort.)

The exception

The one exception to the rule is the use of classes in the `java.lang` package, *(such as `Boolean` , `Class` , and `Double`)* . Your source code can refer to classes in the `java.lang` package without the requirement to provide a fully-qualified class name.

An ArrayList object

Now back to the use of the object previously instantiated from the class named `ArrayList` . This is the kind of object that is often referred to as a container.

(A container in this sense is an object that is used to store references to other objects.)

Many methods available

An object of the `ArrayList` class provides a variety of methods that can be used to store object references and to fetch the references that it contains.

The add method

One of those methods is the method named `add` .

The following code fragment instantiates three objects of the `String` class, and stores them in the `ArrayList` object instantiated earlier.

(Note that since the initial capacity of the `ArrayList` object was adequate to store only a single reference, the following code causes the object to automatically increase its capacity to at least three.)

```
ref.add("ABC ");
ref.add("DEF ");
ref.add("GHI");
```

The get() method

The references stored in an object of the `ArrayList` class can be fetched by calling the `get` method on a reference to the object passing a parameter of type `int` .

The code in the following fragment calls the `get` method to fetch the references stored in index locations 0, 1, and 2. These references are passed to the `println` method, where the contents of the `String` objects referred to by those references are concatenated and displayed on the computer screen.

```
System.out.println(
    (String)ref.get(0) +
    (String)ref.get(1) +
    (String)ref.get(2));
```

The output

This results in the following being displayed:

```
ABC DEF GHI
```

Summary

The above discussion gave you a preview into the use of containers in general, and the `ArrayList` container in particular.

However, the primary purpose of this program was to help you to understand the use of packages in Java.

The `ArrayList` class was simply used as an example of a class file that is stored in a standard Java package.

Back to Question 3 (p. 2595)

7.14.6.9 Answer 2

D. Joe Joe true

7.14.6.9.1 Explanation 2**Two String objects with identical contents**

As in Question 1 (p. 2593), the program instantiates two `String` objects containing identical character strings, as shown in the following code fragment.

```
char[] anArray = {'J','o','e'};
String Str1 = new String(anArray);
String Str2 = new String(anArray);
```

Compare objects for equality

Also, as in Question 1 (p. 2593), this program compares the two objects for equality and displays the result as shown by the call to the `equals` method in the following fragment.

```
System.out.println(
    Str1 + " " + Str2 + " " +
    Str1.equals(Str2));
```

Compare using overridden equals method

The `==` operator is not used to compare the two objects in this program. Instead, the objects are compared using an overridden version of the `equals` method. In this case, the `equals` method returns true, indicating that the objects are of the same type and contain the same data values.

The equals method

The `equals` method is defined in the `Object` class, and can be overridden in subclasses of `Object`. It is the responsibility of the author of the subclass to override the method so as to implement that author's concept of "equal" insofar as objects of the class are concerned.

The overridden equals method

The reason that the `equals` method returned true in this case was that the author of the `String` class provided an overridden version of the `equals` method.

The default equals method

If the author of the class does not override the `equals` method, and the default version of the `equals` method inherited from `Object` is called on an object of the class, then according to Sun:

"for any reference values x and y, this method returns true if and only if x and y refer to the same object (x==y has the value true)"

In other words, the default version of the **equals** method inherited from the class **Object** provides the same behavior as the `==` operator when applied to object references.

Back to Question 2 (p. 2594)

7.14.6.10 Answer 1

C. Joe Joe false

7.14.6.10.1 Explanation 1

The identity operator

This program illustrates the behavior of the `==` operator (*sometimes referred to as the identity operator*) when used to compare references to objects.

Two String objects with identical contents

As shown in the following fragment, this program instantiates two objects of the **String** class containing identical character strings.

```
class Worker{
void doIt(){
    char[] anArray = {'J','o','e'};
    String Str1 = new String(anArray);
    String Str2 = new String(anArray);
}
```

The fact that the two **String** objects contain identical character strings is confirmed by:

- Both objects are instantiated using the same array object of type **char** as input.
- When the **toString** representations of the two objects are displayed later, the display of each object produces Joe on the computer screen.

Compare object references using identity (`==`)

The references to the two **String** objects are compared using the `==` operator, and the result of that comparison is displayed. This comparison will produce either true or false. The code to accomplish this comparison is shown in the following fragment.

```
System.out.println(
    Str1 + " " + Str2 + " " +
    (Str1 == Str2));
```

The statement in the above fragment produces the following display:

Joe Joe false

How can this be false?

We know that the two objects are of the same type (**String**) and that they contain the same character strings. Why does the `==` operator return false?

Doesn't compare the objects

The answer lies in the fact that the above statement doesn't really compare the two objects at all. Rather, it compares the values stored in the reference variables referring to the two objects. That is not the same as comparing the objects.

References are not equal

Even though the objects are of the same type and contain the same character string, they are two different objects, located in different parts of memory. Therefore, the contents of the two reference variables containing references to the two objects are not equal.

The correct answer is *false*

The == operator returns ***false*** as it should. The only way that the == operator could return ***true*** is if both reference variables refer to the same object, (*which is not the case*) .

The bottom line is ...

The == operator cannot be used to compare two objects for equality. However, it can be used to determine if two reference variables refer to the same object.

7.15.2 Preface

This module is part of a self-assessment test designed to help you determine how much you know about object-oriented programming using Java.

The test consists of a series of questions with answers and explanations of the answers.

The questions and the answers are connected by hyperlinks to make it easy for you to navigate from the question to the answer and back.

I recommend that you open another copy of this document in a separate browser window and use the links to under Listings (p. 2623) to easily find and view the listings while you are reading about them.

7.15.3 Questions

7.15.3.1 Question 1 .

What output is produced by the program shown in Listing 1 (p. 2614) ?

- A. Compiler Error
- B. Runtime Error
- C. OK OK
- D. OK
- E. None of the above.

²³This content is available online at <<http://cnx.org/content/m45302/1.5/>>.

Listing 1 . Listing for Question 1.

```
public class Ap151{
public static void main(
                String args[]){
    new Worker().doIt();
} //end main()
} //end class Ap151

class Worker{
void doIt(){
    Object refA = new MyClassA();
    Object refB =
        (Object)(new MyClassB());
    System.out.print(refA);
    System.out.print(refB);
    System.out.println("");
} //end doIt()
} // end class Worker

class MyClassA{
public String toString(){
    return "OK ";
} //end test()
} //end class MyClassA

class MyClassB{

Answer and Explanation (p. 2625)

7.15.3.10 Question 10

What output is produced by the program shown in Listing 11 (p. 2623) ?

- A. Compiler Error
- B. Runtime Error
- C. Joe Tom
- D. None of the above.

Listing 11 . Listing for Question 10.

```
public class Ap160{
public static void main(
                String args[]){
    new Worker().doIt();
} //end main()
} //end class Ap160

class Worker{
void doIt(){
    char[] ref = {'J','o','e'};
    System.out.print(ref);
    System.out.print(" ");
    ref[0] = 'T';
    ref[1] = 'o';
    ref[2] = 'm';
    System.out.println(ref);
} //end doIt()
} // end class Worker
```

7.15.6 Answers

7.15.6.1 Answer 10

C. Joe Tom

7.15.6.1.1 Explanation 10

This is an upgrade to the program from Question 9 (p. 2621) .

Success at last

The code in the following fragment resolves the compilation problem from Question 8 and the runtime problem from Question 9 (p. 2621) .

```

    void doIt(){
    char[] ref = {'J','o','e'};
    System.out.print(ref);
    System.out.print(" ");
    ref[0] = 'T';
    ref[1] = 'o';
    ref[2] = 'm';
    System.out.println(ref);
    }//end doIt()

```

Simply initializing the local reference variable named **ref** satisfies the compiler, making it possible to compile the program.

Initializing the local reference variable named **ref** with a reference to a valid array object eliminates the `NullPointerException` that was experienced in Question 9 (p. 2621) .

Printing the contents of the array object

The `print` statement passes the reference variable to the `print` method. The `print` method finds that the reference variable refers to a valid object (*instead of containing null as was the case in Question 9* (p. 2621)) and behaves accordingly.

The `print` statement causes the initialized contents of the array object to be displayed. Then those contents are replaced with a new set of characters. The `println` statement causes the new characters to be displayed.

Back to Question 10 (p. 2622)

7.15.6.2 Answer 9

B. Runtime Error

7.15.6.2.1 Explanation 9

Purposely initializing a local variable

This is an update to the program from Question 8 (p. 2620) . The code in the following fragment solves the compilation problem identified in Question 8 (p. 2620) .

```
void doIt(){
    char[] ref = null;
```

In particular, initializing the value of the reference variable named `ref` satisfies the compiler and makes it possible to compile the program.

A `NullPointerException`

However, there is still a problem, and that problem causes a runtime error.

The following statement attempts to use the reference variable named `ref` to print something on the screen. This results, among other things, in an attempt to call the `toString` method on the reference. However, the reference doesn't refer to an object. Rather, it contains the value `null` .

```
System.out.print(ref);
```

The result is a runtime error with the following infamous `NullPointerException` message appearing on the screen:

```
java.lang.NullPointerException
at java.io.Writer.write(Writer.java:107)
at java.io.PrintStream.write(PrintStream.java:245)
at java.io.PrintStream.print(PrintStream.java:396)
at Worker.doIt(Ap159.java:22)
at Ap159.main(Ap159.java:15)
```

Back to Question 9 (p. 2621)

7.15.6.3 Answer 8

A. Compiler Error

7.15.6.3.1 Explanation 8

Garbage in, garbage out

Earlier programming languages, notably C and C++ allowed you to inadvertently write programs that process the garbage left in memory by previous programs running there. This happens when the C or C++ programmer fails to properly initialize variables, allowing them to contain left-over garbage from memory.

Member variables are automatically initialized to default values

That is not possible in Java. All member variables in a Java object are automatically initialized to a default value if you don't write the code to initialize them to some other value.

Local variables are not automatically initialized

Local variables are not automatically initialized. However, your program will not compile if you write code that attempts to fetch and use a value in a local variable that hasn't been initialized or had a value assigned to it.

Print an uninitialized local variable

The statement in the following code fragment attempts to fetch and print a value using the uninitialized local variable named `ref`.

```
void doIt(){
char[] ref;
System.out.print(ref);
```

As a result, the program refuses to compile, displaying the following error message under JDK 1.3.

```
Ap158.java:23: variable ref might not have been initialized
System.out.print(ref);
```

Back to Question 8 (p. 2620)

7.15.6.4 Answer 7

See explanation below.

7.15.6.4.1 Explanation 7

The javadoc.exe program

When you download the JDK from Oracle, you receive a program named `javadoc.exe` in addition to several other programs.

The purpose of the `javadoc` program is to help you document the Java programs that you write. You create the documentation by running the `javadoc` program and specifying your source file or files as a command-line parameter. For example, you can generate documentation for this program by entering the following at the command line.

```
javadoc Ap157.java
```

Produces HTML files as output

This will produce a large number of related HTML files containing documentation for the class named `Ap157`. The primary HTML file is named `Ap157.html`. A file named `index.html` is also created.

This file can be opened in a browser to provide a viewer for all of the information contained in the many related HTML files.

(As a labor saving device, you can also specify a group of input files to the javadoc program, using wildcard characters as appropriate, to cause the program to produce documentation files for each of the input files in a single run.)

Special documentation comments and directives

If you include comments in your source code that begin with

```
/**
```

and end with

```
*/
```

they will be picked up by the javadoc program and become part of the documentation.

In addition to comments, you can also enter a variety of special directives to the javadoc program as shown in the following program.

```
public class Ap157{

    /**
    * Returns the character at the
    * specified index. An index ranges from
    * <code>0</code> to
    * <code>length() - 1</code>.
    *
    * @param index index of desired
    * character.
    * @return the desired character.
    */
    public char charAt(int index) {
        //Note, this method is not intended
        // to be operational. Rather, it
        // is intended solely to illustrate
        // the generation of javadoc
        // documentation for the parameter
        // and the return value.
        return 'a';//return dummy char
    }//end charAt method
}//end class
```

The @param and @return directives

The **@param** and **@return** directives in the source code shown above are used by the **javadoc** program for documenting information about parameters passed to and information returned from the method named **charAt** . The method definition follows the special javadoc comment.

Back to Question 7 (p. 2619)

7.15.6.5 Answer 6

C. OK

7.15.6.5.1 Explanation 6

Public classes in separate files

This program meets the requirement identified in Question 5 (p. 2618) . In particular, this program defines two public classes. The source code for each public class is stored in a separate file. Thus, the program compiles and executes successfully, producing the text OK on the screen.

Back to Question 6 (p. 2618)

7.15.6.6 Answer 5

A. Compiler Error

7.15.6.6.1 Explanation 5

Public classes in separate files

Java requires that the source code for every public class be contained in a separate file. In this case, the source code for two public classes was contained in a single file. The following compiler error was produced by JDK 1.3:

```
Ap155.java:18: class Ap155a is public, should be declared in a file
named Ap155a.java
public class Ap155a{
```

Back to Question 5 (p. 2618)

7.15.6.7 Answer 4

This program produces both of the following:

- C. 5 10 15
- B. Runtime Error

7.15.6.7.1 Explanation 4

The NoSuchElementException

This program defines, creates, and uses a very simple container object for the purpose of illustrating the **NoSuchElementException** .

The code in the following fragment shows the beginning of a class named **MyContainer** from which the container object is instantiated.

```
class MyContainer{
private int[] array = new int[3];

public void put(int idx, int data){
    if(idx > (array.length-1)){
        throw new
            NoSuchElementException();
    }else{
        array[idx] = data;
    }//end else
} //end put()
```

A wrapper for an array object

This class is essentially a wrapper for a simple array object of type `int` . An object of the class provides a method named `put` , which can be used to store an `int` value into the array. The `put` method receives two parameters. The first parameter specifies the index of the element where the value of the second parameter is to be stored.

Throw `NoSuchElementException` on index out of bounds

The `put` method tests to confirm that the specified index is within the positive bounds of the array. If not, it uses the `throw` keyword to throw an exception of the type `NoSuchElementException` . Otherwise, it stores the incoming data value in the specified index position in the array.

(Note that a negative index will cause an `ArrayIndexOutOfBoundsException` instead of a `NoSuchElementException` to be thrown.)

The `get` method

An object of the `MyContainer` class also provides a `get` method that can be used to retrieve the value stored in a specified index.

```
public int get(int idx){
    if(idx > (array.length-1)){
        throw new
            NoSuchElementException();
    }else{
        return array[idx];
    }//end else
} //end put()
```

The `get` method also tests to confirm that the specified index is within the positive bounds of the array. If not, it throws an exception of the type `NoSuchElementException` . Otherwise, it returns the value stored in the specified index of the array.

(As noted earlier, a negative index will cause an `ArrayIndexOutOfBoundsException` instead of a `NoSuchElementException` to be thrown.)

The `NoSuchElementException`

Thus, this container class illustrates the general intended purpose of the `NoSuchElementException` .

Instantiate and populate a container

The remainder of the program simply exercises the container. The code in the following fragment instantiates a new container, and uses the `put` method to populate each of its three available elements with the values 5, 10, and 15.

```
void doIt(){
    MyContainer ref =
        new MyContainer();
    ref.put(0,5);
    ref.put(1,10);
    ref.put(2,15);
}
```

Get and display the data in the container

Then the code in the next fragment uses the `get` method to get and display the values in each of the three elements, causing the following text to appear on the screen:

```
5 10 15
```

```

    System.out.print(ref.get(0)+" ");
    System.out.print(ref.get(1)+" ");
    System.out.print(ref.get(2)+" ");

```

One step too far

Finally, the code in the next fragment goes one step too far and attempts to get a value from index 3, which is outside the bounds of the container.

```

    System.out.print(ref.get(3)+" ");

```

This causes the `get` method of the container object to throw a `NoSuchElementException`. The program was not designed to handle this exception, so this causes the program to abort with the following text showing on the screen:

```

    5 10 15 java.util.NoSuchElementException
    at MyContainer.get(Ap154.java:49)
    at Worker.doIt(Ap154.java:30)
    at Ap154.main(Ap154.java:15)

```

(Note that the values of 5, 10, and 15 were displayed on the screen before the program aborted and displayed the error message.)

Back to Question 4 (p. 2616)

7.15.6.8 Answer 3

This program can produce either of the following depending on the value produced by a random boolean value generator:

- B. Runtime Error
- C. OK

7.15.6.8.1 Explanation 3

Throwing an exception

This program illustrates the use of the `throw` keyword to throw an exception.

(Note that the `throw` keyword is different from the `throws` keyword.)

Throw an exception if random boolean value is true

A random `boolean` value is obtained. If the value is true, the program throws an `IllegalStateException` and aborts with the following message on the screen:

```

    java.lang.IllegalStateException
    at Worker.doIt(Ap153.java:29)
    at Ap153.main(Ap153.java:20)

```

If the random **boolean** value is false, the program runs to completion, displaying the text OK on the screen.

Instantiate a Random object

The following code fragment instantiates a new object of the **Random** class and stores the object's reference in a reference variable named **ref** .

```
void doIt(){
    Random ref = new Random(
        new Date().getTime());
```

I'm not going to go into a lot of detail about the **Random** class. Suffice it to say that an object of this class provides methods that will return a pseudo random sequence of values upon successive calls. You might think of this object as a random value generator.

Seeding the random generator

The constructor for the class accepts a **long** integer as the seed for the sequence.

*(Two **Random** objects instantiated using the same seed will produce the same sequence of values.)*

In this case, I obtained the time in milliseconds, relative to January 1, 1970, as a **long** integer, and provided that value as the seed. Thus, if you run the program two times in succession, with a time delay of at least one millisecond in between, the random sequences will be different.

Get a random boolean value

The code in the next fragment calls the **nextBoolean** method on the **Random** object to obtain a random boolean value. *(Think of this as tossing a coin with true on one side and false on the other side.)*

```
if(ref.nextBoolean()){
    throw new IllegalStateException();
```

Throw an exception

If the **boolean** value obtained in the above fragment is true, the code instantiates a new object of the **IllegalStateException** class , and uses the **throw** keyword to throw an exception of this type.

Program aborts

The program was not designed to gracefully handle such an exception. Therefore the program aborts, displaying the error message shown earlier.

Don't throw an exception

The code in the next fragment shows that if the **boolean** value tested above is false, the program will display the text OK and run successfully to completion.

```
    }else{
        System.out.println("OK");
    }//end else
} //end doIt()
```

You may need to run the program several times to see both possibilities.

Back to Question 3 (p. 2615)

7.15.6.9 Answer 2

The answer is both of the following:

- D. OK
- B. Runtime Error

7.15.6.9.1 Explanation 2

One cast is allowable ...

It is allowable, but not necessary, to cast the type of an object's reference toward the root of the inheritance hierarchy.

It is also allowable to cast the type of an object's reference along the inheritance hierarchy toward the actual class from which the object was instantiated.

Another cast is not allowable ...

However, (*excluding interface type casts*) , it is not allowable to cast the type of an object's reference in ways that are not related in a subclass-superclass inheritance sense. For example, you cannot cast the type of an object's reference to the type of a sibling of that object.

Two sibling classes

The code in the following fragment defines two simple classes named **MyClassA** and **MyClassB** . By default, each of these classes extends the class named **Object** . Therefore, neither is a superclass of the other. Rather, they are siblings.

```

class MyClassA{
    public String toString(){
        return "OK ";
    }//end test()
}//end class MyClassA

class MyClassB{
    public String toString(){
        return "OK ";
    }//end test()
}//end class MyClassB

```

Instantiate one object from each sibling class

The code in the next fragment instantiates one object from each of the above classes, and stores references to those objects in reference variables of type **Object**.

Then the code causes the overridden **toString** method of one of the objects to be called by passing that object's reference to the **print** method.

```

void doIt(){
    Object ref1 = new MyClassA();
    Object ref2 = new MyClassB();
    System.out.print(ref1);
}

```

The code in the above fragment causes the text OK to appear on the screen.

Try to cast to a sibling class type

At this point, the reference variable named `ref1` holds a reference to an object of type `MyClassA`. The reference is being held as type `Object`.

The statement in the next fragment attempts to cast that reference to type `MyClassB`, which is a sibling of the class named `MyClassA`.

```
MyClassB ref3 = (MyClassB)ref1;
```

A `ClassCastException`

The above statement causes a `ClassCastException` to be thrown, which in turn causes the program to abort. The screen output is shown below:

```
OK java.lang.ClassCastException:MyClassA
at Worker.doIt(Ap152.java:24)
at Ap152.main(Ap152.java:14)
```

(Note that the text `OK` appeared on the screen before the program aborted and displayed diagnostic information on the screen.)

Back to Question 2 (p. 2614)

7.15.6.10 Answer 1

C. OK OK

7.15.6.10.1 Explanation 1

Type conversion

This program illustrates type conversion up the inheritance hierarchy, both with and without a cast.

Store object's reference as type `Object`

The following fragment instantiates a new object of the class named `MyClassA`, and stores that object's reference in a reference variable of type `Object`. This demonstrates that you can store an object's reference in a reference variable whose type is a superclass of the class from which the object was instantiated, with no cast required.

```
class Worker{
void doIt(){
    Object refA = new MyClassA();
```

Cast object's reference to type `Object`

The code in the next fragment instantiates an object of the class named `MyClassB`, and stores the object's reference in a reference variable of type `Object`, after first casting the reference to type `Object`. This, and the previous fragment demonstrate that while it is allowable to cast a reference to the superclass type before storing it in a superclass reference variable, such a cast is not required.

```
Object refB =
    (Object)(new MyClassB());
```

Type conversion and assignment compatibility

This is part of a larger overall topic commonly referred to as type conversion. It also touches the fringes of something that is commonly referred to as assignment-compatibility.

Automatic type conversions

Some kinds of type conversions happen automatically. For example, you can assign a value of type `byte` to a variable of type `int` and the type conversion will take place automatically.

Cast is required for narrowing conversions

However, if you attempt to assign a value of type `int` to a variable of type `byte`, the assignment will not take place automatically. Rather, the compiler requires you to provide a cast to confirm that you accept responsibility for the conversion, which in the case of `int` to `byte` could result in the corruption of data.

Automatic conversions up the inheritance hierarchy

When working with objects, type conversion takes place automatically for conversions toward the root of the inheritance hierarchy. Therefore, conversion from any class type to type `Object` happen automatically. However, conversions in the direction away from the root require a cast.

(Conversion from any class type to any superclass of that class also happens automatically.)

Polymorphic behavior

The code in the next fragment uses polymorphic behavior to display the contents of the two `String` objects.

```
System.out.print(refA);
System.out.print(refB);
```

No cast required

This works without the use of a cast because the `print` method calls the `toString` method on any object's reference that it receives as an incoming parameter. The `toString` method is defined in the `Object` class, and overridden in the `String` class. Polymorphic behavior dictates that in such a situation, the version of the method belonging to the object will be called regardless of the type of the reference variable holding the reference to the object.

When would a cast be required?

Had the program attempted to call a method on the reference that is not defined in the `Object` class, it would have been necessary to cast the reference down the inheritance hierarchy in order to successfully call the method.

Chapter 8

Anatomy of a Game Engine

8.1 Jy0060: Anatomy of a Game Engine¹

8.1.1 Table of Contents

- Welcome (p. 2635)
- Miscellaneous (p. 2636)

8.1.2 Welcome

Click the link to view the material for Anatomy of a Game Engine ² , which I use in some of the courses that I teach at Austin Community College in Austin, TX.

This is a collection of modules designed to teach students about the anatomy of a typical game or simulation engine (*sometimes called a game or simulation framework*) .

The collection is built around the **Slick2D** Game library.

The Slick2D library

I chose to concentrate on the free game library named Slick2D ³ , (*which is written in Java*) for several reasons including the following:

- Java is the language with which I am the most comfortable. Hence, I can probably do a better job of explaining the anatomy of a game engine that uses Slick2D than would be the case for a game engine written in C++, C#, Python, or some other programming language.
- Java has proven in recent years to be a commercially successful game programming language. For example, I cite the commercial game named Minecraft ⁴ , written in Java, for which apparently millions of copies have been sold. Also, knowing Java is very beneficial for those who might want to develop apps for Android.
- Slick2D is free and the source code for Slick2D is readily available.
- The overall structure of a basic Slick2D game engine is very similar to Dark GDK and XNA, and is probably similar to other game engines as well.
- Java is platform independent.

Applicable to other environments as well

Although the modules in this collection concentrate on the Java game library named Slick2D, the concepts involved and the knowledge that you will gain is applicable to other game engines written in different programming languages.

Chapter 10

Programming Oldies But Goodies

10.1 Jy0050: Programming Oldies But Goodies¹

10.1.1 Table of Contents

- Welcome (p. 2639)
- Miscellaneous (p. 2639)

10.1.2 Welcome

Over the years, I have published a large number of tutorials in the areas of computer programming and DSP. As I have the time to do so, I am converting the more significant of those tutorials into cnxml code and re-publishing them at cnx.org. In the meantime, the collection titled Programming Oldies But Goodies², which is a work in process, gathers many of the tutorials in their original HTML format into a common location to make them readily available for Connexions users.

10.1.3 Miscellaneous

This section contains a variety of miscellaneous information.

NOTE: Housekeeping material

- Module name: Jy0050: Programming Oldies But Goodies
- File: Jy0050.htm
- Published: 01/17/13

NOTE: Disclaimers:: Financial : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

In the past, unknown individuals have copied my modules from cnx.org, converted them to Kindle books, and placed them for sale on Amazon.com showing me as the author. I neither receive

¹This content is available online at <http://cnx.org/content/m45681/1.1/>.

²<http://cnx.org/content/col11478>

compensation for those sales nor do I know who does receive compensation. If you purchase such a book, please be aware that it is a copy of a module that is freely available on cnx.org and that it was made and published without my prior knowledge.

 - * Video tutorials (p. 2645)
 - * Other possibilities (p. 2645)
- What comes next after Greenfoot (p. 2646)
- Miscellaneous (p. 2646)

11.1.2 Preface

If you are new to programming and want to learn how to program, or if you have programming experience but are new to *object-oriented programming (OOP)* and want to learn OOP, I can't think of a better way to take that first step than through the use of Greenfoot ² .

¹This content is available online at <<http://cnx.org/content/m45790/1.2/>>.

²<http://www.greenfoot.org/door>

Greenfoot provides a set of interactive visual tools coupled with the Java programming language that makes learning to program both interesting and productive.

(Note that descriptions of the Greenfoot website contained herein are current as of 02/19/13.)

11.1.3 Overview

11.1.3.1 A visual interactive programming environment

The greenfoot overview ³ page describes Greenfoot as an Interactive Visual World that *"...teaches object orientation with Java."*

When programming with Greenfoot, you *"Create 'actors' which live in 'worlds' to build games, simulations, and other graphical programs."*

Greenfoot is both instructive and enjoyable because it is visual and interactive. Visualization and interaction tools are built into the programming environment.

Unlike Scratch ⁴ and Alice ⁵ (two programming environments for beginners that use a drag-and-drop approach to programming) , Greenfoot actors *"are programmed in standard textual Java code, providing a combination of programming experience in a traditional text-based language with visual execution."*

According to Wikipedia ⁶ ,

"Greenfoot is an interactive Java development environment designed primarily for educational purposes at the high school and undergraduate level. It allows easy development of two-dimensional graphical applications, such as simulations and interactive games."

Greenfoot is being developed and maintained at the University of Kent ⁷ and La Trobe University ⁸ , with support from Oracle ⁹ . It is free software, released under the GPL license. Greenfoot is available for Microsoft Windows ¹⁰ , Mac OS X ¹¹ , Linux ¹² , Sun Solaris ¹³ , and any recent JVM ¹⁴ ."

Continuing with Wikipedia ¹⁵ ,

"Greenfoot aims to motivate learners quickly by providing easy access to animated graphics, sound and interaction. The environment is highly interactive and encourages exploration and experimentation. Pedagogically, the design is based on constructivist and apprenticeship approaches."

Secondly, the environment is designed to illustrate and emphasize important abstractions and concepts of object-oriented programming. Concepts such as the class/object relationship, methods, parameters, and object interaction are conveyed through visualizations and guided interactions. The goal is to build and support a mental model that correctly represents modern object-oriented programming systems."

11.1.3.2 Greenfoot is not a toy

Your first impression when you enter the Greenfoot home page ¹⁶ may be that Greenfoot is a toy, but that definitely is not the case.

³<http://www.greenfoot.org/overview>

⁴<http://scratch.mit.edu/>

⁵<http://www.alice.org/>

⁶<http://en.wikipedia.org/wiki/Greenfoot>

⁷http://en.wikipedia.org/wiki/University_of_Kent

⁸http://en.wikipedia.org/wiki/La_Trobe_University

⁹<http://en.wikipedia.org/wiki/Oracle>

¹⁰http://en.wikipedia.org/wiki/Microsoft_Windows

¹¹http://en.wikipedia.org/wiki/Mac_OS_X

¹²<http://en.wikipedia.org/wiki/Linux>

¹³http://en.wikipedia.org/wiki/Sun_Solaris

¹⁴http://en.wikipedia.org/wiki/Java_Virtual_Machine

¹⁵<http://en.wikipedia.org/wiki/Greenfoot>

¹⁶<http://www.greenfoot.org/home>

While it is true that the first impulse of many beginning programmers is to create computer games (as evidenced on the *home page*¹⁷ and the *Greenfoot Gallery*¹⁸), Greenfoot can also be used to create serious interactive simulations. As an example, I will point you to the following simulations:

- Ants¹⁹ by mik
- Wave-Lab²⁰ by delmar
- Birds and Trees²¹ by polle

(Click a link given above to download and run a simulation. When the simulation window appears, click the Run button on the simulation window to start the simulation running.)

You can view more than 7500 scenarios (Greenfoot programs are commonly referred to as scenarios) by clicking the **Scenarios** link at the top of the home page²². Some of the scenarios are impressive. Some are not so impressive. Many, possibly most, were written by beginning programmers.

(Note that you must have Java applets enabled on your computer to run these simulations. Alternatively, if you have Greenfoot installed on your computer, you can click the "Open in Greenfoot" button to cause the program to be downloaded for compilation and execution locally on your computer.)

11.1.3.3 The Greenfoot Gallery

What you see when you click the **Scenarios** link at the top of the home page²³ has been called the *Greenfoot Gallery*²⁴ in times past. This is a place where the authors of Greenfoot scenarios can publish their scenarios if they so choose.

This is a social network or virtual programming community where Greenfoot programmers gather to encourage one another and to critique the work being done by themselves and others. Note however that active participation in the gallery is completely voluntary.

11.1.4 Software

The Greenfoot software and the Java Development Kit (JDK), both of which run on Windows, Mac, and Linux, are available for free download²⁵.

11.1.4.1 Software to download and install

When you visit the download²⁶ page, you will find download links for Windows, Mac OS X, and Ubuntu. Click one of those links to download and install the appropriate version of Greenfoot on your computer.

You will also need to download and install the Java Development Kit (JDK). There is a download button labeled **Download JDK** for that purpose.

11.1.4.2 Stand alone software

As an alternative to the version that can be installed on your computer, there is a self-contained **Stand Alone** version that you can download, unzip, copy to, and run either from a disk folder or from a USB memory stick with no other installation required. This version contains both the Greenfoot software and the Java JDK.

¹⁷<http://www.greenfoot.org/home>

¹⁸<http://www.greenfoot.org/scenarios>

¹⁹<http://www.greenfoot.org/scenarios/1016>

²⁰<http://www.greenfoot.org/scenarios/597>

²¹<http://www.greenfoot.org/scenarios/267>

²²<http://www.greenfoot.org/home>

²³<http://www.greenfoot.org/home>

²⁴<http://www.greenfoot.org/scenarios>

²⁵<http://www.greenfoot.org/download>

²⁶<http://www.greenfoot.org/download>

Once you extract the software from the zip file, you will need about 200 Mbytes to store it in a disk folder. Depending on the formatting, you may need as much as 275 Mbytes of available space to copy the software to a USB memory stick.

The stand alone version is particularly useful in several situations including the following:

- You want to run Greenfoot on a computer for which you don't have installation privileges, such as in a public library or a college computer lab.
- You don't already have the Java JDK installed on your computer and would prefer not to go through the effort to download and install it.
- You want to run Greenfoot, but you don't want to install anything on your computer.

11.1.5 Running Greenfoot

11.1.5.1 The installed version

If you download and install Greenfoot and the Java JDK on your computer, you will have an opportunity to place a Greenfoot icon on your desktop. Just double-click the icon to start the Greenfoot program running. (*Although not necessary, it is probably best to install the JDK before installing Greenfoot.*)

11.1.5.2 The stand alone version

If you elect to use the stand alone version, you will extract the following folders from the zip file:

- BlueJ ²⁷ (*a more advanced Java programming environment*)
- Greenfoot (*the programming environment of interest in this module*)
- jdk (*the Java Development Kit*)
- userhome (*not sure the purpose of this folder*)

You will find a file named **Greenfoot.exe** inside the **Greenfoot** folder. It will have an icon of a small green footprint. Double click this file to start the Greenfoot program running.

Once the program is running, you can select the *Greenfoot Tutorial* item on the **Help** menu to open a webpage containing a variety of educational tutorials. (*I will have more to say about this later.*) The **Help** menu also provides access to several other useful items, such as documentation for both Greenfoot and the Java JDK.

11.1.6 Textbook and tutorials

There is a textbook titled Introduction to Programming with Greenfoot - Object-Oriented Programming in Java with Games and Simulations ²⁸ that you can purchase on Amazon for about \$75.00. (*As usual, you can rent it for less or purchase a used copy for less.*)

There are also many free online tutorials ²⁹ available to help you get started programming with Java and Greenfoot.

Whether you need the textbook, or whether the tutorials will suffice will depend on your background. My advice is to begin with the tutorials alone, and then purchase the textbook if needed.

²⁷<http://www.bluej.org/>

²⁸<http://www.greenfoot.org/book>

²⁹<http://www.greenfoot.org/doc>

11.1.6.1 The textbook

That having been said, I will comment on the textbook. If I had the luxury of designing a computer programming curriculum from scratch, I would choose a model very similar to the Greenfoot textbook.

In particular, unlike the programming curricula in many colleges and universities, I would begin with the big picture (*classes, interfaces, objects, methods, variables, etc.*) and work my way down to the more detailed aspects of programming (*selection, loops, operators, types, etc.*) .

(The programming curricula at many colleges and universities begin at the bottom and work their way up instead of beginning at the top and working their way down. As a result, many students become bogged down in details and either quit or fail and never get a chance to see the big picture of object-oriented programming.)

Because I believe in the top down model on which the textbook is based, I can recommend this textbook as a very good way to get started learning computer programming in general and object-oriented programming in particular. *(I am not affiliated with the author or the publisher and receive no compensation from the sale of this textbook.)*

11.1.6.2 The tutorials

11.1.6.2.1 Written tutorials

As of 02/19/13, the Greenfoot website provides the following written tutorials to help you learn how to use Greenfoot and begin programming:

- Interacting with Greenfoot ³⁰
- Movement and Key Control ³¹
- Detecting and Removing Actors, and Making Methods ³²
- Saving the World, Making and Playing Sound ³³
- Adding a Randomly Moving Enemy ³⁴
- How to Access One Object From Another ³⁵

11.1.6.2.2 Video tutorials

If you prefer video tutorials, the Joy Of Code ³⁶ is a thorough introduction to Greenfoot broken down into a large number of videos. A wide range of other short videos ³⁷ are also available.

11.1.6.2.3 Other possibilities

Once you become an accomplished Greenfoot programmer, you might be interested in some of the following possibilities, which generally require other resources or more advanced knowledge:

- Kinect with Greenfoot ³⁸ .
- PicoBoard with Greenfoot ³⁹ .
- Sense Board with Greenfoot ⁴⁰ .

³⁰<http://www.greenfoot.org/doc/tut-1>

³¹<http://www.greenfoot.org/doc/tut-2>

³²<http://www.greenfoot.org/doc/tut-3>

³⁵<http://www.greenfoot.org/doc/howto-1>

³⁶<http://www.joyofcode.org/>

³⁷<http://www.youtube.com/user/18km?ob=5#g/u>

³⁸<http://www.greenfoot.org/doc/kinect>

³⁹<http://www.greenfoot.org/doc/pico>

⁴⁰<http://www.greenfoot.org/doc/sense>

- Finch with Greenfoot ⁴¹ .
- Loading native libraries with Greenfoot ⁴² .
- Gamepads with Greenfoot ⁴³ .
- CS Unplugged with Greenfoot ⁴⁴ .
- AP Computer Science with Greenfoot ⁴⁵ .
- Learn Maths with Greenfoot ⁴⁶

11.1.7 What comes next after Greenfoot

While this may sound like an exaggeration, programming with Greenfoot is sort of like riding a bicycle with training wheels. After awhile, you no longer need the training wheels and you are ready to move on to true two-wheeler.

While is it possible to push Greenfoot into some pretty complex and sophisticated scenarios, there comes a time when you need to take the training wheels off and ride that two-wheeler.

Numerous possibilities are possible in this regard. One possibility is BlueJ - The interactive Java environment ⁴⁷ from the same folks who brought you Greenfoot. Like Greenfoot, the BlueJ software is available for free downloading. Also like Greenfoot, a textbook can be purchased and some free tutorials are available.

Another possibility is to continue working through the modules in this collection.

A very good possibility is to do both.

11.1.8 Miscellaneous

This section contains a variety of miscellaneous information.

12.1 Java3140 Java OOP Java Documentation¹

Revised: Fri Apr 08 18:13:10 CDT 2016

This page is included in the following Books:

- *ITSE 2321 - Object-Oriented Programming (Java)* ²
- *Object-Oriented Programming (OOP) with Java* ³

12.1.1 Table of Contents

- Preface (p. 2647)
 - Viewing tip (p. 2648)
 - * Figures (p. 2648)
- Discussion (p. 2648)
- Java Platform, Standard Edition 7 API Specification (p. 2649)
- A universal documentation format (p. 2661)
- Typical usage of the API documentation (p. 2661)
- Summary (p. 2661)
- Miscellaneous (p. 2661)

12.1.2 Preface

This module is one of a series of modules designed to teach you about Object-Oriented Programming (OOP) using Java.

I cannot overemphasize the importance of Oracle's Java documentation ⁴ to aspiring Java programmers. The documentation package, which can be downloaded for installation and local access or accessed online, contains a wealth of information.

In my opinion, it is not possible to write Java programs of any substance without frequent reference to the documentation. No one can memorize everything that they need to know to be a successful Java programmer.

¹This content is available online at <<http://cnx.org/content/m45117/1.4/>>.

²<http://cnx.org/contents/dzOvxPFw>

³http://cnx.org/contents/-2RmHFs_

⁴<http://docs.oracle.com/javase/7/docs/>

(Note that each time Oracle releases a new version of the Java Development Kit (JDK), they also release a new version of the documentation. Therefore, as new versions are released, the links provided in this document may become outdated and may not take you to the latest version of the documentation. However, you should be able to find the latest documentation via an online search.)

12.1.2.1 Viewing tip

I recommend that you open another copy of this module in a separate browser window and use the following links to easily find and view the figures while you are reading about them.

12.1.2.1.1 Figures

- Figure 1 (p. 2654) . Screen shot of the API specification at startup.
- Figure 2 (p. 2660) . Screen shot of the API documentation after selecting the JButton class.

12.1.3 Discussion

Small core language, large class library

The *Java Platform Standard Edition* programming environment consists of a small core programming language and a large class library.

(As of the date of this writing, you can view *The Java Language Specification* ⁵ online. This specification will tell you just about everything that most programmers need to know about the core language.)

The size of the class library grows with the release of each new version of the JDK, because each new version provides capabilities that didn't exist in the previous version. New capabilities are added through the addition of new classes and new interfaces to the library.

The true power of Java resides in the class libraries

Once you understand how OOP is implemented in Java and you get beyond **while** loops, **if** statements, and other fundamental programming concepts, virtually all the power of Java resides in:

- Classes, interfaces, and methods in the various class libraries that you use directly.
- Classes, interfaces, and methods in the various class libraries that you extend.
- New classes, interfaces, and methods that you and others define.

You will always use material from Oracle's standard class libraries. You will often use material from other libraries that you create yourself, or that you obtain from sources outside of Oracle (such as Barb Ericson's *multimedia library* ⁶, for example) .

Top-level online documentation

As of the date of this writing, you can view the top-level page of the documentation for *Java Platform Standard Edition* ⁷ at <http://docs.oracle.com/javase/7/docs/> ⁷ .

A complicated page

When you first view that documentation page, it may appear to be very complicated. Of all the material on the page, the most important is probably the *Application Programming Interface (API)* , which is currently available via a link on the right side of the page labeled Java SE API ⁸ .

However, you should not ignore the links to other information available on the top-level page ⁹ . Those links will often contain information that you need, and that information can make you more efficient in using the API documentation.

Search

⁵http://java.sun.com/docs/books/jls/second_edition/html/j.title.doc.html

⁶<http://coweb.cc.gatech.edu/mediaComp-plan/101>

⁷<http://docs.oracle.com/javase/7/docs/>

⁸<http://docs.oracle.com/javase/7/docs/api/index.html>

⁹<http://docs.oracle.com/javase/7/docs/>

If you follow the Search link at the top of the page, you will arrive at a search engine page ¹⁰ that gives you the ability to do a keyword search on the online documentation.

Downloading and installing Java

Of particular interest to most newcomers should be the links titled Installation Instructions ¹¹ and Java SE Downloads ¹².

The Java Tutorials

Also very important is the link to The Java Tutorials ¹³. Once you reach those tutorials, of particular importance is the Path and CLASSPATH ¹⁴ tutorial. (*Many students trip on the path, the classpath, and the difference between the two.*)

12.1.4 Java Platform, Standard Edition 7 API Specification

The *API Specification* ¹⁵ is probably the most frequently used section of the entire documentation package.

A screen shot

Figure 1 (p. 2654) shows a partial screen shot of what you should see when you first load the API Specification into your browser. (*Note that this screen shot was cropped to force it to fit into this publication format.*)

The screenshot shows the Java Platform, Standard Edition 7 API Specification web page. The page has a dark blue header with the title 'Java™ Platform Standard Ed. 7' and navigation links: Overview, Package, Class, Use, Tree, Deprecated, Index, Help. Below the header is a sub-header with 'Prev Next Frames No Frames'. The main content area is titled 'Java™ Platform, Standard Edition 7 API Specification' and contains the text: 'This document is the API specification for the Java™ Platform, Standard Edition. See: Description'. Below this is a table of packages with the following columns: Package and Description.

Package	Description
java.applet	Provides the classes necessary to create an applet and the classes an applet uses to communicate with its applet context.
java.awt	Contains all of the classes for creating user interfaces and for painting graphics and images.
java.awt.color	Provides classes for color spaces.
java.awt.datatransfer	Provides interfaces and classes for transferring data between and within applications.
java.awt.dnd	Drag and Drop is a direct manipulation gesture found in many Graphical User Interface systems that provides a mechanism to transfer information between two entities logically associated with presentation elements in the GUI.

Table 12.1

Screen layout

The purpose of providing this screen shot is to give you an idea of the general layout of the material as it appears on your screen. As you can see, the layout consists of three frames when viewed in your HTML browser.

(A version without frames is also available by selecting the "No Frames" link at the top of the page. The version without frames is particularly useful for using the "page search" capability of your browser to find something on the page.)

The two leftmost frames

The upper-left frame contains a list of *packages*. The lower-left frame contains a list of the *classes* and *interfaces* that are contained in the package that is selected in the top-left frame.

(The default package selection in the upper-left frame is "All Classes".)

You make selections in these two frames *(or in the link bar at the top of the page)* to control the contents of the rightmost frame.

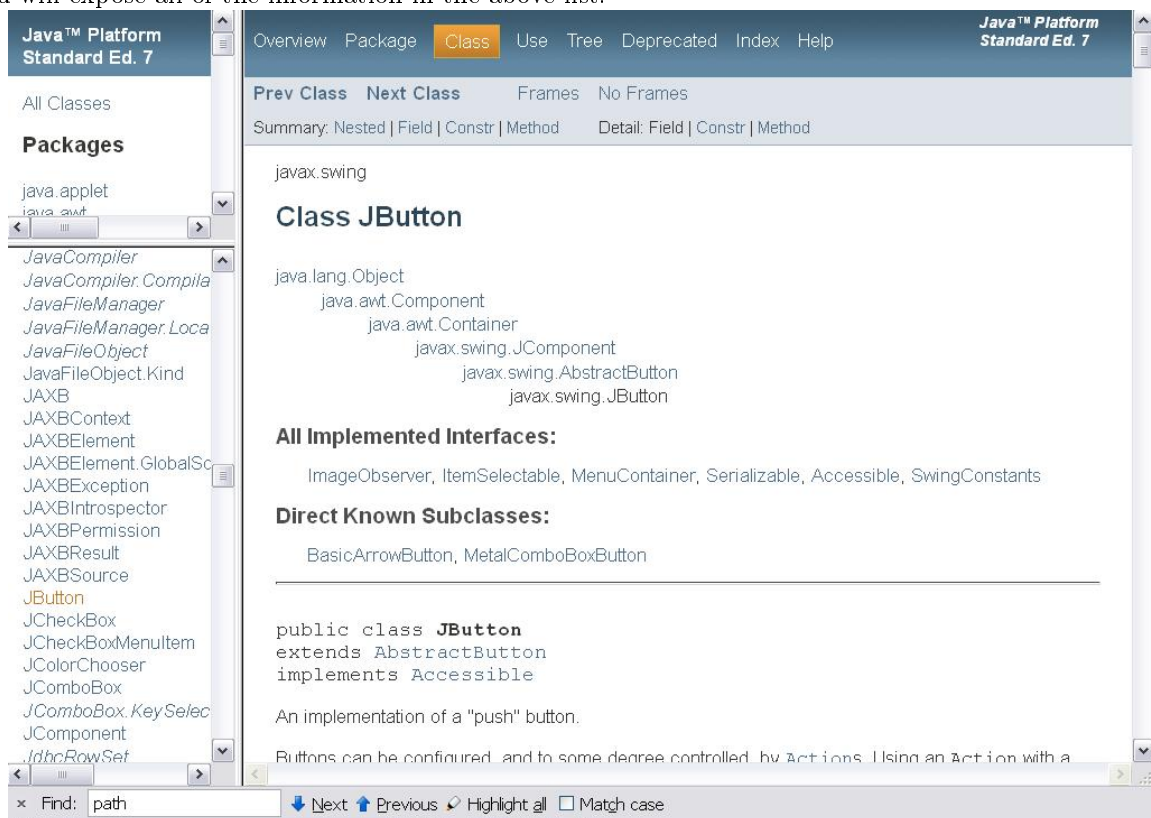

The rightmost frame

When you first access the API documentation *(and when you select **Overview** at the top of the page)*, the rightmost frame contains summary information about all of the packages.

When you select a class in the lower-left frame *(such as the **JButton** class for example)*, the rightmost frame contains hyperlinked information about that class, including:

- A visual class hierarchy diagram
- Interfaces implemented by the class
- Known subclasses of the class
- Text description of the class
- Summary of nested classes
- Summary of fields defined in the class
- Summary of fields inherited into the class
- Summary and detailed information on constructors defined in the class
- Summary and detailed information on methods defined in the class
- List of methods inherited into the class

Figure 2 (p. 2660) shows a screen shot of the browser window after selecting the class named **JButton** in the lower-left frame. If you pull down the thumb in the scroll bar on the right side of the browser window, you will expose all of the information in the above list.

The screenshot shows the Java Platform Standard Ed. 7 documentation interface. The left sidebar lists various packages, with `java.awt` selected. The main content area displays the `Class JButton` page. The page includes a navigation bar with tabs for Overview, Package, Class (selected), Use, Tree, Deprecated, Index, and Help. Below the navigation bar, there are links for Prev Class, Next Class, Frames, and No Frames. The main content area shows the class hierarchy for `javax.swing.JButton`, listing its superclass `java.lang.Object` and its subclasses `java.awt.Component`, `java.awt.Container`, `javax.swing.JComponent`, `javax.swing.AbstractButton`, and `javax.swing.JButton`. It also lists all implemented interfaces: `ImageObserver`, `ItemSelectable`, `MenuContainer`, `Serializable`, `Accessible`, and `SwingConstants`. Direct known subclasses are `BasicArrowButton` and `MetalComboBoxButton`. The class signature is shown as `public class JButton extends AbstractButton implements Accessible`. A brief description states: "An implementation of a 'push' button." and "Buttons can be configured, and to some degree controlled, by Actions. Using an Action with a". The bottom of the page features a search bar with the text "Find: path" and navigation buttons for Next, Previous, Highlight all, and Match case.

The screenshot shows the Java Platform Standard Ed. 7 documentation interface. The left sidebar lists various packages, with `java.awt` selected. The main content area displays the `Class JButton` page. The page includes navigation tabs for `Overview`, `Package`, `Class` (selected), `Use`, `Tree`, `Deprecated`, `Index`, and `Help`. Below the navigation, there are links for `Prev Class`, `Next Class`, `Frames`, and `No Frames`. The main content area shows the class hierarchy for `javax.swing.JButton`, listing its superclass `java.lang.Object` and its subclasses `java.awt.Component`, `java.awt.Container`, `javax.swing.JComponent`, `javax.swing.AbstractButton`, and `javax.swing.JButton`. It also lists **All Implemented Interfaces:** `ImageObserver`, `ItemSelectable`, `MenuContainer`, `Serializable`, `Accessible`, and `SwingConstants`. Under **Direct Known Subclasses:**, it lists `BasicArrowButton` and `MetalComboBoxButton`. The class signature is shown as `public class JButton extends AbstractButton implements Accessible`. A description states: "An implementation of a 'push' button." Below this, a partial sentence reads: "Buttons can be configured, and to some degree controlled, by Actions. Using an Action with a". At the bottom, there is a search bar with the text "Find: path" and navigation buttons for `Next`, `Previous`, `Highlight all`, and `Match case`.

The screenshot shows the Java Platform Standard Ed. 7 documentation interface. The left sidebar lists various packages, with `java.awt` selected. The main content area displays the `Class JButton` page. The page includes a navigation bar with tabs for Overview, Package, Class (selected), Use, Tree, Deprecated, Index, and Help. Below the navigation bar, there are links for 'Prev Class', 'Next Class', 'Frames', and 'No Frames'. The main content area shows the class hierarchy for `javax.swing.JButton`, listing its superclass `java.lang.Object` and its subclasses `java.awt.Component`, `java.awt.Container`, `javax.swing.JComponent`, `javax.swing.AbstractButton`, and `javax.swing.JButton`. It also lists 'All Implemented Interfaces' (ImageObserver, ItemSelectable, MenuContainer, Serializable, Accessible, SwingConstants) and 'Direct Known Subclasses' (BasicArrowButton, MetalComboBoxButton). The class signature is shown as `public class JButton extends AbstractButton implements Accessible`. A description states: 'An implementation of a "push" button.' and 'Buttons can be configured, and to some degree controlled, by Actions. Using an Action with a

Class JButton

java.lang.Object
 java.awt.Component
 java.awt.Container
 javax.swing.JComponent
 javax.swing.AbstractButton
 javax.swing.JButton

All Implemented Interfaces:

ImageObserver, ItemSelectable, MenuContainer, Serializable, Accessible, SwingConstants

Direct Known Subclasses:

BasicArrowButton, MetalComboBoxButton

```
public class JButton
extends AbstractButton
implements Accessible
```

An implementation of a "push" button.

Buttons can be configured, and to some degree controlled, by Actions. Using an Action with a

Find: path Next Previous Highlight all Match case

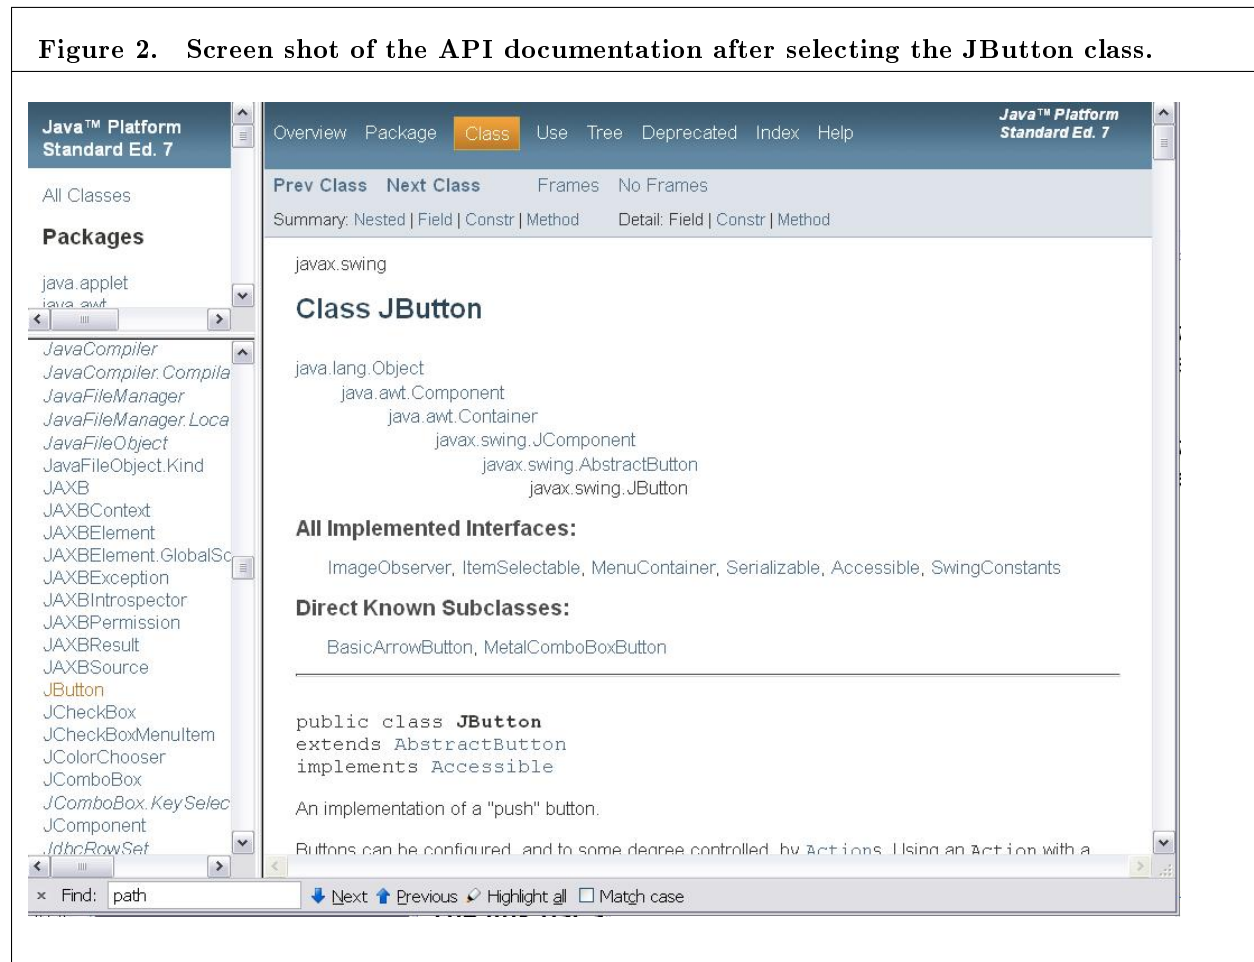

Table 12.2

The link bar at the top of the page

It can sometimes be difficult to find what you are looking for in the documentation package. Referring back to Figure 2 (p. 2660), you can see a link bar at the top of the page in the rightmost frame. This link bar contains the following hyperlinks:

- **Overview** - provides summary information about packages (*shown in Figure 1 (p. 2654)*).
- **Package** - provides a description of the package that contains the class selected in the lower-left frame.
- **Class** - provides a description of the class selected in the lower-left frame.
- **Use** - describes how the class selected in the lower-left frame is used in various packages.
- **Tree** - provides detailed inheritance hierarchy information for a selected package.
- **Deprecated** - provides a list of material that has been deprecated (*may not be supported in future versions*).
- **Index** - provides a hyperlinked alphabetized index of interfaces, classes, constructors, variables, and methods.
- **Help** - Describes how the API document is organized.

The various pages that are displayed by selecting these links can often help you to find what you are looking for. Probably the most useful and frequently consulted item in the above list is the *Index*.

The alphabetical index

The alphabetical index can be extremely useful if you know the full or partial spelling of what you are looking for, beginning with the first character.

For example, assume that you remember *(or you can surmise from what you know about Java properties)* that there is a method whose name begins with `getSystemLookAndFeel`, which returns the name of the `LookAndFeel` class that implements the native look and feel for a particular operating system. You can easily look this up under G in the alphabetical index.

What you will find when you look it up is a brief description of a method named `getSystemLookAndFeelClassName` that matches what you are looking for. The name of the method is also a hyperlink to the detailed description of the same method as it appears in the documentation for the class named `UIManager`.

12.1.5 A universal documentation format

The documentation for the API is created using a program named `javadoc.exe` that is contained in the JDK. Therefore, the API documentation for class libraries obtained from outside sources should have the same format as that described above *(assuming that the documentation was produced using javadoc.exe)*.

However, the program named `javadoc.exe` only controls the format of the documentation. It does not produce the explanatory content. It is the responsibility of the author of the class library to provide that content.

12.1.6 Typical usage of the API documentation

Typical usage of the API documentation consists of the following steps:

- Open the API documentation in your browser.
- Click the class of interest in the lower-left frame.
- Manually search the rightmost frame for summary information about fields, constructors, or methods of interest.
- Click the name of a field, constructor, or method in the summary section to open a detailed description of that field, constructor, or method.

12.1.7 Summary

There are several ways to search for useful information in the Oracle documentation. There is no single approach that will serve all of your needs to find information in the documentation. You simply need to become familiar with the different ways to search for information in the documentation and be prepared to use the approach that does the best job in each situation.

12.1.8 Miscellaneous

This section contains a variety of miscellaneous information.

Housekeeping material

- Module name: Java OOP: Java Documentation
- File: Java3140.htm
- Published: 11/11/12

Disclaimers: **Financial** : Although the Connexions site makes it possible for you to download a PDF file for this module at no charge, and also makes it possible for you to purchase a pre-printed

version of the PDF file, you should be aware that some of the HTML elements in this module may not translate well into PDF.

I also want you to know that, I receive no financial compensation from the Connexions website even if you purchase the PDF version of the module.

In the past, unknown individuals have copied my modules from cnx.org, converted them to Kindle books, and placed them for sale on Amazon.com showing me as the author. I neither receive compensation for those sales nor do I know who does receive compensation. If you purchase such a book, please be aware that it is a copy of a module that is freely available on cnx.org and that it was made and published without my prior knowledge.

Affiliation : I am a professor of Computer Information Technology at Austin Community College in Austin, TX.
